This work with fish undoubtedly stimulated an interest in the general problems of respiration and combustion, and we may suspect that this was not unconnected with the interest that the Royal Society was then taking in the problems of diving. In 1664 we find Hooke giving an account of an experiment with two birds, one of which was kept in compressed air and the other in air at ordinary atmospheric pressure. He also constructed a container, large enough to hold a man, which could be partially evacuated by the air pump. Hooke experimented on himself in this device, thus anticipating modern investigations into human behaviour under reduced atmospheric pressure. He tells us that when a quarter of the initial air had been extracted he was able to endure for "somewhat above a quarter of an hour without any other inconvenience than feeling some pain in his ears, and finding himself deaf". During this experiment Hooke took a lighted candle into the container and discovered that it was extinguished long before he experienced discomfort. Other experiments carried out at this time involved the development of an air gun, the measurement of air pressure and experiments with diving bells; but the most important aspect of this period of experimentation is undoubtedly the insight which the use of the air pump gave Hooke into the mechanism of combustion and respiration. The culmination of this work was, in fact, the publication by Hooke in 1664, in "Micrographia", of his theory of combustion[5].

In 1680 Denys Papin, who invented the 'digester' (the prototype of the modern pressure cooker), joined Hooke as his assistant. He later developed a 'steam pump' in which water was forced, by expanding steam, into a container from which it was ejected, under pressure, on to the paddles of a water-wheel; and this has been regarded by some French authors as the first steam engine.

Papin's claims in this direction, however, must, one feels, rest on his contributions to the development of the atmospheric engine. For some time on the Continent there had been interest in the possibility of producing power by using the pressure of the atmosphere to force a piston along an evacuated cylinder. Various ways of producing the vacuum had been tried. Guericke[6] had described an experiment in which a cylinder had been evacuated by using his air pump; Huygens[7] had blown the air out of a cylinder by the detonation of a small charge of gunpowder; and Papin[8] had used the apparatus shown in Fig. 2 to produce a vacuum by the condensation of steam. Like many other members of the Royal Society at this time, Papin was aware of the enormous problem of clearing flooded mines

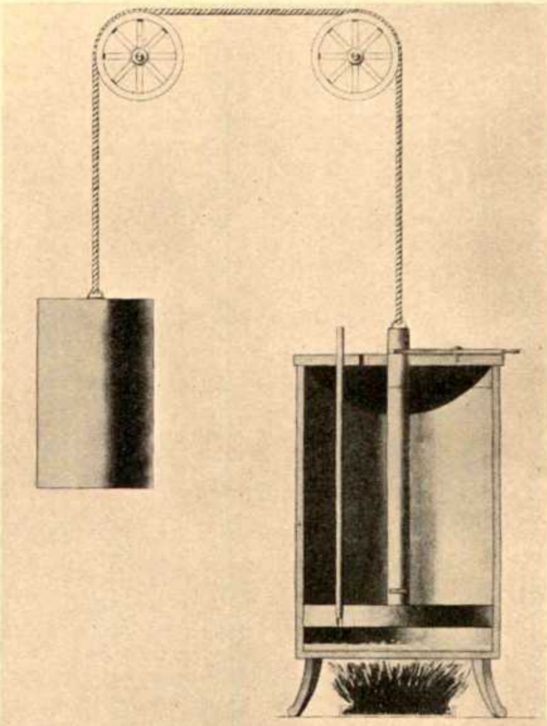

Fig. 2. Papin's cylinder and piston device, 1690. (*Crown copyright. From an exhibit in the Science Museum, South Kensington*) Steam generated by heat from the fire allowed the piston to rise to the top of the cylinder, where it was locked in position by the movable rod. The device was removed from the fire; the steam condensed by pouring cold water on the cylinder; and on releasing the piston it was forced down by air pressure, thus raising the counterbalanced weight

which were frequently distant from sources of water power In 1685 he proposed a scheme for the transmission of power over considerable distances A water-wheel was to drive two large air pumps , the air contained in pipes attached to these would be alternately rarefied and compressed , at the mine the suction and pressure would alternately lift water from the mine and then expel it In 1688 he proposed a modification of this in which a conveying pipe was to be evacuated by a water-driven air pump , at the mine the conveyance pipe was connected by branched pipes and valves to two vertical cylinders fitted with pistons , these were connected by ropes to an axle carrying a winding wheel around which was wound another rope carrying buckets at each end As each cylinder was evacuated in turn, external air pressure would force its piston down, thus turning the wheel first clockwise, then anticlockwise, and hence the buckets would be alternately raised and lowered

Hooke's influence on these projects and his contribution to the ultimate development of the atmospheric engine is now, unfortunately, undocumented Our only evidence of his interest and suggestions comes from references made by Dr Robison[9] of Edinburgh Among the latter's papers after his death was found a "List of Dr Hooke's Inventions" which contained the following sparse note, "1678 proposed a Steam Engine on Newcomen's principle", which implies that he had anticipated later developments in this field Robison also claimed to have seen, among the Royal Society's collection of Hooke's papers, memoranda of a letter addressed to Thomas Newcomen, of Dartmouth , these memoranda were, however, not in the possession of the Royal Society in 1880 According to Robison, Newcomen and John Cawley, a glazier, were anxious to make an engine on the lines suggested by Papin in 1688 Newcomen was in touch with Hooke and wrote to ask his advice Hooke had already criticized both Papin's projects on the ground that the great compressibility of the air in the conveyance pipe would result in negligible effects at the mine unless the water-driven pumps had inordinately long strokes In replying to Newcomen, Hooke said, "Could he [Papin] make a *speedy vacuum* under your second cylinder, your work is done"[10]

This suggestion was taken up by Newcomen and Cawley, who probably knew of Papin's piston and cylinder experiment and who certainly knew of the methods employed by Savery in operating his pumping machine, 'The Miner's Friend' According to Stuart[10], "They, therefore, made the experiment of introducing *steam* under a *piston moving in a cylinder, and formed a vacuum by condensing the steam by an affusion of cold water, on the outside of the steam vessel, and the weight of the atmosphere pressed the piston to the bottom of the cylinder*"

This method of producing a vacuum by the condensation of steam had been patented by Savery An agreement was therefore entered into between Savery, Newcomen and Cawley, and they were all associated in the grant of a monopoly for the atmospheric engine which was made in 1705

The construction by Hooke of the first efficient air pump undoubtedly exercised a profound effect on the development of science and technology in the second half of the seventeenth century Not only did the use of this machine lead to an understanding of the physical properties of gases and to a theory of combustion which is strikingly similar to the modern theory , but also it focused attention on the properties of systems of pistons and cylinders and the pressure of the atmosphere This was certainly important in providing the climate of opinion in which the atmospheric engine could develop , and as we have seen, there is reason to believe that in this development, too, Hooke played a decisive part

CANCER AND THE RESPIRATORY GRANA

By Prof. CARL C. LINDEGREN

Biological Research Laboratory, Southern Illinois University, Carbondale, Illinois

WARBURG'S[1] theory of the origin of cancer proposes that tissue specificity can be achieved only by the synthesis of substances which make tissues specifically different through oxidative metabolism in the grana which carry the oxidative enzymes Accordingly, the loss of tissue specificity begins with the loss of oxidative capacity through injury to the grana Since a source of energy is essential, the cell can only survive the loss of its oxidative apparatus if the oxidative apparatus is replaced by the adaptive development of the fermentative apparatus The loss of oxidative capacity is not reflected by an immediate loss of tissue specificity , but when the injured cell divides and the daughter cells begin to grow, they do not achieve tissue specificity because the energy produced by fermentative metabolism cannot produce it Warburg has focused attention on the oxidative grana of the cell , mutation, the carcinogenetic poisons, viruses, mechanical irritations, anaerobiosis, radiation and all other 'indirect' causes of cancer and influences, similar to hormonal control, are assumed to affect the autonomous grana and thus to affect tissue specificity only through their action on the grana Warburg has unified all ideas concerning the origin of cancer into a single concept involving material organelles capable of observation and metabolic investigation, thus making it possible to bring the phenomenon under test and observation. In this respect, the theory is (as Warburg says) the only explanation of the origin of cancer cells which can be "metabolically specified". The essential aspects of the theory are summarized by Warburg: "Cancer cells originate from normal body cells in *two* phases. The first phase is the irreversible injuring of respiration. . . . there is only one common cause into which all other causes of cancer merge, the irreversible injuring of respiration.

"The irreversible injuring of respiration is followed, as the second phase of cancer formation, by a long struggle for existence by the injured cells to maintain their structure, in which a part of the cells perish from lack of energy, while another part succeed in replacing the irretrievably lost respiration energy by fermentation energy. Because of the morphological inferiority of fermentation energy, the highly-differentiated body cells are converted by this into undifferentiated cells that grow wildly—the cancer cells."

Although Warburg's theory concerns the problem of dedifferentiation, it does not explain how the cell became differentiated. It has been pointed out by others that the cancer cell is not dedifferentiated back to the embryonic level but always retains some characteristics which make it identifiable with regard to origin. Thus the loss of tissue specificity does not involve complete but only partial 'dedifferentiation'.

Differentiation is also achieved in organisms in which defined cells do not exist, since the Ascomycetes, which are cœnocytial, are highly differentiated. Even though the nuclei flow freely through the false septa throughout the thallus, differentiation into mycelium, conidiophore and conidium is achieved in circumstances so fluid that no specific cell can be identified. This differentiation requires, like all other differentiation, the activity of many genes, since many nonconidial forms of *Neurospora* are known each of which is the phenotype of a different recessive allele. It may be inferred that differentiation is effected differently in cellular and noncellular organisms.

Although we all speak freely about 'yeast cells', it should be pointed out that phylogenetically yeasts are also noncellular organisms which graduate from mycelial or cœncytial forms to budding varieties all of which seem to be relatively closely related. The so-called yeast 'cell' and its bud is simply a cœncytial form which partitions single nucleate buds with a surrounding wall, much as *Neurospora* forms microconidia. Although this might seem like splitting hairs, it is a vital point in cell theory. The 'cell' that Warburg means is the cell of a multicellular organism.

A dominant scientific theory remains the dominant theory until it is replaced by a subsequent theory, because scientific effort can only be carried out under the ægis of a theory which restricts the activities and directs the efforts toward the examination of fundamental principles. Warburg's theory is to-day the dominant theory; by unifying the concept Warburg has made all other ideas concerning the origin of cancer subsidiary to his. In the absence of an alternative theory, one does not reject a theory by indicating extreme dissatisfaction with it (for example, Weinhouse[2]), since no scientific activity is conceivable without a guiding theory. The most adverse criticism notwithstanding implies acceptance *ipso facto*.

The first step in criticism of the theory is the specification of the assumptions upon which it is based. Warburg has assumed: (1) that the ascites tumour cell is a typical cancer cell; (2) that differentiation and tissue specificity in cellular organisms are achieved by oxidative metabolism of the grana (the respiratory grana have functions other than tissue differentiation, since they play an active part in the metabolism of yeasts); (3) that the grana are autonomous; and, therefore, (4) that the oxidative apparatus cannot be synthesized *de novo* (recent, unpublished, experiments in this laboratory have revealed that respiratory-deficient yeast cells, which never recover respiratory capacity spontaneously, can in certain unique conditions become respiratory-sufficient by exposure to yeast homogenates); (5) that cells which have lost oxidative capacity may obtain their energy by fermentation; (6) that division of these fermentative cells leads to the loss of tissue specificity, since they cannot obtain the oxidative energy essential to differentiation; (7) that such cells can neither fit into the tissue to perform the tissue function nor be restricted by the agents which restrict the differentiated cell and, therefore, form tumours; (8) that oxidative capacity can be injured (*a*) by oxidation of narcotics on the grana, (*b*) by direct action of specific poisons, (*c*) by anaerobiosis, (*d*) by radiation and (*e*) by various other items which are carcinogenetic. Research aimed at understanding cancer (as distinguished from applied research aimed at methods relieving the symptoms, study of surgical procedures, discovery of drugs for destroying cancer by large-scale canvasses, etc.) requires an investigation of the validity of these assumptions and a reformulation of theory depending on the results of such investigations.

Warburg's theory presupposes that the aerobic apparatus is a recent phylogenetical achievement. It is clearly a late, almost certainly the last, great advance made by the free cell in evolution, since it could only occur after photosynthesis had made oxygen available. Its recent integration into the cell probably accounts both for its autonomy and its vulnerability. (The respiratory grana and the chloroplasts are both autonomous structures which were obviously integrated into the cell recently, presumably before multicellular organisms evolved. It is reasonable to suppose that the chloroplast was the original symbiont added to the cell—or to the cœncyte—and that it later evolved into the respiratory granum with the advent of oxygen.) Since the autonomous aerobic apparatus seems universal, it may have been perfected when cells existed only as free cells, before the advent of the differentiated multicellular Metaphyta and Metazoa. The adaptive enzymic fermentation in yeasts, which is normally achieved by oxidative metabolism, may also be achieved by fermentative metabolism, albeit more slowly and less efficiently. Warburg might say that enzymic adaptation in single-celled micro-organisms is a 'cytoplasmic' activity and thus different from 'true' tissue specificity in multicellular organisms. On this theory, true tissue specificity may have appeared after the advent of oxygen.

A striking difference between yeast cells and mammalian cells lies in their means of obtaining energy. Yeast cells, unlike mammalian cells, have two separate fully functional systems for supplying adenosine triphosphate—an oxidative and a fermentative system. Yeasts can grow oxidatively or fermentatively without previous preparation, unlike the mammalian cells which can adjust themselves to a fermentative mode of existence only (according to Warburg) by slow degrees. In this sense, mammalian cells are almost obligate aerobes. No obligately aerobic yeasts are known since the anaerobic metabolism in yeasts is always available as a source of energy. In some yeasts (in which the aerobic pathway has been lost) the anaerobic pathway is the only source of adenosine triphosphate. Yeasts are markedly different from the filamentous fungi, like *Neurospora*, in which it is difficult to demonstrate the fermentative pathway and which resemble mammalian tissue in growing only poorly, if at all, under anaerobic conditions.

This discussion suggests that the yeast cell can provide a fruitful research object for study of the sensitivity of the respiratory apparatus and thus a guide in the evaluation of carcinogens. Many kinds of poisons have been tested with this view in mind. An interesting poison which was introduced to us by Dr. Seymour Hutner is propamidine isethionate. It is widely used in the tropics as a specific for kala-azar. It is thus important to know whether or not it may be carcinogenetic. Our present indications are that it destroys the respiratory apparatus too completely, too rapidly and too specifically to be a carcinogen—if the data from yeast cells are transferable to humans. When yeast cells are smeared on the surface of an agar plate, and a paper filter pad saturated with a solution of 1750 p.p.m. of propamidine isethionate is placed in the middle of the plate, a zone (several cm. wide) appears around the disk in which the yeast cells grow abundantly but in which none of the cells is capable of utilizing oxygen. Since the original cultures were respiratory-sufficient, it is inferred that propamidine isethionate has destroyed the respiratory apparatus. The living cells in the zone around the disk have been irreversibly transformed into obligate anaerobes. This is demonstrated by inoculating the cells from the zone into a peptone yeast-extract broth containing sodium acetate as the major source of carbon. The medium contains phenol red as an indicator, and if a single cell with an intact respiratory apparatus is introduced into this medium it will grow and the medium will turn deep red due to the increase in *p*H[3]. Although cells from the area surrounding the disk grow well in glucose broth, transfers to the acetate broth never produce an alkaline reaction, proving that all the cells have lost their ability to respire acetate and hence are respiratory-deficient. The conclusion that propamidine isethionate has destroyed the respiratory apparatus irreversibly seems irrefutable. It also appears to have achieved this end with relatively little harm to the cell otherwise.

This experiment is simplified by using a yeast which is incapable of synthesizing adenine, since strains of this kind with an intact respiratory apparatus are pink while the respiratory-deficient strains are white[4]. When this experiment is performed with a pink yeast, the yeast which appears in the zone surrounding the disk is white, although it remains adenine-dependent. White cells from such a plate always fail to grow after transfer to the acetate broth, justifying the inference that all the cells have lost their respiratory apparatuses since a single cell with an intact respiratory apparatus would be able to utilize the acetate and grow in the acetate broth. A poison of this type which acts abruptly and completely on the respiratory apparatus might be assumed on Warburg's theory not to be carcinogenetic because it acts so quickly and completely that the mammalian cells (which do not have a fully formed anaerobic pathway available and waiting) would not be able to adapt themselves to anaerobic growth. The phenomenon demonstrates the extreme sensitivity of the respiratory apparatus to a poison which has little or no effect on the survival of the cell.

Warburg's theory assumes that low oxygen tension can lead to crippling of the autonomous grana and thus to cancer. Warburg's inference that respiratory deficiency could be induced by anaerobiosis was confirmed by Hino and Lindegren[5] using yeast. (Respiratory-deficient yeasts, induced by anaerobiosis or by a variety of other treatments, are completely capable of maintaining their structural integrity permanently from generation to generation, although all the cell's energy is supplied only by fermentation. Warburg, quoting Pasteur, stated that "not even yeast, which is one of the lowest forms of life, can maintain its structure permanently by fermentation alone; it degenerates to bizarre forms". This view concerning the stability of yeast grown exclusively anaerobically is in error, but this fact has no bearing on the validity of Warburg's theory of the origin of cancer, since it neither supports nor invalidates any of the assumptions upon which the theory is based.) Both Sarachek[6] and Harris[7] failed to confirm the induction of respiratory deficiency in yeast by anaerobiosis. In three haploid cultures Hino and Lindegren found that the frequencies of respiratory-deficiency under aerobiosis were, respectively, 1·7, 2·8 and 3·2 per cent, while the same cultures grown anaerobically produced, respectively, 14·9, 8·6 and 8·0 per cent. Two diploid cultures under aerobic conditions produced, respectively, 0·8 and 0·0 per cent respiratory-deficiency, and 1·9 and 0·2 per cent under anaerobic conditions. In one tetraploid culture the frequency of respiratory-deficiency rose from 0·0 under aerobiosis to 0·3 per cent under anaerobiosis. It is clear that the haploid state provides the clearest demonstration of the effects of anaerobiosis on respiratory-deficiency, and it is not surprising that neither Sarachek nor Harris detected this effect, since they did not use haploid cultures. Anaerobiosis (unlike propamidine isethionate) induces only a low frequency of respiratory-deficiency; the effect of propamidine isethionate is total. Anaerobiosis produces relatively minor damages which might be progressive, if repeated, since only a few of the grana are affected in most cells and only rarely are all destroyed. Anaerobiosis is inferred to be an effective carcinogen, since it only reduces partially the energy available from aerobiosis and thus enables the cell to survive long enough to adapt the dormant fermentative system.

Recent work in this laboratory[8] has provided an example of another kind of induction of respiratory-deficiency in yeast. Caffeine induces respiratory-deficiency in yeast cells sensitive to caffeine with much higher frequency than in cells resistant to caffeine. Growth in caffeine is only achieved by an adaptive process, presumably an enzymic adaptation. Both resistant and sensitive yeast cells pass through the adaptation; but the adaptation of sensitive cells is characterized by the simultaneous induction of an extremely large number of respiratory-deficient cells. Although one may assume that the total induction of respiratory-deficiency by propamidine isethionate is due to the direct action on the grana, the induction of respiratory-deficiency which occurs when caffeine-sensitive cells become adapted to caffeine may be due to injury of grana, not by direct action of caffeine upon the grana, but through the metabolic stress imposed by oxidative adaptation to caffeine.

The metabolic stress of adaptation can be observed cytologically Several years ago when interest in the laboratory centred on adaptation of yeast to galactose, yeast cells were critically observed during adaptation In the early stage of adaptation most cells were not budded and did not stain with methylene blue (Non-stainability is the standard criterion for viability) Just before adaptation was achieved (as indicated (1) by the absence of budding , (2) by the failure to accumulate glycogen , (3) by slow utilization of galactose) nearly all cells became stainable with methylene blue In other circumstances this would indicate that the cells were non-viable Shortly thereafter, however, at least 80 per cent of the cells produced buds, lost their stainability with methylene blue, and vigorous fermentation of galactose occurred This is interpreted to mean that the stress of adaptation had exhausted most of the reducing reserves of the yeast cell, permitting it to stain with methylene blue, but that this deficiency was made up as soon as sufficient galactose became available

An important use of Warburg's theory is for predicting the possibility that an agent is a carcinogen from its action on the respiratory grana On this theory, propamidine isethionate is predicted not to be carcinogenetic whereas anaerobiosis and caffeine are The dye janus green, which acts specifically to stain the respiratory grana and which is singularly effective in preventing sporulation in yeasts, is predicted to be non-carcinogenetic Incidentally, the sporulative process in *Saccharomyces* is an especially useful point for testing the effectiveness of various toxic agents on the respiratory grana, since it is a highly specific kind of differentiation which is achieved only aerobically The view that viruses may cause cancer can also be deduced directly from Warburg's theory Warburg inferred that a great variety of metabolic disturbances could inactivate the respiratory apparatus, and experimental evidence from yeasts supports his views Since many viruses grow in the cytoplasm without killing the cell, they are disturbers *par excellence* of cytoplasmic metabolism and might be expected readily to cause the destruction, inactivation or malfunction of the grana Viruses inhibiting the nucleus would be predicted to be not nearly so effective

Ephrussi[9] was the first to speculate concerning the chemical mechanism by which the respiratory grana of the yeast cell could be destroyed He assumed that since acriflavine has an affinity for nucleic acids it was mutagenic and he found that it induced respiratory deficiency Ephrussi was unaware of the fact that Stier and Castor[10] had previously induced respiratory deficiency with cyanide, and Whelton and Phaff[11] had shown that ethylene oxide is extremely efficient in producing the same effect It has become increasingly evident that a great variety of substances induce respiratory deficiency in yeasts copper and manganous salts are recent additions Whether these substances act directly as propamidine isethionate appears to, or indirectly as temperature[12] and caffeine adaptation, it seems clear that study of the phenomenon should be revealing in terms of the nature of the respiratory grana and, therefore, of carcinogenesis

This work has been supported in part by a research grant from the American Cancer Society

THE NEW MARINE BIOLOGICAL STATION ON HELIGOLAND

By Dr J. N. CARRUTHERS

National Institute of Oceanography, Wormley, Surrey

MANY years before the island of Heligoland passed from British to German ownership in 1890, it was popular with distinguished scientists from Germany and other Continental countries for marine biological pursuits, because the waters bordering the German mainland yield only a small part of the faunal range characteristic of the open sea

In the Baltic, the low salinity of the German waters there is a limiting factor and in the North Sea the turbidity is such Moreover, in the North Sea the wide belt of mainland shore which dries out at low tide militates against the establishment of a first-rate German marine biological station there Well before 1850, men whose names were to become world-famous in the domain of marine biology were frequenting Heligoland because of the much better natural conditions which exist there

So long ago as 1835, Ehrenberg had investigated the origin of bioluminescence while working on the island and, ten years later, Johannes Muller had there formulated new ways of investigating the life of the open sea In 1865 Anton Dohrn (later of Naples fame) and Ernst Haeckel of Jena were conducting researches from the island, and, within two years of its cession to Germany, a marine biological station had been founded with F Heincke as first director During the twenty-eight years of his tenure of the post, his famous work on the natural history of the herring and on the plaice was carried out In those days the Station was housed in more than thirteen separate buildings and its own staff of eight scientists and sixteen technical assistants had to find room for sixteen guest workers Not until it was possible (in 1920) to take possession of a large building freed from naval use did it become possible to conduct tuition courses, and the first of these was attended by a class of thirty

Many British oceanographers will well remember Heincke's successor—the genial and talented W. Mielck, who was head of the Station during

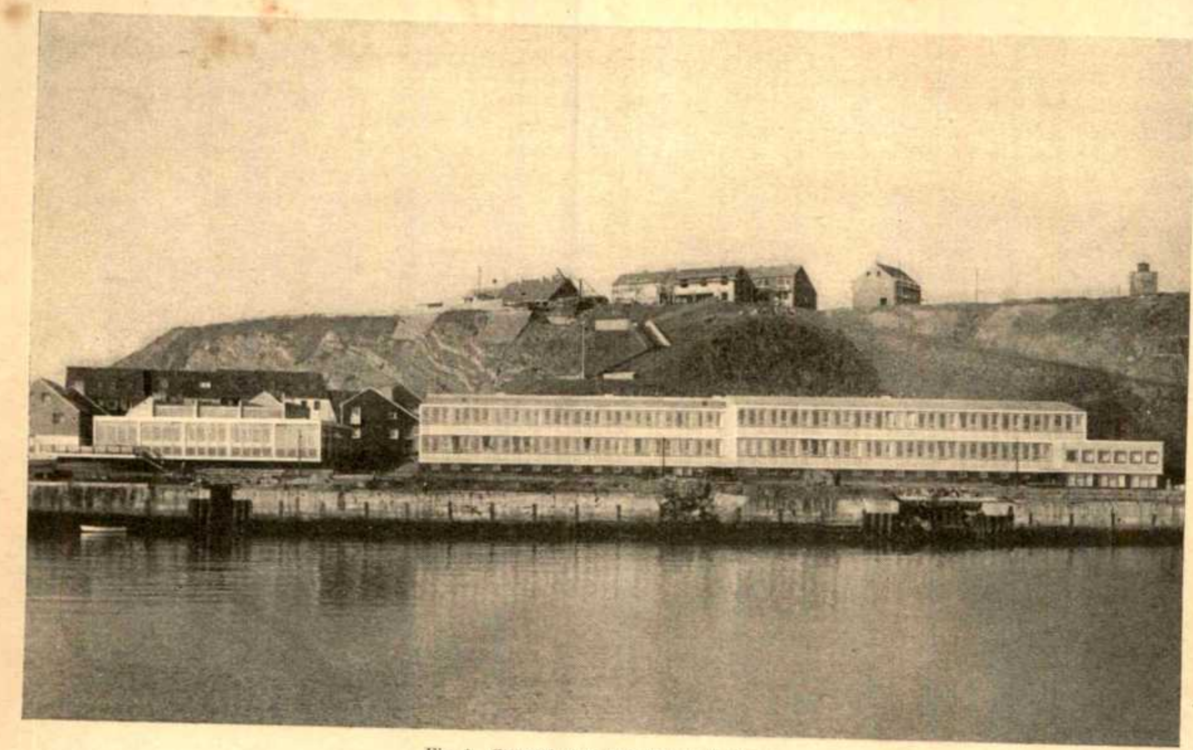

Fig. 1. General view from the water front

1920–33. When its enlargement was completed in 1937, the name "Wilhelm-Mielck-Haus" was given to part of the multi-storied construction. The last director of the Station to be appointed before the Second World War was A. Hagmeier, who held the post on the island from 1934 until after hostilities had broken out. He remained the nominal director of the Station until his death in 1953. Until shortly before that time, he had been resident in Sylt at the dependent Ellenbogen Station near List. While there Hagmeier spent much effort in the furtherance of marine biological research and was able to adapt a vacated army building in List to provide a two-roomed laboratory on the harbour side in which instructional courses could be given. Already by 1949 the number of visiting students had reached 170. When, in 1952, the island of Heligoland was made free of access again and declared ready for building operations to start, Hagmeier was already prepared with plans for reconstituting the renowned Biologische Anstalt on it. Though it is not by any means the case that all German marine scientists were in favour of the project, the marine biologists for the most part were so.

In pre-1939 days, the "Biologische Anstalt Helgoland" came under Prussia and one may read, in old reports of the Government, of that State having furnished 400,000 marks for the rebuilding which began in the winter 1925–26. when serious thought was given to rebuilding the completely demolished Station some years after the end of the Second World War, however, the island had come under Schleswig-Holstein. This *Land* not being financially able to shoulder the expense of such an ambitious project, it came about that the *Bund* Ministry of Land, Food and Forests eventually did so.

Much space would be needed to give an adequate account of the impressive proceedings of June 19 last, when the fine new Station which has arisen on the ruins of the old was formally declared open in the presence of a large concourse headed by Bundesminister Dr. Lübcke, who has since been elected President of Western Germany in succession to Dr. Heuss. Ministers of Schleswig-Holstein were present; German oceanographers were there in number; guests from the Netherlands, Italy and Britain attended, and an English fisheries research vessel (*Sir Lancelot*) had come from Lowestoft. The Director of Fisheries Research in Britain was present, greatly to the gratification of Dr. A. Bück-

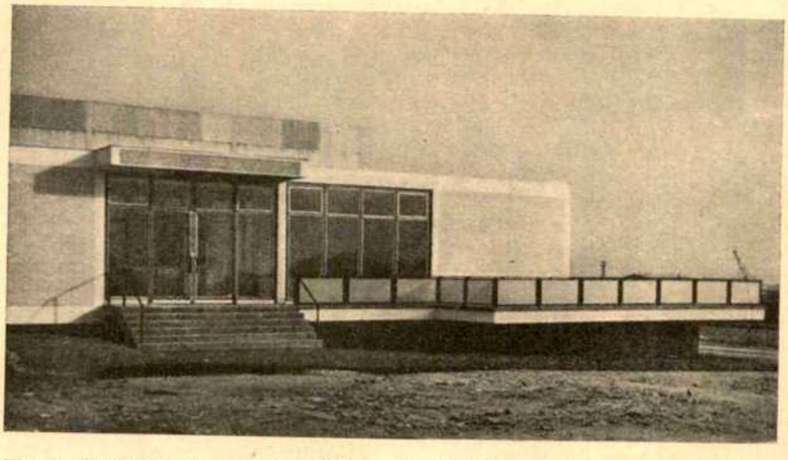

Fig. 2. Entrance to the aquarium with (on the right) the verandah around the seal basin

mann, director of the new Station, who recalled the close associations between Lowestoft and Heligoland during the years between the wars. Most of the guests had been carried from Cuxhaven in the very fine German research vessel *Anton Dohrn*, which has already much first-class work to her credit despite her youth.

Speeches and a tour of the new Station were the business of the first day—followed by a reception and supper aboard the *Anton Dohrn*. The second day (June 20) was devoted to a scientific conference in the commodious lecture room. After a *Festvortrag* by Dr. J. Verwey of Den Helder, he opened a general discussion on what should be the scientific activities of marine stations. After this topic had been debated very widely with no lack of participants, Dr. A. Bückmann gave a very detailed account of the programme of work which he has in view for his fine new Station. From what he said it was quite clear that great care had been taken to build as economically as possible in erecting the long low buildings which are such a contrast to those standing when the former building programme ceased in 1937. Because practically everything had to be transported from the mainland at great additional expense and with dependence upon weather, it is perhaps not surprising that the cost to the *Bund* Ministry was in the neighbourhood of six million D.M. (about £6/11 million).

The divisions of activity provided for under the general leadership of Dr. A. Bückmann, who remains resident in Hamburg, where he is professor of fisheries biology in the University of Hamburg, are : zoology, animal physiology, botany, microbiology, planktonology and fisheries biology. The first of these divisions has a staff of three scientists with the Director as leader. The other divisions have two scientists each, except for microbiology, which has only one. It seemed surprising that there is no special provision for the hydrographical work which is essential before a proper study can be made of the relationships between the marine fauna and flora and the environment. An island like Heligoland must afford wonderful opportunities for studying what differences exist in the marine life as between what must usually be the lee and weather sides.

There are many things of great interest with which a worker trained in the physical side of oceanography could occupy himself working from the new Station. Questions elicited the remarks that expense had to stop somewhere, but that visiting workers on any aspect of oceanography would always be made most welcome—as evidenced by the great amount of laboratory space set aside for guests.

It is a very praiseworthy feature of post-War German marine science that excellent collaboration exists between the Heligoland activities led by Dr. Bückmann, the German Hydrographic Institute, the German Scientific Commission for Marine Research, the Institute for Fisheries Biology of the University of Hamburg, the Bremerhaven Institute for Marine Research and the University of Kiel. This close working together has led to really notable achievements in respect of investigations on the high seas, and German oceanographical investigations made during the Polar Front Survey within the International Geophysical Year programme are of high merit.

Along the southern face of the main block of the new Station are the laboratories in use by the staff and the rooms used for the dispatch of animals to universities and other customers. The northern face contains the laboratories for guest workers and students. The public aquarium, with all its complicated technical 'plumbing', and the aquaria for research and growth studies constitute a separate block. An impressive feature of the aquarium which those with memories of the pre-War Station will recall has been provided anew and in duplicate. Quite detached and centrally placed are a pair of circular 'tanks' in the form of very large glass vertical cylinders rising to a considerable height from the floor. Co-axially placed within each of them is an opaque vertical cylinder of considerable diameter which has a sanded surface. As a result, fast-swimming fish such as herring, mackerel and hake can swim swiftly around and around in the annular water space without knocking into the external glass or being crowded into corners. It is a wonderful sight to see the fish incessantly swimming around on their (to them) endless journey. Great value is attached to the fine supply of excellent sea-water pumped in from the end of a mole, and to the fact that all the 'plumbing' is of plastics. One sees handsome arrays of bright green and red piping more or less everywhere. The Station's cutter *Uthorn*, which is 24·5 metres long, of 6·4 metres beam, and of draught 2·6 metres, does 8 knots under the drive of her 150 h.p. engine. She is excellently equipped with instruments and is of great use in enabling the scientists to dredge in the Heligoland Rinne, which is one of the deepest parts of the southern North Sea and has a fauna of particular interest. Two motor-boats are also available.

It was emphasized that to run a marine biological station to-day is a vastly different affair from what it was in Anton Dohrn's day. The mass of expensive and costly apparatus which had already become necessary a decade and more back has been much added to by the requirements for work with carbon-14 and other isotopes. The new Heligoland Station is well equipped for work with eight or more tracer elements.

Heligoland was always a favourite holiday resort, and already some eleven hundred permanent inhabitants are housed again on the island to make the most of it. 'Day tripping' from the mainland is also a very intense and paying business. During the summer the multitude of visitors contribute to the Station's funds by way of their payments to visit the aquarium. In winter when the visitors no longer come, the scientists of the Station can use the large annular 'tanks' described above of 25 m.^{3} capacity for studies on the swimming of migratory fish.

About fifteen guest investigators pursuing quite different lines of work can work in association with the thirteen scientists of the Station, and great help is given in the matter of lodging to guests whose visits take place in summer. By throwing two large classrooms into one, thanks to a movable partition, a lecture room with ample accommodation for fifty students becomes available. Provision is made for visiting university teachers to bring students to the Heligoland Station for classes lasting some weeks, and facilities are afforded for teachers of biology and others to attend refresher couses.

The complex of buildings, which has a total frontage of 120 metres, includes a special basin in which a seal will live. This, with glass 4 cm. thick, is most ingeniously constructed. Outside, walking on a balcony, paying visitors will be able to look down on the seal from above. From inside the building the visitors will look into the tank illuminated by daylight from above, and will see many smart movements imposed upon the seal by the clever internal 'architecture' of the tank. This fine basin recalled the modest accommodation which the seal living in the Heligoland aquarium many years ago had to be content with.

As with the Station of former times, the very appropriate speech from Goethe is in evidence. It now faces us set into the wall in large bronze capitals as we enter through the main public door "Alles ist aus dem Wasser Entsprungen, alles wird durch das Wasser erhalten, Ozean gonn uns Dein ewiges Walten".

It was due to the kind generosity of the *Bund* Ministry that I was able to attend the impressive re-opening. For those who would know very much more about the new Biologische Anstalt Helgoland, a full account written by its director exists[1] and a shorter one by one of his assistants[2].

OBITUARIES

Prof. E. Percival

A GREAT blow has been dealt to marine and freshwater biology in New Zealand by the death on July 15, in Christchurch, of Prof. Edward Percival. Prof. Percival, who was born in 1893, was elected to the chair of biology at Canterbury University College, as it was then called, in 1928 after serving as lecturer in the Department of Zoology at the University of Leeds, where he was assistant to the late Prof. Walter Garstang. During 1928 he worked as a temporary naturalist in the Plymouth Laboratory on the ecology of the Rivers Tamar and Lynher, and he will be well remembered by those who knew him then. The son of a Cheshire farmer, Percival spent his boyhood in Lancashire, where he took the national diploma in agriculture at the Harris Institute, Preston, and he found much to interest him when he came to New Zealand. His early work on the ecology of rivers in Yorkshire led him to play a prominent part in trout management in acclimatization society work in New Zealand, and his experience in marine biology in the United Kingdom was put to good use in guiding his research students and in advising the policies of various government departments.

His published work, amounting only to about a score of papers, is not a sufficient criterion by which to judge the man. He had declined various academic honours since he maintained that such things were of no use to him. He did, however, consent to be elected a Fellow of the Royal Society of New Zealand.

First and foremost he was a teacher. From the elementary- to the postgraduate-level he never failed to bring out the best in the human material set before him. His particular philosophies on the teaching and appreciation of biology will be long remembered by all those who came in contact with him, even if only as incidental associates.

For his advanced students he held a twice-yearly field expedition to Menzies Bay, one of the isolated little coves on Banks Peninsula, and he took his students into the field on almost every other week-end during term, bringing a certain spartan approach to the pleasures of animal observation which helped one more fully realize what is meant by ecology. His aim was to produce, at the postgraduate-level, a student well balanced in outlook, able to think, not to be a storehouse of facts but to know where to turn to find what is already known, and potentially able to go on in almost any field of biological endeavour. How successful he has been in this can be seen by the wide distribution of his honours students in various positions throughout the world.

The informal, and often quite unzoological, discussions which he held in the field and in the well-remembered atmosphere of his rooms, together with his novel methods of allowing notes to be taken into the examination room, all helped to bring out what powers of expression and thought were available in his students. Indeed, he often remarked that he wished he could conduct his examinations in the University library, for he would know even more easily the worth of his candidates.

Physically he was outstanding for a man near retirement, and in the field his stride and energy in every activity proved more than a match for even the most athletic of his followers.

At the first encounter he presented a rather forbidding aspect and was inclined to be of uncertain temperament, but this, particularly in his later years, was a variation on the theme of not suffering fools gladly. If one genuinely wanted help, advice or encouragement and if one had exercised all one's resources before approaching him, Percival became the proverbial tower of strength and it was difficult not to find oneself being cast in his mould.

Apart from his long-term studies on lakes in the Canterbury foothills and his interests in marine matters, his scientific work will long be remembered for his fine studies on the embryology of the Brachiopoda. Percival was fortunate in having a locality close by where these animals could easily be taken between tides on the rocky shore and he was able to use his advantage to the full in producing his studies on their development and growth. He was never afraid to admit that he was wrong or that he did not know, an attitude of mind which had its effects particularly on his elementary students contemplating a career in teaching.

Percival's influence extended far beyond the cloisters of the University of Canterbury, and it would be hard to exaggerate just how widely his teaching and stimulation have been, and will continue to be, felt.

ELLIOT W. DAWSON

Dr M. R. Schafroth

DR MAX ROBERT SCHAFROTH and his wife, Kathi Schafroth (*née* Gemperle), died on May 29; they were killed in an aeroplane crash in Northern Queensland, Australia.

Dr Schafroth was born in Burgdorf, Switzerland, on February 8, 1923. He passed his matriculation at the Gymnasium in Bern in 1949. He then entered the University of Bern in order to study mathematics and physics, later changing to the

Swiss Federal Institute of Technology in Zurich. He graduated at the latter in 1948, obtaining a diploma in mathematics and physics.

Thereafter he commenced research work under the direction of Prof. W. Pauli, who was professor of theoretical physics at the Institute and Nobel prizewinner of 1944. Dr. Schafroth obtained his doctorate degree in 1949 and was thereafter appointed as assistant to Prof. Pauli—a post he held until 1953. During that time he continued research in collaboration with Prof. Pauli in quantum field theory and solid state physics.

At this stage the Schweizer Arbeitsgemeinschaft fur Mathematik und Physik offered him an overseas travel grant for two years, which he decided to spend in the Department of Theoretical Physics of the University of Liverpool with Prof. H. Frohlich. After one year in Liverpool, however, he left Europe to accept a lectureship offered him by Prof. H. Messel in the then newly expanded School of Physics at the University of Sydney. He remained at the University of Sydney until his death, having been promoted to a senior lectureship on January 1, 1955, and to a readership on January 1, 1957. In May 1958 he was invited to accept the chair of theoretical physics at the University of Geneva, Switzerland, which invitation he had accepted and intended taking up this post on September 1, 1959.

Starting mainly with his stay with Prof. Frohlich in Liverpool, Dr. Schafroth became interested in the theoretical understanding of the phenomenon of superconductivity. This was also his chief research interest during his five years at the University of Sydney. He published several penetrating papers on this subject himself and also inspired contributions from others in the School. There can be no doubt that his work in this field will go down in science as having been a major contribution to the understanding of superconductivity. Several papers by him are yet to appear. These include a review of the field in the series "Solid State Physics", edited by Profs. Seitz and Turnbull.

Apart from this particular field of research, Dr. Schafroth was an expert and inspiring lecturer in the fields of statistical mechanics, solid state physics in general and quantum field theory. He brought into his lectures something of the qualities of his old teacher, Prof. Pauli.

The death of Robert Schafroth and of his wife Kathi will be a great loss to all who knew them.

S. T. BUTLER

Mr. H. W. Greenwood

THE death of Mr. H. W. Greenwood occurred on April 30 at the age of seventy-seven. In the course of a very active life, Mr. Greenwood was associated with three industries. Before the First World War he was a mining plant superintendent in the south of Spain. In 1919 he joined Leto Photo Materials Company, manufacturers of photographic paper, and continued with the firm after their amalgamation with Wellington Ward and their later amalgamation with Ilford, Ltd. Since 1937 he had been associated with Powder Metallurgy, Ltd.

Mr. Greenwood wrote profusely in all three subjects, papers and books of a popular but well-informed nature. For many years he was an important contributor to the *British Journal of Photography*.

W. D. JONES

NEWS and VIEWS

Electrical Engineering at Newcastle upon Tyne: Prof. J. C. Prescott

PROF. J. C. PRESCOTT, professor of electrical engineering at King's College, Newcastle upon Tyne, retires this year. He was elected in 1937, succeeding W. M. Thornton, who was the first holder of the chair. After studying at the University of Liverpool under Prof. E. W. Marchant, he entered a college apprenticeship with the British Westinghouse Company in 1915, continuing later with that Company as research engineer. He saw service with the R.N.V.R. during the First World War, being attached to H.M. Mining School at Portsmouth. After the War, he returned to the University of Liverpool as lecturer in electrical engineering, where he was to remain for 18 years. His early researches were concerned with the behaviour of constant-current dynamos, and this led by way of a study of the free period of coupled alternators to researches on the inherent instability of parallel connected synchronous electrical machinery. His papers of this period reveal that electrical measurement and measuring instruments were also occupying a substantial part of his time. For this work he was awarded the degree of doctor of engineering by the University in 1931. In Newcastle his research work has been concerned with synchronous governing of alternators, and further studies of the stability of parallel-connected alternators have been made; latterly he has been engaged in an investigation into the performance of turbo/alternator governors, which is still in progress.

The Department of Electrical Engineering at Newcastle has grown greatly in size during Prof. Prescott's tenure of the chair. Under his direction the expansion has been conducted so as to preserve a balance between so-called 'light' and 'heavy current' electrical engineering, and to avoid too early specialization in undergraduate courses. Always playing a large part in the teaching activities of his Department, he has consistently emphasized the necessity for the teaching of fundamentals in university courses, and has always insisted upon the maintenance of a high academic standard in his Honours School. Like his predecessor, he has been active in the affairs of the Institution of Electrical Engineers, being chairman of the North Eastern Centre in 1943–44, and has taken a continued interest in the North East Radio and Measurements Group. Coming from a literary family, he is a man of uncommonly wide interests who holds the respect and affection of all who know him. His friends both inside and outside the University wish him many years of active and happy retirement.

Dr. R. L. Russell

DR. R. L. RUSSELL, who has been appointed to the chair of electrical engineering at King's College, Newcastle upon Tyne, in succession to Prof. J. C. Prescott, graduated B.Sc. in 1938 and M.Sc. in 1939, in mathematics at the University of Leeds. Soon afterwards, he took up work in the Admiralty Degaussing Department at Portsmouth and Helensburgh, and thus his first contacts with electrical engineering were made. In 1942, when the magnetic mine had been overcome and there was an acute demand for radio mechanics, Dr. Russell accepted lectureships on radio training courses, first at the Royal College of Science and Technology, Glasgow, and then at Robert Gordon's Technical College, Aberdeen. He went from Aberdeen to the Research Department of the British Thomson-Houston Co. at Rugby. In 1946, he was appointed as lecturer in the Department of Electrical Engineering in the University of Bristol, and in 1955 he was promoted to a readership.

Towards the end of the War he published certain papers of a semi-geometrical nature, mainly arising out of problems in radio engineering. As time has proceeded, he has turned his essentially geometrical mind to a number of problems, first in electrical measurements and then in relation to electrical machines. Many papers have been published in the *Proceedings of the Institution of Electrical Engineers* arising out of this work, which led to Russell receiving the degree of D.Sc. from the University of Leeds a few months ago. Dr. Russell's most individual contribution to electrical engineering has been to observe the possibilities which arise from feeding a three-phase winding simultaneously at both ends with voltages of different frequencies. This principle has already had several applications, and it is of interest to note that Russell's predecessor in Newcastle, Prof. J. C. Prescott, adopted the idea in relation to synchronous governing. A recent Ph.D. thesis on synchronous governing presented at King's College incorporated just such a double-fed device.

Agricultural Botany at Leeds: Prof. J. H. Western

Dr. J. H. Western has been appointed to the newly instituted chair of agricultural botany within the Department of Agriculture in the University of Leeds. He was educated at Avoncroft Agricultural College, Evesham, and the University College of Wales, Aberystwyth, where he graduated in botany with agricultural botany. In 1937 he was awarded the degree of Ph.D., the subject of his thesis being "Some Aspects of Biological Specialization in the Oat Smut Fungi". In that year, he also took up an appointment at the Welsh Plant Breeding Station, Aberystwyth, where he undertook research on diseases affecting herbage plants. In 1939 he was appointed lecturer in agricultural botany and adviser in mycology in the University of Manchester, leaving in 1946 to take up appointment as provincial plant pathologist to the Northern Province, Ministry of Agriculture and Fisheries, Newcastle upon Tyne. In 1951 he was appointed to his present post of senior lecturer in agricultural botany in the Department of Agriculture in the University of Leeds. His investigations have included the problem of the 'choke' disease of cocksfoot (*Dactylis glomerata*) caused by the fungus *Epichloe typhina*, and he has been responsible for numerous publications.

Physiology at King's College, London: Prof. R. J. S. McDowall

The retirement is announced of Prof. R. J. S. McDowall from the Halliburton chair of physiology at King's College, London. This he has held for thirty-six years. He has perhaps become best known for his books. The most outstanding is "Control of the Circulation of the Blood", a monumental work with more than 9,000 references; but his "Handbook of Physiology", of which he has produced eleven editions, has been the bible of a generation of medical students. His "Sane Psychology" has been reprinted four times. Prof. McDowall's interests have been chiefly in the circulatory system in which he has been an untiring worker and is a recognized authority. He gave the Oliver Sharpey Lecture of the Royal College of Physicians in 1939 on this subject. He has also been largely responsible for the formation of the Asthma Research Council and in recognition of this he was made president of the fourth European Congress of Allergy held in London in September. His enthusiasm and powers of inspiration are reflected by the fact that thirteen of his pupils have become professors and, of these, six have been in the University of London.

Prof. J. L. D'Silva

Prof. J. L. D'Silva has been appointed to succeed Prof. R. J. S. McDowall. Prof. D'Silva first graduated in 1929 from King's College in chemistry. His early interests were in organic chemistry and he was elected Sir Halley Stewart Fellow in 1933. His attentions then turned to physiology, and appointments leading to the readership in physiology at St. Bartholomew's Hospital Medical College followed. Here he pursued his particular interests in the effects of adrenaline and adrenaline-like substances on serum electrolytes. In 1948 he was appointed to the chair of physiology at the London Hospital Medical College where his research contributions to the understanding of respiratory mechanics again reflected his early interest in the physical sciences.

University of Malaya in Kuala Lumpur: Prof. R. S. Huang

In the article under the title "University of Malaya in Kuala Lumpur" in *Nature* of August 1, p. 306, it was stated that Prof. R. A. Robinson had been appointed to the chair of chemistry. It has now been announced that Prof. Robinson has declined the appointment, which has been accepted by Prof. R. L. Huang, reader in chemistry in the University.

Prof. Rayson Lisung Huang was educated in Hong Kong, first at Munsang College and then at the University of Hong Kong. After a year as demonstrator in chemistry at Kwangsi University, China, Dr. Huang went to the University of Oxford with two scholarships, from the Rhodes Trust and the British Council, to study under Sir Robert Robertson. He gained his doctorate as a result of this period of research on synthetic hormones. Dr. Huang then visited the University of Chicago with a postdoctoral fellowship and studied for two years under the late Prof. M. S. Karasch, and then joined Prof. Konrad Bloch as a research associate for a further year. During these periods Dr. Huang worked on free radicals and on the biosynthesis of cholesterol, respectively. He joined the University of Malaya early in 1951 and has been awarded the degree of D.Sc. for his researches mainly in the field of free radicals. A citizen of the United Kingdom and Colonies, Dr. Huang has a good knowledge of classical and modern Chinese, and speaks several Chinese dialects. His scholarship in a wide field will be a most valuable contribution to the professoriate of the new Division of the University of Malaya.

The Second Russian Space Rocket

A Russian multi-stage rocket was launched at about 9 hr U.T. on September 12 and its final stage, weighing 1,511 kgm. (3,331 lb.) when empty of fuel, was projected towards the Moon with a speed of 7 miles per sec. At 18h. 40m. U.T. on September 12, when it was about 90,000 miles from the Earth, the vehicle emitted a cloud of sodium vapour. This was observed from eastern Europe and Asia as a glow, which lasted about 5 min. and was of stellar magnitude 5, in the constellation of Aquarius. At an unspecified point on its journey, the vehicle divided into two parts, an instrumented sphere weighing 390.2 kgm. (860 lb.) and the spent rocket. The sphere carried instruments to measure the magnetic fields of the Earth and Moon, the zones of radiation around the Earth, cosmic rays in space, the impacts of micrometeorites and the composition of interplanetary gas. It was stated that these experiments were successfully accomplished. The vehicle carried radio transmitters operating on some of, or all, the frequencies 19.993, 19.997, 20.003, 39.986 and 183·6 Mc./s. The radio signals ceased abruptly at 21h. 02m. 24s. U.T. on September 13, when the instrumented sphere struck the surface of the Moon at long. 0°, lat. 30° N., near the crater Archimedes.

While the vehicle was above the horizon in Britain, it was tracked by the Jodrell Bank radio telescope; the measurements made, of the direction, the Doppler frequency and the moment of impact, all confirmed that the vehicle followed very closely the trajectory given by the Russians. This second space rocket was similar to the first (launched on January 2, 1959; see *Nature*, 183, 83), which had a total weight of 3,245 lb., including 797 lb. of instruments in a spherical container, and performed similar experiments. The trajectories of the two rockets were also similar—both took about 35 hr. to reach the vicinity of the Moon—though the first rocket, instead of colliding with the Moon, flew past it to become the first artificial planet.

Rocket Studies of Emissions caused by Solar Flares: National Science Foundation Grant

The National Science Foundation has made a grant of 250,000 dollars to the U.S. Naval Research Laboratory for rocket observations of ultra-violet and X-ray emissions from solar flares. Principal investigator of the project is Dr. Herbert Friedman, superintendent of the Atmosphere and Astrophysics Division of the National Research Laboratory. The effect of the Sun's emissions upon the ionosphere and the resulting radio communication problems are of great theoretical and practical significance. Measurement and understanding of the origin of these emissions will be basic to an understanding of the solar flares themselves. Dr. Friedman will therefore launch a series of instrumented *Nike-Asp* rockets to make the necessary observations. The investigation will explore wave-lengths and altitudes at which only rudimentary observations have so far been made. Previous work by Dr. Friedman, Dr. Richard Tousey, and their co-workers at the National Research Laboratory has established the existence of intense radiations from the Sun in the wave-length regions under consideration. Dr. Friedman and his group at the Naval Research Laboratory were pioneers in the use of rockets for astronomical research, and astronomers credit his work with being among the most exciting and significant at present being carried on in the field. Instrumentation for the series of rocket observations will include Geiger counters to measure X-rays in the 1–10 A. range, X-ray detectors for wave-lengths of 8–20 and 44–60 A., scintillation counters sensitive to hard X-rays in the 20–500 kV. range, and ion chambers sensitive to the helium emission lines at 584 and 314 A.

British Aid for Nato Scientific Courses

Mr. H. Nicholls, Parliamentary Secretary to the Ministry of Works, stated in the House of Commons that the United Kingdom contribution to the fund established by the North Atlantic Council to promote international gatherings for the advanced study of special scientific topics would be about £7,000 in the first year and would be borne on the vote of the Department of Scientific and Industrial Research. This was a written answer on June 25 in response to a request for a statement regarding United Kingdom participation in the new North Atlantic Treaty Organization scheme for advanced study institutes. The funds would mostly be used for contributions to the teaching and administrative expenses of selected courses at institutes in a Nato country which offered intensive courses, usually at postdoctoral to professional level, in branches of the natural sciences and technology. Assistance might also be given to the travelling and scholastic expenses of participants from Nato countries.

Graduates and National Service

In answering a question in the House of Commons on June 8, the Minister of Labour, Mr. Ian MacLeod, said that he was not prepared to extend the deferment arrangements for science and engineering graduates to men with other qualifications. This was the advice of his Technical Personnel Committee, which had considered last autumn difficulties said to be created for firms engaged in nuclear engineering and other industries by the call-up of non-graduates engaged on research. It was extremely difficult to distinguish between all the different professional qualifications that non-graduates have, but Mr. MacLeod said he would be willing to receive a deputation of research directors to discuss a definition which might be as effective as the graduate definition, if Mr. Blenkinsop, his questioner, cared to organize such a deputation.

Research and Development Charges in Civil Nuclear Power

A question was asked in the House of Commons on June 15 regarding the proportion of research and development charges for the civil nuclear power programme borne by public funds through the Atomic Energy Authority. The Paymaster General, Mr. H. Maudling, in reply said that all research and development expenditure incurred by the Atomic Energy Authority was originally borne from public funds. However, it was intended that the expenditure attributable to the civil power programme should be recovered in due course in the form of royalties payable on the electricity stations and as part of the price charged for fuel elements. The Authority also recovered the cost of the consulting services from the electricity boards.

Nuclear Reactor *RB* Accident in Yugoslavia

Volume 9 of the Bulletin of the Boris Kidrich Institute of Nuclear Sciences contains twenty-five articles and two laboratory notes of technical interest contributed by members of the physics, physical chemistry and radiobiology laboratories of the Institute They are prefaced by a statement in French by the director of the Institute, Prof P Savić, concerning the unfortunate accident which occurred to the nuclear reactor, *RB*, on October 15, 1958, at the Institute Six people, who were very close to the reactor, received strong doses of neutron and ionizing radiations and two others, who were not so close, doses above the permissible level The six were given medical treatment at the Curie Hospital in Paris, but one, V Zivota, a nuclear physicist, died on November 15 The reactor, *RB*, is of zero energy and is fuelled with natural uranium and moderated with heavy water Details of the construction of the reactor are given in the first article in the volume The safety system consists of a control key, safety rods, alarm dose-rate meters and an automatic shut down The approach to criticality is made by gradually raising the heavy-water level The accident occurred when the reactor went out of control in becoming critical Prof Savić includes in his statement the conclusions of the committee of inquiry set up by the president of the Federal Commission for Nuclear Energy to report on the accident On October 15, the committee reports, neither the alarm dose-rate meters nor the automatic control were functioning, and the personnel were judging the state of the reactor by the amount of ozone they could smell in the air The rise in power of the reactor had been detected by the strong increase in gamma-radiation, within an interval of ten minutes, on automatic recorders of the activity in the atmosphere, placed at 540 metres from, and in direct line with, the reactor An estimate of the radiations received by the injured persons is given in the article and shows that a total dose of about 683 rems was received, of which about 388 rems was by neutrons The amount received individually varied according to the distance of the person from the reactor, and was about 15 per cent less than the quoted value for the farthest distant.

The Japanese Nuclear Power Station

THE March number of the General Electric Company's *Atomic Energy Review* (2, No 1) includes an artist's impression of the 150-MW nuclear power station designed to be erected at Tokai Mura, 65 miles north-east of Tokyo, and which will be Japan's first nuclear power station The General Electric Co Ltd has been selected exclusively to negotiate a contract for its erection The station will be powered by a single gas-cooled graphite-moderated reactor of the same basic type as the two reactors at present being built at Hunterston, but will include many novel features, particularly with regard to structural and control considerations It will take approximately four years to build and is expected to be in operation by mid-1963 Other articles in the issue include a description of the General Electric Company's atomic energy division by K J Wootton, manager of the division , a discussion of the first sixteen months civil engineering construction at Hunterston by F W Evans , examples of corrosion problems in gas-cooled reactors by M W Davies , and an account of two methods of reducing the permeability of reactor-quality graphite by D A Boyland

Technical Books

THE Atomic Energy Commission of the United States has issued a catalogue of 86 technical books published by the Commission, 1947–59 (Technical Information Service Technical Books sponsored by the U S Atomic Energy Commission Pp 40 Washington, D C United States Atomic Energy Commission, 1959) The list is arranged by subjects and the contents of each volume are indicated The second part of the catalogue similarly lists 26 books in the press or in preparation on April 1, 1959

Nutrition Meeting

THE Nutrition Meeting for Europe of the Food and Agriculture Organization of the United Nations at Rome, June 23–28, of which the report has now been published (Report Series No 21 Report of the Food and Agriculture Organization Nutrition Meeting in Europe, Rome, Italy, 23–28 June 1958 Pp ix+28 Rome Food and Agriculture Organization of the United Nations , London H M Stationery Office, 1958 , 2*s* 6*d* , 0 50 dollar), was concerned with food consumption with special reference to fat consumption and with education and training in nutrition. With regard to the first, the meeting recommended the Organization to take all possible steps to foster improvements in the techniques of food consumption surveys, and of the reporting and analysis of their results, so as to ensure their maximum utility It also recommended periodical meetings of European nutrition workers and that an expert committee or study group, in co-operation with the World Health Organization, should consider the problem of fat consumption and coronary disease in European and other countries The need for further extensive studies of the fatty acid content of foods is emphasized in the report and also of further research to establish satisfactory tables for fatty acid composition The present situation was reviewed with respect to education and training in nutrition, stressing the lack of suitably trained teaching staff The contact between competent research groups, educational authorities and teachers was also considered Further, reference was made to the narrow and unbalanced approach in teaching nutrition and the absence of refresher courses for teachers dealing exclusively or incidentally with nutrition The meeting strongly supported the plea for a seminar in 1959 to study these questions in greater detail and to suggest better practical approaches The main purpose of the seminar would be to examine the scope and effectiveness of education and training in nutrition in Europe It would also formulate proposals for developing and orientating such training by government departments and other agencies, and to promote co-operation and co-ordination between the disciplines and agencies concerned and between those engaged in training and research The report outlines an agenda for a seminar of 12–14 days for 50 to 60 people

Central African Scientific Research

A FURTHER 105 papers published in 1957 by members of the staff and research workers associated with the Institute for Scientific Research in Central Africa are listed in the second part of the tenth annual report of the Institute, making a total of 792 Brief abstracts of these papers constitute the rest of this part of the report (Institut pour la Recherche Scientifique en Afrique Centrale Dixième Rapport Annuel, 1957 Pp 228 Bruxelles Institut pour la Recherche Scientifique en Afrique Centrale, 1959) In the administrative report, which is illustrated, the director, Prof L van den Berghe, indicates briefly the general character of the scientific work of the Institute during the year Prof van den Berghe continued his own study of the biology of the tsetse flies of Bugesera and Mimuli (Ruanda) and at Jiangi, and also on the sexual and asexual cycles of *Plasmodium atheruri* Other work was concerned with the isolation of factors of growth of trypanosomes, and a histopathological study of the hypophysis of small African mammals In nutrition, besides an extensive study of maternal milk and the variation of its content of amino-acids and proteins as a function of the period of lactation, the nutritional value of native beers was also investigated in the region of Lake Kivu and Ruanda-Urundi and the experimental kwashiorkor of swine was studied An investigation of the fauna of the Belgian Congo and Ruanda-Urundi was launched and also of the methods and seasons of reproduction of the birds of Tshibati In physical anthropology a study of the growth of Africans in Ruanda-Urundi was initiated and besides an inquiry into the rural economy of Ruanda-Urundi, one was commenced into the low birth-rate of the people of the Mongo tribe In the physical sciences observations of solar radiation and of the radio-electric activity of the Sun continued, as well as studies of the functional efficiency of dwelling houses at Bagira, Kabunambo and Usumba

International Council of Scientific Unions

The Yearbook of the International Council of Scientific Unions, 1959 (Pp 77 The Hague International Council of Scientific Unions, 1959), provides a comprehensive reference work on the unions Besides lists of members of the Executive Board, national members of the Council, of countries adhering to the Union, and of officers of the International Scientific Unions, it gives the membership of the Special Committees and other organs of the International Council There is also an alphabetical list of these officers and members, the Statutes and Rules of the Council, the text of the agreement between the International Council and the United Nations Educational, Scientific and Cultural Organization and the reports for 1957–58 of the Secretary-General of the International Council The Commissions of the Unions are also detailed and there is a calendar of arrangements for 1959

No 2 of Volume 1 (1959) of the *International Council of Scientific Unions Review* includes D L V Berkner's presidential address to the eighth General Assembly of the Council It also includes the remarks of Sir Harold Spencer Jones, the secretary general, on some affairs of the Council and the reports of the Special Committees for the International Geophysical Year, for Oceanographic Research and for Antarctic Research The constitution of the Committee on Contamination by Extra-Terrestrial Exploration and of the Committee on Space Research is recorded and the report of the former committee is also given This Committee believes that there is a real danger that exploration attempts made within the next few years may produce contamination of extra-terrestrial bodies, which would complicate or render impossible more detailed studies when the technological problems of landing sensitive scientific instruments on the Moon and planets have been solved It recommends that a specific code of conduct representing a reasonable compromise between the early initiation of lunar and planetary exploration and the need to safeguard future research should be drafted with the minimum of delay

Council for the Preservation of Rural England

The twenty-eighth annual report of the executive of the Sheffield and Peak District Branch of the Council for the Preservation of Rural England for the year 1959 (Pp 28 Sheffield Council for the Preservation of Rural England, Sheffield and Peak District Branch, 1959) is seriously concerned as to the preservation of the National Parks It emphasizes the importance of public opinion exerting effective pressure through such bodies as the Council for the Preservation of Rural England if the Peak District National Park, and other national parks, are not to be seriously damaged At the present time the executive is seeking to prevent the desecration of the Manifold valley by a motor road and is opposing a major attack on the Green Belt of the Sheffield Development Plan—at Middlewood in the Don valley With the local authorities and others the Branch vigorously opposed the proposals to prospect for opencast coal in the Troway valley, but the recent Government statement that areas of natural beauty will no longer be marred for this purpose should put an end to prospecting in this area It is pointed out, however, that absence of national funds prevented the Peak Park Branch from petitioning against the Waterworks Bill which proposes to submerge the Oler valley, one of the few remaining valleys leading to the heights of the Peak District National Park

Society of Environmental Engineers

A Society of Environmental Engineers has been formed to provide a forum, by meetings, publications and visits, for the exchange of information and views among those engineers who are concerned with the development of equipment to withstand shock, vibration and other forms of environmental conditions, and who carry out research in these fields The first meeting was held in London on May 29 Some fifty members and guests attended and papers reviewing the field of work were presented by Mr D A Nutt (Armstrong Whitworth Aircraft, Ltd), Mr F I L Knowles (Ministry of Supply) and Dr P Grootenhuis (Imperial College of Science and Technology) Future meetings are to be on November 25 and February 17 at the Imperial College The first annual general meeting of the Society will be held on March 30 at the Royal Society of Arts Further information can be obtained from the Secretary, Society of Environmental Engineers, 42 Manchester Street, London, W 1

Progress of Chemical Engineering

In the presidential address to the Institution of Chemical Engineers on April 28, Sir Hugh Beaver discussed the development and progress of chemical engineering in Britain, particularly in comparison with other countries Pointing out that chemical engineering was now acknowledged as the fourth great technology, Sir Hugh thought that the Zuckerman Committee's estimate of our requirements of chemical engineers was too low The figure of about 4,400 was below the present membership of the Institution—5,900 in 1959, and recent calculations of membership put the figure for 1965 at 8,800 and for 1967 at 11,100 Although the rate of increase had changed greatly in the past eight years, only in the past two or three had it approached the rate of increase in the United States All these calculations, however, involved a change of attitude and policy as well as of methods in British industry as would enable industry to absorb these numbers, and Sir Hugh regarded the increased application of chemical engineering as a measure of the use of modern techniques of manufacture Referring to the training of the chemical engineer, Sir Hugh favoured our system of three, or at most four, years college education followed by practical training He also said that the works training must be scientific and methodical, carefully thought out and systematically applied, and the system of education, while avoiding the specialization of the Continent, must produce a sufficient proportion of research students None of the industrialists he consulted had any doubts as to the need for a broad-based training, but Sir Hugh stressed the need for an open mind on this subject With regard to research, he felt that much more should be sponsored, especially industry Further, liaison between industry and university was essential for our national progress

Haida Carvers

A DEPOSIT of the hard, dark shale called argillite was discovered in the Queen Charlotte Islands in the 1820's, and Haida Indian carvers soon began to exploit it as a material for a variety of objects, which they sold as curios This has continued to the present day Many of the objects are miniature copies of the larger carvings in wood, especially totem poles and chests, but tobacco pipes, bowls and plates were often made and are common in museum collections There are also rarer objects, such as flutes

Prof Marius Barbeau is well known for his work on the North-West Coast Indians, and has recently published another of his many monographs on the subject (Canada Department of Northern Affairs and National Resources National Museum of Canada Bulletin No 139 "Haida Carvers in Argillite" By Marius Barbeau Pp viii+214 Ottawa Queen's Printer, 1957 3 dollars) It is a sequel to his previous book, "Haida Myths illustrated in Argillite Carvings", and it deals, as its title implies, chiefly with the carvers themselves, but it is a complete work in itself It is packed with information, but is somewhat haphazardly arranged There are numerous illustrations but no list of them, and there is a table of contents but no index, the nature of the material puts difficulties in the way of providing an adequate index, but the book would have been easier if a list of the objects illustrated had been given, grouped according to their present location A brief account of the carvers at the village of Skidegate is followed by five sections, each dealing with a particular type of object, and the remainder consists of notes on individual carvers The book is full of interest, and the carvers, many of whom the author has known personally, live again under his hand There has been a tendency to deprecate these argillite carvings, on the ground that they were mostly made for sale and hence were a product of acculturation and not truly indigenous Prof Barbeau has done a great service in directing attention to their value as works of art in their own right, made by skilled carvers who not only worked faithfully in their own traditions, but were also capable on occasion of representing extraneous objects in their own style

New Floristic Studies

ATTENTION may be directed to two new and considerable floristic studies C Schweinfurth has added a further contribution on the "Orchids of Peru" (published in *Fieldiana Botany*, 30, No 2; Chicago Natural History Museum, March 1959, 4 dollars 50 cents) The work is in the usual format for this series, and is mainly devoted to two considerable genera, namely *Pleurothallis* and *Epidendrum* Ten other genera with a smaller number of species are also considered All the available information has been used in preparing this volume, though some of the records are understandably still rather scanty The publication is well illustrated by line drawings

J P M Brenan has made a further contribution to the "Flora of Tropical East Africa", the portion now published dealing with Leguminosae subfamily Mimosoideae (publ Crown Agents for Oversea Governments and Administrations, London, May, 1959, price 12*s*) The main features of the subfamily are set out together with a bibliographical commentary and there is an analytical key to the genera based on vegetative and fruit characters, there are also analytical keys to the species within individual genera The text contains much useful descriptive matter dealing with distribution, habitat, etc, and is illustrated by line drawings

Royal Commission for the Exhibition of 1851

THE following awards have been made for 1959 *Senior Studentships* D W Barnes (University of Oxford) for research in pure mathematics at Tubingen, P J Goodford (University of Oxford) for research in pharmacology at Oxford, A V Grimstone (University of Cambridge) for research in zoology at Cambridge, D O Hayward (Imperial College of Science and Technology) for research in physical chemistry at the Imperial College of Science and Technology, M Wells (University of Cambridge) for research in physics at Cambridge The Senior Studentships are of the value of £800–£900 a year and tenable ordinarily for two years *Overseas Scholarships* G F O Langstroth (Dalhousie University) for research in physics at University College, London, A J McComb (University of Melbourne) for research in plant physiology at King's College, London, J W White (University of Sydney) for research in physical chemistry at Oxford, Miss S G Page (University of New Zealand) for research in biophysics at University College, London, A Chisholm (University of New Zealand) for research in physics at Liverpool, M H Proctor (Trinity College, Dublin) for research in biochemistry at Cambridge, A J Ganguly (University of Delhi) for research in organic chemistry at the Imperial College of Science and Technology, London, M Jameel (University of Karachi) for research in physics at Cambridge The Overseas Scholarships are of the value of £550–£650 a year and tenable for two or three years

American Academy of Arts and Sciences Foreign Honorary Members

THE American Academy of Arts and Sciences, at its 179th annual meeting on May 13, in Boston, elected 113 new Fellows from the United States, and 21 new Foreign Honorary Members as follows: Sir John Eccles, Australian National University, Canberra, Jean Brachet, Université libre de Bruxelles, Georges Braque, Paris, Albert Camus, Paris, Jean Leray, Collège de France, Paris, Max Born, Bad Pyrmont, Germany, George Keith Batchelor, Cambridge, Sir Isaiah Berlin, Oxford, Sir Lawrence Bragg, Royal Institution, London, Frank C Francis, British Museum, London, Anna

Freud, London, David Keilin, Cambridge, P B Medawar, University College, London, Sir George White Pickering, Oxford, Ronald Syme, Oxford, Federico Chabod, Croce Institute, Naples, Hitoshi Kihara, National Institute of Genetics, Misima, Carlos Chavez, Mexico City, M. G J Minnaert, University of Utrecht, Alf A Sommerfelt, University of Oslo, A N Kolmogorov, Academy of Sciences, Moscow

At the same meeting Dr Kirtley F Mather, emeritus professor of geology, Harvard University, was re-elected president for another year

University News.

Bristol

The following appointments have been made Dr J T Martin to a readership in chemistry of insecticides and fungicides Lectureships have been conferred on Dr E W Abel (inorganic chemistry), Dr R F Burbridge (electrical engineering) and R H. C Penny (chemical pathology, veterinary)

University College, Dublin

Dr A L Kapoor of the National Chemical Laboratory, Poona, has been appointed an I C I Fellow in Chemistry at University College, Dublin

Liverpool

The following appointments have been made to take effect from October 1 Dr B Collinge, reader in physics, Dr P M Sheppard, reader in genetics The following have been appointed to senior lectureships Dr A. K Holliday, inorganic and physical chemistry, Dr N S Jones, marine biology, Dr T M Flett, pure mathematics, Dr A Ashmore, physics; Dr H D Parbrook, physics-acoustics, Dr V H Leck, electronic engineering, Dr R S Benson and Dr N G Calvert, mechanical engineering, Dr F T W. Jordan, veterinary preventive medicine

University College of North Staffordshire

Dr D J E Ingram, at present reader in electronics in the University of Southampton, has been appointed professor of physics, to take effect from October 1

Nottingham

The following appointments have been made to take effect from October 1 Dr K J Standley, to a readership in physics, Dr G E Lamming, to a readership in animal physiology, Dr M Woodbine, to a readership in agricultural microbiology

Sheffield

The following appointments have been announced Dr D E Bourne, lecturer in applied mathematics, Dr R S Duff, senior lecturer in medicine, I E Gillespie, lecturer in surgery, D W Warrell, lecturer in obstetrics and gynaecology, L Grimshaw, lecturer in psychiatry

Swansea

Prof F Llewellyn Jones, professor of physics, University College of Swansea, has been appointed acting principal of the College until such time as a new principal takes office

Announcements

Dr P T Haskell has been appointed deputy director of the Anti-Locust Research Centre, London, in succession to Dr T H C Taylor, who became director on the retirement recently of Dr B P Uvarov (see *Nature*, 183, 1160, 1959) Dr Haskell has been at the Centre since 1955, and was previously lecturer in entomology in the Imperial College of Science and Technology, London Most of his published work has been concerned with sensory physiology, especially the production and perception of sound in insects

Dr Carl F Kossack, formerly head of the Department of Mathematics and Statistics at Purdue University, has joined the research organization of the International Business Machines Corporation at the Lamb Estate Research Center in the Town of Cortlandt, New York Dr Kossack is manager of the newly formed Statistics and Operations Research Department Dr Kossack gained his B A and M S degrees in mathematics at the University of California and his Ph D degree in mathematical statistics from the University of Michigan

A joint meeting of the Challenger Society and representatives from the marine laboratories (Development Commissioners' scheme) will be held at the Guildhall, Conway, North Wales, on October 28 and 29 Further particulars of the meeting can be obtained from Dr H O Bull, Dove Marine Laboratory, Cullercoats, Northumberland

The U S S R Academy of Sciences began to publish in the Russian language in 1959 the following new journals (in brackets, the first figure indicates number of issues per annum, the second figure, the price in roubles per annum) *High Molecular Compounds* (12, 150), *The Geology of Ore Deposits* (6, 72), *Palæontological Journal* (4, 60); *Radiochemistry* (6, 72), *The Physics of the Solid Body* (12, 150), *Cytology* (6, 72), *Soviet Slavic Studies* (4, 50)

The Commonwealth Scientific and Industrial Research Organization of Australia has issued a pamphlet listing the Organization's Divisions and Sections, as at January 1, 1959, giving the address of each and its laboratories, and the names of the Officers-in-Charge State Committees are also listed Publications of the Organization, to December 31, 1958, including those of its predecessors, are listed in a separate pamphlet

Volume XV of the Collected Papers of the Rowett Research Institute (Bucksburn Rowett Research Institute, 1959) contains an account of work of the Institute, lists of members of its governing body and scientific staff and of 88 published papers, reprints of most of which are available, as well as a summary, by the Director of the Institute, of the contents of published papers of the Institute 1957–58 so arranged as to indicate the scope, continuity and integration of the research programme Two subject reviews are also included by J J Bullen on experimental reproduction of enterotoxæmia of sheep and by J Duckworth on Institute research on the skeleton in lactation and growth

The Department of Scientific and Industrial Research will shortly resume publication of its *Technical Digests*, last issued in 1957 Their object is to direct attention to useful ideas appearing in technical literature, and following an initial free distribution to industrial firms they will be available at an annual subscription of £3 3*s* A reduction will be offered for supplies in quantity The digests will be published monthly, each being printed on a separate sheet of paper

THE TWO CULTURES AND THE SCIENTIFIC REVOLUTION

SIR CHARLES P SNOW'S Rede Lecture* for 1959 carries forward to a significant extent the old arguments concerning those subjects commonly spoken of as the humanities on one hand and the sciences on the other The teaching of the history and sociology of science to arts students and the teaching of the history of art and literature to science students is better than nothing, though it is difficult to see how the history of science can make much impact without a knowledge of the methods and results of scientific investigation The corpus of knowledge of all types is now so vast that it is foolish to look back to a Hellenic or Thomistic attempt at a synthesis

Sir Charles Snow is both a literary man and a scientist and is able to see each side of the problem from the other He seems to find the smug, self-contentment of many of the literary men more dangerous and irritating than the failure of some scientists to realize the implications of their own work in the broader field of human knowledge and aspiration "Why do most writers take on social opinions which would have been thought distinctly uncivilized and démodé at the time of the Plantagenets ? Wasn't that true of most of the famous twentieth-century writers ? Yeats, Pound, Wyndham Lewis, nine out of ten of those who have dominated literary sensibility in our time—were they not only politically silly, but politically wicked ? Didn't the influence of all they represent bring Auschwitz that much nearer ?"

But it is ill-considered of scientists to judge writers on the evidence of the period 1914–50 Literature changes more slowly than science It has not the same automatic corrective and so its misguided periods are longer

"At one pole, the scientific culture really is a culture, not only in an intellectual but also in an anthropological sense Its members need not always completely understand each other—biologists more often than not will have a pretty hazy idea of contemporary physics—but there are common attitudes, common standards and patterns of behaviour, common approaches and assumptions This goes surprisingly wide and deep It cuts across other mental patterns, such as those of religion or politics or class In their working, and in much of their emotional life, their attitudes are closer to other scientists who in religion or politics or class have the same labels as themselves At the other pole, the spread of attitudes is wider It is obvious that between the two, as one moves through intellectual society from the physicists to the literary intellectuals, there are all kinds of tones of feeling on the way But I believe the pole of total incomprehension of science radiates its influence on all the rest That total incomprehension gives, much more pervasively than we realize, living in it, an unscientific flavour to the whole 'traditional' culture, and that unscientific flavour is often, much more than we admit, on the point of turning anti-scientific Once or twice I have been provoked (by the 'non-scientists') and have asked the company how many of them could describe the Second Law of Thermodynamics The response was cold it was also negative Yet I was asking something which is the scientific equivalent of Have you read any work of Shakespeare's ?"

Little purpose is served by cataloguing the dismal ignorances in many arts people of the simplest, fundamental principles of science "The separation between the scientists and non-scientists is much less bridgeable among the young than it was thirty years ago , then they managed a kind of frozen smile across the gulf Now the politeness has gone and they just make faces It is not only that the young scientists now feel that they are a part of a culture on the rise while the other is in retreat It is also, to be brutal, that the young scientists know that with an indifferent degree they will get a comfortable job while their contemporaries and counterparts in English or History will be lucky to earn 60 per cent as much No young scientist of any talent would feel that he is not wanted or that his work is ridiculous as did the hero of Lucky Jim , and in fact some of the disgruntlement of Amis and his associates is the disgruntlement of the under-employed arts graduates "

Sir Charles insists that we should completely re-think our education "Nearly everyone will agree that our school education is too specialized But nearly everyone feels that it is outside the will of man to alter it Other countries are as dissatisfied with their education as we are, but are not so resigned Because of our intense specialization, alleged by schoolmasters to be dictated by the Oxford and Cambridge Scholarship examinations, we have set ourselves the task of producing a tiny élite—far smaller proportionately than in any comparable country—educated in one academic skill " Snow takes as an example the old Cambridge Tripos which seemed to be perfect in all respects save one The one exception was—so the young creative mathematicians, such as Hardy and Littlewood, kept saying —that the training has no intellectual merit at all They went a little further and said that the Tripos had killed serious mathematics in England stone dead for a hundred years

While we are beginning, after many years, to understand the scientific and social implications of the industrial revolution and to understand the development in teaching technology in Germany in the nineteenth century and in the United States and U S S R in later years, we are still far from grasping the meaning of the scientific revolution, by which is meant the transformations made in industry and its effects because of electronics, atomic energy, automation and modern forms of machine tools

We have failed to keep pace with the new scientific revolution—"roughly if we compare like with like and put scientists and engineers together we are training at a professional level per head of the population one Englishman to every one and a half Americans to every two and a half Russians In Russia the gap between the cultures does not seem to be as wide as it is with us If one reads contemporary Soviet novels, for example, one finds that their novelists can assume in their readers—as we cannot

---

* Published by the Cambridge University Press

—at least a rudimentary acquaintance with what industry is all about' The latest figures of graduates trained per year (scientists and engineers combined) are roughly United Kingdom, 13,000 , United States, 65,000 , U S S R , 130,000 One-third of Russian graduates in engineering are women "It is one of our major follies that we do not in reality regard women as suitable for scientific careers We thus divide our pool of potential talent by two "

"We are left with a population twice as large as we can grow food for, so that we are always going to be *au fond* more anxious than France or Sweden, and with very little in the way of natural resources—by the standard of the great world powers, with nothing The only real assets we have, in fact, are our wits Those have served us pretty well, in two ways We have a good deal of cunning, native or acquired, in the arts of getting on among ourselves that is a strength, and we have been inventive and creative, possibly out of proportion to our numbers Given these two assets, and they are our only ones, it should have been for us to understand the scientific revolution first, to educate ourselves to the limit and give a lead In some fields, like atomic energy, we have done better than anyone could have predicted Within the pattern, the rigid and crystallized pattern of our education and of the two cultures, we have been trying moderately hard to adjust ourselves The historical warnings are all there For instance, the Venetian Republic in its last half-century was guided by patriot men, who had immense political skill, who knew that the current of history had begun to flow against them They were fond of the comfortable pattern of their life, just as we are fond of ours They never found the will to break it "

There is yet another danger The large masses of poor in the undeveloped countries will not allow themselves to live for ever in a world in which large sections have become rich through industry A new missionary spirit, both human and technical, is essential

"Closing the gap between our cultures is a necessity in the most abstract intellectual sense, as well as in the most practical When those two senses have grown apart, then no society is going to be able to think with wisdom For the sake of the intellectual life, for the sake of this country's special danger, for the sake of the western society living precariously rich among the poor, for the sake of the poor who need not be poor if there is intelligence in the world, it is obligatory for us and the Americans and the whole West to look at our education with fresh eyes This is one of the cases where we and the Americans have the most to learn from each other We have each a good deal to learn from the Russians, if we are not too proud Incidentally, the Russians have a good deal to learn from us too " W L SUMNER

COAL SCIENCE

THE third biennial International Conference on Coal Science was held at Valkenburg, in the Netherlands, during April 27–30 The Municipality kindly allowed the Conference to be held in the Municipal Theatre, and the greatest hospitality and interest were shown throughout by the burgomaster, F A A H Breekpot

On this occasion the number of participating countries increased to fourteen, newcomers being East Germany, Czechoslovakia, Australia and India Authors submitting papers were required to complete a form indicating, in telegraphic style, their main new conclusions and results, the methods and observations from which these were deduced, and any special limitations or assumptions involved in their interpretation This information was found by the organizers to be more helpful than the conventional summary (or on occasions the paper itself) in deciding whether a paper was acceptable , it was also useful in evaluating the conclusions of the Conference and the interrelation of papers The proceedings of this Conference will not be published as a whole , but papers will be submitted by their authors to journals of their own choosing

Discussion was unusually lively and fruitful, and a large proportion of novel work was presented In several cases widely accepted ideas were apparently undermined, though it would be premature to assess the importance of the new evidence For example a suggestion arose, from the work of S Ergun and I Wender on the X-ray scattering of vitrinites reduced with lithium in ethylene diamine, that partially reduced aromatic and/or alicyclic molecules may lead to reflexions in the angular region where the (10) and (11) reflexions of aromatic molecules occur This awaits direct experimental test, but if correct it may throw doubt upon the derivation of aromatic layer sizes in coal, for example, by Hirsch and Diamond Ergun and Wender also demonstrated an increase of layer-spacing on reduction, even in graphite

Similarly, an interpretation of data obtained on coal by high-resolution magnetic resonance spectroscopy, by J K Brown W R Ladner and N Sheppard, yielded a structural distribution of non-aromatic carbon atoms which may prove incompatible with the present consensus of opinion on the chemical structure of coal As a third example, R L Bond and D H T Spencer illustrated the inadequacy of existing interpretations of sorption data obtained with inert gases on coal and of heats of wetting of coal in polar liquids , a question thought by many to have been settled, at least in principle

These, and the other thirty-three papers presented, were grouped under four heads, as follows

Chemical Reactions of Coal

E S Hammack, H G Davis and F B Brown estimated the content of phenolic hydroxyl in vitrains by titration with sodium aminoethoxide in ethylene diamine, by trimethylsylylation and by acetylation They found reasonable agreement between these methods and noted the importance of particle size Acetylation was studied by S Delavarenne, A. Halleux and H Tschamler, who also confirmed the presence of quinone groups in coal extracts, by reductive acetylation and reduction with copper/hydrogen sulphide They observed the corresponding changes in the infra-red spectra and showed that the reduction was to a large extent reversible In both papers, tests of the quantitative accuracy of the methods by experiments on model compounds such as quinones were reported Evidence for the presence of thioether groups in coals to the extent of 15–90 per cent of the organic sulphur content was put forward by L Wnękowska The difficulty of combining all known observations on the chemical and physical nature of coal, together with the elementary analysis, in a structural model was emphasized by P H Given, who by comparison of data and experiments with atomic models had been able to find only one satisfactory pattern of structure the essential feature of this was that any pair of aromatic fused ring clusters is bound together by *two* methylene bridges

E J Greenhow and J W Smith showed that pitch can be regarded as a solution of phenolic or basic compounds of medium molecular weight in a relatively non-polar solvent , results suggested that the physical properties were influenced by intermolecular association

There were three papers on chromatographic separation of oxidation products of coal by F Micheel, J E Germain and F Valadon, and G J Lawson and S G Ward The first author had isolated small yields of aniline, anthracene, substituted anthraquinone, tetraphene and fluoranthene from air- or nitric acid-oxidized coals , the second group had identified various benzene polycarboxylic acids, and the third, malonic, succinic and *l*-tartaric acids S Landa had studied hydrogenation of model substances, montan wax and humic acids extracted from brown-coal, with tungsten and molybdenum sulphide catalysts Hydrocarbons with two to three fused aromatic rings and side-chains were found among the products from treatment of the humic acids

Ultra-fine Structure of Coals and Chars

M Węclewska discussed the influence of sorption on coals of organic vapours on their elasticity, and the consequent dimensional changes S Ergun, W F Donaldson and I Breger showed that apparent changes in rank induced in coals by α-particles originating from natural impregnation by uranium differed from those caused by normal coalification processes

J L Soulé and S Durif demonstrated, by measurements of small-angle X-ray scattering, the presence in a wide range of coals of pores of sizes 22–25 A and the variation of this characteristic with temperature of carbonization , they also deduced absolute values of specific internal surface In the carbonization temperature range 500–700° C these surface areas agreed with those estimated by P Chiche and S Prégermain from adsorption of water and methanol vapours

Sorption of pyridine by carbonization products, their solubility in it and their swelling in various organic liquids, were studied by A Ladam and P Payen Important changes were indicated in the region 400–500° C S J Gregg and M I Pope had studied the effect, on the electrical conductivity of coal artefacts, of pressure and of exposure to atmospheres of various humidities J J Kipling and R B Wilson, from a study of the sorption of gases and vapours on chars prepared by carbonizing synthetic polymers, demonstrated the presence of microcapillaries of 5–10 A diameter, molecular sieve properties of the structure, and the effect of steam activation in opening up this structure A Cameron and W O Stacey combined measurements of internal surface area, apparent density and measurement of internal volume with the porosimeter to demonstrate the presence of two distinct pore systems in chars prepared from brown-coals The presence in 600–900° C chars of cavities of some 25 A linked by passages less than 10 A wide was inferred

Spectroscopy of Coals

There were two papers on mass spectroscopy One, by J C Robb and H W Holden, was concerned with the volatile products either volatilized or liberated by pyrolysis when coal was heated in the ion source Interesting identifications in relation to temperature range were made The other, by R I Reed and W Snedden, was chiefly concerned with the fragments produced from aromatic compounds and thus widened the background available for interpreting results with coals Electron magnetic resonance spectroscopy had been used to study coals in course of carbonization under vacuum, by J Smidt and D W van Krevelen In addition, the time of relaxation T_1 was measured as a function of temperature J Uebersfeld had applied combined nuclear and electron magnetic resonance measurements and found evidence of interaction between protons and free radicals in coals of low rank, exchange interaction in those of high rank Light spectroscopy was represented in two papers, by R A Durie and J Szewczyk and by S Ergun and J T MacCartney The first was concerned with a long wave-length absorption edge which moves into the infra-red with increasing temperature of pyrolysis The magnitude of a corresponding energy gap in the structure was discussed in relation to the graph of polynuclear aromatic structures In the other paper an attempt was made to establish specific reflectance of coals as a significant structural parameter, related to the hydrogen/carbon ratio and to the diamond and graphite structures as extremes

Carbonization

C Kroger, R Brucker, M Klatt and E Bade had studied the maceral species exinite and vitrinite by pyrolysis under high vacuum They discussed the origin of the liquid and gaseous products determined A M Wandless and G W Fenton described coking tests, on coals of 84, 85 and 87 per cent carbon content, that indicated a beneficial effect on the coke strength of the maceral inertinite as a constituent in the coal blend at the two lower levels of rank D W van Krevelen, F J Huntjens and A H Wilms presented a thorough study of strength of coke in relation to particle size of coal carbonized A D Dainton, W G Kaye and J W Phillips described the effect of macerals on volume changes in briquettes during carbonization A F Boyer and P Payen threw doubt on the interpretation of an apparent exothermic peak found in the differential thermal analysis of certain coals , they considered this to result from an increase of conductivity due to agglutination Finally in this series there was an outstanding paper by P M J Wolfs, D W van Krevelen and H I Waterman on the carbonization of synthetic polymers containing aromatic units linked by methylene bridges labelled with radioactive carbon , their fate on pyrolysis could be readily followed The course of chemical decomposition was thus related to other measurements on the polymer, for example, in a dilatometer test and a thermobalance

M. F. Kessler and V. Večeřikova reported a variety of physical and physicochemical measurements on cokes and related them to hardness and reactivity. J. H. Ehretsmann and R. C. Seymour had studied the gaseous products and thermochemistry of the formation and decomposition of surface oxides on charcoals. H. Guérin and M. Bastick demonstrated the importance of microporosity during gasification of coke between 800° and 1,000° C. C. Heuchamps, L. Bonnetain, X. Duval and M. Letort showed that the apparent energy of activation of the combustion of graphite varied with temperature and extent of combustion, and was a complex function of heterogeneity, porous structure, impurities and reaction mechanism.

It is appropriate after three successive occasions when the burden of organization has largely been borne by the Dutch State Mines to add an appreciation of the magnificent arrangements made by the scientific and administrative staff of that body. The never failing resourcefulness of Mr. W. J. R. Berkx in all aspects is especially worthy of mention. The moving spirit behind these conferences has been the president, Prof. D. W. van Krevelen, and it must be recorded with regret that he has now resigned the presidency in view of his pending transfer from the coal to the plastics industry. To mark the occasion, tributes were paid at the end of the Conference by R. Loison, I. G. C. Dryden and M.-Th. Mackowsky on behalf of the French-, English- and German-speaking sections of the audience. Prof. van Krevelen's impact on coal science has occurred only within the past ten years; yet, owing to the original and prodigious output of his research teams, he has left nothing unchanged. The Conference wished him every success in his new field of endeavour.

I. G. C. DRYDEN

CURRENT RESEARCH ON NOISE

It is only within recent years that acoustic noise, once studied simply for its effect on hearing and annoyance, has proved important in physical systems. Noise has long been a source of annoyance; its effects on working efficiency have been clear when it has interfered with speech communication, less clear in causing fatigue; and for years it has been realized that continued excessive noise can cause permanent deterioration of hearing—'boilermaker's deafness' has long been known.

These effects are still with us, in intensified form, since with the increased power of machines to-day, noise—as a by-product of this power—is increasing also. For this reason, the physical aspects of noise have come to the fore. The intense fluctuating pressures in the noise field near a jet engine can fatigue and fracture the structure of the aircraft. The forces on a missile flying through rough air may consist largely of random constituents, which need to be analysed in some detail to determine whether any frequencies are present which may damage the equipment in the missile. Such analysis is, of course, similar to that used in many other fields, such as radar; and thus acoustic noise problems find their counterparts in other studies.

These different aspects of noise were explored recently in two symposia held by the Acoustics Group of the Physical Society. The first, "Recent Studies of Noise Problems", was held at the Imperial College of Science and Technology, London, on March 24, with four papers on psycho-acoustic problems, and two on physical acoustics.

Human Response to Noise

The general effect of the first group of papers, curiously, was that work in many aspects of the subject culminated some five years ago in the United States, and little advance has been made since. This was particularly true of the account of noise and hearing loss given by Prof. W. Burns (Charing Cross Hospital Medical School). This subject is still heavily in debt to the classic report (*Z24-X-2*) of the American Standards Association, and little more has been learnt about safe noise-levels. However, work is continuing on the effect of age on normal hearing; this will give a better 'base-line' for the estimation of hearing damage, and is a subject on which the American report was not very satisfactory.

Procedures for evaluation of the loudness of a complex sound, however, have progressed very little in any country. This was discussed by Mr. N. Fleming and Mr. D. W. Robinson (National Physical Laboratory). The National Physical Laboratory equal-loudness contours remain unchallenged, but they are for pure tones only. The various ways of dividing and weighting the spectrum, in order to calculate loudness, do not seem very productive; while annoyance is a factor even harder to measure objectively.

Much of this difficulty may be due to the fact that pure tones have in the past been considered of major importance. But as speech, and even music, are in effect successions of transients, many noises should be considered in the same way; and a study of the aural effects of transients may be a more fruitful approach.

The point was, however, made by Mr. Fleming that the multiplicity of criteria in American psycho-acoustic studies may not be needed. He pointed out the equivalence between the 'equal-annoyance' contours for community noise, and the readings of representative noises on the *A* weighting of the sound-level meter. The *A* weighting is a valuable one for many approximate loudness studies; it is frequently used on the European continent in traffic-noise problems.

Further points on community reaction to noise were dealt with by Mr. H. J. Purkis (Building Research Station). The techniques for evaluating the annoyance of different types of noise, developed in America some years ago, still appear generally valid, although some alterations to suit the differing susceptibilities of English communities are needed. It is hoped to collate several case histories of noise annoyance, with the view of obtaining more applicable data.

Dr. D. E. Broadbent (Medical Research Council) spoke on the effects of noise on working efficiency. This is a field in which it is most difficult to obtain conclusive results. A pattern is, however, beginning to emerge, connected with the effect of noise in interrupting attention; noise often seems to interfere with tasks necessitating short-term memory. An overall level of 90 db. appears critical, and it is found that, whatever may be the effect on efficiency at work, noise increases, for example, wastage rate, and number of mistakes

Physical Acoustics

Two papers on physical noise problems were presented Mr D M A Mercer (University of Southampton) dealt with the difficulties inherent in obtaining accurate measurements of aircraft noise Such factors as ground reflexions, size and behaviour of source can cause errors of a few decibels , comparisons of, for example, the performance of jet silencing devices may be quite misleading if these precautions are not taken

Diesel engine noise was discussed by Dr A E W Austen and Dr D Priede (C A V , Ltd) Speed and swept volume have been related to sound output , there is little variation with load, due to the characteristics of the diesel engine A quite thorough survey has been made of the vibration of different surfaces of the engine and their effects as noise producers, and sound-levels calculated from these are consistent with measured noise-levels

Aspects of Noise Analysis

The second symposium, on "New Techniques in the Analysis of Noise and Vibration", was held in the Physics Department of the University of Southampton, as a joint meeting with the Institute of Physics The attendance of about 150, drawn from diverse fields of physics, engineering and electronics, indicated the considerable interest in the analysis of 'noise in the widest sense' The emphasis was on new and projected techniques , standard bandpass filtering methods received little attention

The meeting was opened by Mr R A Eades (Signals Research and Development Establishment, Christchurch), who described the speech spectrograph, an instrument capable of examining and analysing short samples of sounds, and presenting the analysis in a manner similar to that of the visible-speech techniques Mr Eades made the important point that, in much of this work, bandpass filters with sharp cut-offs are not desirable, due to the 'ringing' they give , the lowered frequency discrimination of a filter of Gaussian or tuned-circuit characteristics is amply repaid by freedom from ringing

Mr G J Herring (Royal Aircraft Establishment, Farnborough) described an analogue-to-digital converter which converted a fluctuating voltage into an input suitable for a *Pegasus* digital computer The computer could then be used to make an analysis of the input wave-form This method was developed because purely analogue methods had proved unsatisfactory This paper, and the previous one, led to considerable discussion , it was clear that the problem of analysis of random wave-forms was important to many workers One point, however, was that the distinction between wave-forms with and without a periodic component—a difference important to the statistician —was not always made clear , with consequences perhaps of unnecessary difficulties in many analyses

Mr D M A Mercer (University of Southampton) emphasized the practical point that, in any analysis, frequency discrimination, stability of estimates and ease of computing were all linked, and could not all be maximized at once, great care was needed in the planning stages of an analysis Cross-correlation techniques were often able to give results unobtainable by straightforward methods

Dr G M Jenkins (Imperial College of Science and Technology, London) discussed the statistical implications of obtaining a spectrum via an autocorrelogram It is desirable to examine the autocorrelogram itself before the Fourier transform process , in any event, some modification to it is often desirable, to obtain a more stable spectrum, but in addition much information is often available at this stage , and different applicable statistical criteria were described

The ensuing discussion demonstrated much interest in the use of axis-crossings of a random function Presumably there is a major theoretical breakthrough to be looked for on this topic , but apart from this, theoretical and experimental studies demonstrate that axis-crossings carry most of the information of a wave-form (apart from magnitude, of course) The limitations of the method, however, are not yet known

The concluding impression of the symposium appeared to be twofold first, that 'noise in the widest sense' is a subject of considerable interest, and secondly, that there often appeared to be a considerable gap between the theoretical studies, and the work of those concerned with practical noise and vibration analysis This leads, at best, to correct analyses obtained with unnecessary difficulty, and at worst, analyses which are meaningless Closing of this gap would be of benefit to all concerned

DERWENT M A MERCER

BIOSYNTHESIS AND SECRETION OF ADRENOCORTICAL STEROIDS

AT a symposium held on February 14, the Biochemical Society gathered together a group of investigators who described their own work and that of others on various aspects of the biogenesis of the adrenocortical hormones In an introductory paper, I E Bush described the chemical nature of the steroids under discussion and the application of various types of chromatographic procedures to the separation and identification of these substances An important feature of steroid chromatography is the very large number of possible compounds and the danger of wrong identification if chromatographic properties are relied upon to the exclusion of others This danger may be diminished by the use of numerous microchemical and spectrophotometric techniques The former include acetylation or oxidation (notably the removal of the C-17 side chain) on the 10–20 μgm scale, followed by observation of the chromatographic behaviour of the product on paper Spots of steroid on paper give various well-known colour and very sensitive fluorimetric reactions On the physical side a wide range of correlations between structure and absorption bands in the infra-red region has been established Ultra-violet absorption spectra in sulphuric acid and alcoholic alkali provide useful information which, in conjunction with paper chromatography and comparison with reference substances, may provide identifications almost as reliable as those from infra-red spectra New work in Bush's laboratory has shown that useful generalizations about the behaviour of steroids in partition systems can be made using Martin's theory and the R_M function of Bate-Smith and Westall For this theoretical approach Bush has collected numerous R_F values from the literature Not all will agree with him on the reliability of these values The chromatogram tank is not yet a precision instrument

J K Grant then reviewed present knowledge of the biosynthesis of adrenocortical steroids Here there are at least three questions to be answered What is the nature of the secretion of the adrenal cortex, what sequences of reactions are involved in the syntheses of the steroids in the cortical cells and what are the mechanisms of these reactions ? Complete answers cannot be given The analysis of adrenal venous blood collected from animals and from human subjects undergoing adrenalectomy has provided direct evidence of the nature of the steroids secreted by the adrenal gland Hydrocortisone, corticosterone and aldosterone are the principal C_{21} compounds found The last of these, and a variety of others of less physiological importance, are present in trace amounts There is indirect evidence that the adrenal cortex in man secretes a substance which, in contrast with aldosterone, promotes the excretion of sodium A new steroid (3β 16α-dihydroxy-5α-pregnan-20-one), which produces this effect in rats, has recently been isolated by Wettstein from the adrenal glands of swine There is also evidence that the adrenal gland secretes androgenic and œstrogenic steroids

Application of a variety of techniques has clearly established that adrenocortical steroids may be formed in the gland from acetate or cholesterol by formation and subsequent hydroxylation of progesterone An outstanding question of major interest is the possibility of alternative pathways to those originally proposed These alternatives are concerned with the order in which the hydroxylations of the key intermediate progesterone proceed, with the possibility that cholesterol is not an obligatory intermediate in hormone formation, and with the direct transformation of cholesterol to C_{19} steroids Hydroxylations commonly occur at C-17, C-21 and C-11β in that order It has been shown beyond reasonable doubt that a C-21 hydroxy steroid cannot undergo hydroxylation at C-17 Grant has, however, demonstrated that 11β-hydroxylation of progesterone can proceed in good yield Hydrocortisone may then be formed from 11β-hydroxyprogesterone but at rates too slow to be of significance in normal biosynthesis This alternative pathway may, however, be important in pathological states Despite much suggestive evidence and numerous experiments with isotopically labelled compounds, it has not been possible to establish firmly the existence of alternative pathways from acetate to adrenocortical hormones which do not involve cholesterol When such pathways appear to have been demonstrated, alternative explanations of the results have been possible if the existence of different metabolic pools of adrenal cholesterol is assumed In other cases the results are unacceptable since the comparisons between the specific activities of precursors and products have been made at one point in time and not on a kinetic basis known to be essential in order to avoid misinterpretation of results Despite intensive study, the mechanism of steroid hydroxylation has not been elucidated Molecular oxygen and reduced triphosphopyridine nucleotide are essential It has not been possible to confirm that a transhydrogenase is involved in the formation of reduced triphosphopyridine nucleotide It has been suggested that the reduced nucleotide is required for the reduction of an oxygen activating or transferring enzyme containing a heavy metal, but proof is lacking There are, however, indications that the 11β-hydroxylating enzyme system located in the mitochondria is complex The observation that 2-methyl-1 2-bis-(3-pyridyl)-1-propanone (*SU* 4885) appears to be a specific inhibitor of 11β-hydroxylation *in vivo* and *in vitro* has aroused considerable interest

Adrenal glands of the rat, ox and man have been most extensively studied The anatomy and histology of these glands were described by T Symington He directed attention to two features which have not until recently received adequate attention from biochemists the unusual musculature of the adrenal veins which may, by restricting blood flow through the gland, influence steroid biosynthesis, and the marked differences in histology between the ruminant and non-ruminant adrenal cortex The fascicularis and reticularis zones, readily distinguished in non-ruminants, are not distinguished in the ruminant In the ox, which is typical of the ruminants, a broad zone of 'compact' cells fills the cortex from the medulla to the prominent glomerulosa beneath the capsule In man, the fasciculata zone of variable width is filled with lipid-laden 'clear' cells and lies between the reticularis zone of 'compact' cells and the glomerulosa, which is very irregular, forming islands under the capsule so that glomerulosa cells are absent from some sections The ox adrenal gland is for this reason a more satisfactory object than the human gland for the *in vitro* study of the synthesis of aldosterone which appears to occur in glomerulosa cells The morphology and histochemistry of 'clear' and 'compact' cells and the influence of corticotrophin thereon have been studied in Symington's laboratory using glands removed surgically in two stages for the treatment of breast cancer The use of these fresh glands has also permitted the study of enzyme reactions involved in steroid biosynthesis These biochemical studies and in addition the results of analysis of adrenal venous blood obtained at the time of adrenalectomy have been correlated with the morphological and histochemical observations It would appear from the results obtained that 'clear' cells of the fasciculata zone may function as stores of hormone precursor, and that the 'compact' cells of the reticularis zone, far from being the senescent cells described by others, may be the site of active hormone biosynthesis 'Clear' cells are converted to 'compact' cells under the influence of corticotrophin, which stimulates corticosteroid secretion, influencing various steps in the sequence of biosynthetic reactions Studies with the electron microscope in Glasgow have revealed important differences between the 'clear' and 'compact' cells, the most striking features of which are the microvilli, which form extensions of the cell membrane running out into the intercellular spaces The function of the microvilli is unknown, but it is interesting to speculate that they may be concerned with secretory processes

P J Ayres described the relation of steroid secretion to the histological zones of the adrenal cortex, with particular reference to the evidence which he has obtained in collaboration with Dr and Mrs Tait that aldosterone is synthesized and secreted by the cells of the glomerulosa zone. This work developed out of early observations on the rat; these supported the view that a steroid active in electrolyte metabolism was secreted by the glomerulosa zone, relatively independent of the pituitary but influenced by electrolyte intake. Further indirect evidence followed the isolation of the steroid concerned, aldosterone, from whole adrenal extract by the Taits in 1952. It was possible to show that aldosterone secretion, but not that of corticosterone, is diminished in rats on a low-potassium diet. Hypophysectomy has a much more pronounced effect on corticosterone than on aldosterone secretion in the rat. After this operation in dogs, the fasciculata-reticularis zone of the adrenal gland atrophies and the secretion of hydrocortisone and corticosterone falls; by contrast the glomerulosa zone and the secretion of aldosterone are unaffected. Direct evidence for the preferential production of aldosterone in the glomerulosa zone was obtained by the Taits and their collaborators by incubation of adrenal capsule strippings, to which glomerulosa cells were adhering, and of tissue from the underlying zone. In the ox the 17-hydroxylating enzyme system appears to be in the zone lying under the glomerulosa only, whereas the 18-oxidase system necessary for aldosterone synthesis is confined to the glomerulosa zone.

A remarkable feature of the adrenal cortex is its ability to synthesize all known types of steroid hormones. R. V. Short discussed the biosynthesis and secretion of sex hormones by the adrenal gland. In his laboratory, methods have been developed for the separation and determination of the major and some of the minor steroid constituents of adrenal venous blood. These have been applied to the analyses of blood collected from human subjects by A. P. M. Forrest in Glasgow, and from adult, new-born and fœtal domestic animals by Dr. Short's collaborators in Cambridge. Progesterone has been found in adrenal blood from women, cows, sheep and pigs in concentrations higher than in the peripheral blood. 17α-Hydroxyprogesterone, a steroid which is sixty times as active as progesterone in some biological assays, has been detected in the adrenal venous blood of women and cows. The interesting observation has been made that young calves secrete 20α-hydroxypregn-4-en-3-one. This disappears from the secretion some time after birth and is replaced by the 20β-epimer in the adult animal. The significance of this is unknown. There is good indirect evidence for the secretion of œstrogens by the adrenal cortex, but they must be present in human adrenal venous blood in amounts too small for detection by present methods. Four androgens have been reported in adrenal-vein blood in man. Dehydro*epi*androsterone is probably exclusively of adrenal origin, but its precursors are still uncertain. Androstenedione is undoubtedly the most biologically active adrenal androgen and it may be present in adrenal venous blood in relatively high concentration. It is remarkable that androstenedione and dehydro*epi*androsterone cannot be detected in even large samples of adrenal venous blood in cattle. 11β-Hydroxyandrostenedione is probably present in the adrenal venous blood of the cow and sheep as well as in that of the rat and cat, but this compound, in common with the other known 11-oxy C_{19} steroids, seems to possess little biological activity. These observations may be of considerable importance in veterinary medicine and cast doubts on the reports of adrenal virilism in cattle.

The amount of corticosterone and hydrocortisone secreted by the adrenal cortex is controlled by corticotrophin from the anterior lobe of the pituitary. How the pituitary obtains the information necessary to enable it to adjust the activity of the adrenal cortex to the body's requirements is a fascinating question which has recently attracted much attention. Knowledge of this matter was reviewed by Marthe Vogt. Few histologists consider the nerve supply to the adenohypophysis adequate for the control of corticotrophin secretion, and this control is therefore assumed to be humoral. It has been shown that substances such as adrenaline, which may be carried by the systemic blood, can promote the release of corticotrophin by the pituitary. There is also much evidence in support of the view that a stressing stimulus results in nervous activity in the hypothalamus which elaborates a 'corticotrophin-releasing factor'. This is carried by a 'portal' circulation to the anterior lobe, where it stimulates corticotrophin secretion. The original suggestion that the corticotrophin-releasing factor is identical with vasopressin has been modified by the independent observations of Saffran and Guillemin, who now propose that it is a polypeptide similar to but different from vasopressin. The purified material is active *in vitro* in nanogram amounts, and microgram quantities produce a similar effect on the rat pituitary stores of corticotrophin or on blood corticosteroids as severe stress. The active material contains seven of the eight amino-acids of lysine-vasopressin and, in addition, serine and histidine. Dr. Vogt also discussed the nature of stimuli which activate or inhibit hypothalamic activity. The level of corticosteroids in blood is now regarded as a contributing, but not the sole, factor accounting for the control of corticotrophin secretion in stress. Recent work suggests that the suppressing effect of high doses of corticosteroids may be on the hypothalamus rather than on the pituitary. In addition to lack of corticosteroid in the blood, afferent nervous impulses, especially if they elicit pain or worry, stimulate the release of corticotrophin, but the nature of the stimulus or stimuli which act in other forms of stress is unknown. General depressants of the brain inhibit the release of corticotrophin.

Dr. Vogt also reviewed knowledge of the control of secretion of aldosterone. This secretion is less influenced by corticotrophin than that of the glucocorticoids. Farrell has, however, recently found that certain preparations of corticotrophin increased aldosterone secretion in the decerebrate, hypophysectomized dog, but satisfactory evidence for the existence of a specific pituitary hormone which influences aldosterone secretion is lacking. The role of such a hormone would be limited, since increased aldosterone secretion in the hypophysectomized dog has been obtained with a variety of stimuli. Experiments in Dr. Vogt's laboratory have demonstrated the rapid and reversible response of aldosterone secretion in the dog to expansion and contraction of the intravascular volume. Infusion of blood decreases, whereas hæmorrhage increases, the secretion of aldosterone. The former effect was less easily elicited than the latter.

In the final paper, N. Saba dealt with the mode of action of corticotrophin from the biochemical point of view. He referred to the observations of Hechter that corticotrophin acts on the conversion of cholesterol to pregnenolone and the later independent work of Heard and Grant on the stimulation of

11-hydroxylation by the trophic hormone. Saba's results obtained in collaboration with Hechter suggest that corticotrophin influences the spatial relationships of enzymes involved in the biosynthesis of adrenocortical steroids. More recent work by others has revealed an effect of corticotrophin on enzyme systems which effects the reduction of triphosphopyridine nucleotide. The requirement for reduced triphosphopyridine nucleotide for steroid hydroxylation has already been referred to. If this is an important effect of corticotrophin it is difficult to relate it to the specificity of action of this hormone.

J. K. Grant

EDUCATION IN THE UNITED STATES (1957–58)

Education in the United States of America is based on three fundamental concepts: that the primary responsibility for public education rests with the States; that every person has an equal right to educational opportunities; and that educated citizens are essential to freedom and human welfare. Working within these concepts during 1957–58 the United States made further progress towards its goal of improving education for all*.

Evidence of progress is found in the increasing educational attainment of the population. The number of school years completed by the average adult 25 years of age and over increased from 9·3 in 1950 to 10·6 years in 1957. The group 25–29 years had completed 12·3 years of schooling, while the group older than 65 had completed only 8·3 years.

Although education is a State responsibility, no State administers its schools directly. Laws have been enacted in each State dividing the territory of the State into local school administrative units commonly termed school districts. The powers of local district school boards to establish and maintain schools are prescribed by State law, but permit exercise of local initiative in exceeding minimum educational standards required by the State. Each State has its own department of education, which exercises controls and provides specialized services to assist local school districts in conducting the State programme of education.

At the beginning of the school year there were 1,152,500 instruction rooms in full-time public elementary and secondary schools; an additional 142,300 rooms were needed to relieve over-crowding and to replace unsatisfactory facilities. About 70,500 instruction rooms were scheduled to be built during the year. About 61,000 rooms will be needed to accommodate next year's enrolment increase and to replace rooms that will probably be abandoned.

Almost one-third of all pupils enrolled in the public elementary and secondary schools are transported to and from school at public expense. During 1955–56, more than 10 million pupils were transported. In most States pupils must live 1½ miles or more from the school to be eligible for transportation for which the State helps to pay the cost.

Institutions of higher education classified by type of support and control are of two general types—publicly controlled and privately controlled. One-third of the approximately 1,900 higher institutions are publicly controlled and supported by public or government agencies; two-thirds are privately controlled and supported by individuals or ecclesiastic, philanthropic and other groups. The State exercises little control over institutions of higher education, even those supported by public funds, and consequently both types of institution operate with a high degree of autonomy.

In 1957–58 expenditures for education in public elementary and secondary schools and in higher institutions totalled 20,000 million dollars, which was 5·5 per cent of the 1957 total national income of 358,000 million dollars. Funds to cover expenditure in public schools were provided by Federal, State and local governments.

For the fiscal year 1958 the Federal Government appropriated approximately 2,000 million dollars for educational purposes. The total included funds administered by the Office of Education and was distributed as follows: Office of Education, 7,000,000 dollars; vocational education, 40,888,412 dollars; higher education, 5,051,000 dollars; school construction and maintenance, 225,650,000 dollars; and library services, 5,000,000 dollars.

Since the States have primary responsibility for public education in the elementary and secondary schools they provide funds and authorize local school districts to provide local tax-funds for public schools. In the 1957–58 school year it is estimated that of the total revenue for public schools the Federal Government provided 4 per cent; the States, 41 per cent; and local districts, 55 per cent. In recent years the percentage from Federal and States funds has been increasing slightly.

As much as 93 per cent of local educational revenue is obtained from property taxes. Local communities use the property tax to secure funds for current operating expenses and for school construction. Some local districts also levy non-property taxes for schools, including local *per capita* taxes and taxes on wages, sales and amusements. Non-property taxes for schools produce 7 per cent of local revenue.

Total expenditure per pupil in 1957–58 averaged 431 dollars, an increase of about 7 per cent over the amount in 1955–56.

Tax revenues supply most of the funds for public institutions; private donations, student tuition and endowment supply most of the funds for private institutions. The 1957-budgets for both private and public institutions for educational and general expenditures, excluding auxiliary services, student aid and plant expansion, totalled 3,200 million dollars. Of this, students paid 950 million dollars as tuition; earnings on endowment provided 150 million dollars; private gifts, 250 million dollars.

The organization of public schools is determined by State and local authorities, but generally the basic 12-year programme is organized as an 8-year elementary and a 4-year secondary programme or a 6-year elementary and a 6-year secondary programme. Typically a 6-year secondary programme is divided into a 3-year junior and a 3-year senior high school. The most common type of school is one attended by almost all children of school age in the community, regardless of social or economic status, sex or vocational aim On all levels schools vary greatly in size, from one-room rural schools to large urban schools enrolling several thousand students Improvement of the school district organization in sparsely populated regions has resulted in a continued decrease in the number of small high-schools

---

* Progress of Public Education in the U.S.A., 1957–58. (Washington, D.C.: Gov. Printing Office; available also from H.M. Stationery Office, London.)

All States provide public schools and permit students between the ages of 6 and 20 years to attend Most States have enacted compulsory attendance laws for certain age-groups The compulsory attendance ages range from 6 to 18 years, but a majority of the States require attendance between the ages of 7 and 17 years Of the total population of persons between 6 and 17 years old in October 1957, 96 5 per cent were enrolled in school At that time 93 per cent of all school-age children, generally defined as those between 5 and 17 years old, inclusive, were enrolled In elementary and secondary schools the proportion of boys and girls was about the same but in higher-education institutions men made up about two-thirds of the student body and women one-third

School enrolments increased for the thirteenth consecutive year In 1957–58, 43,135,000 persons, or about one out of every four in the population, were attending public or private schools and colleges , an increase of more than 4 per cent over 1956–57

The latest available data indicate that about one-half of the high-school graduates now go to college, about 42 per cent full time and 8 per cent part time Attendance of students at institutions of higher education is altogether voluntary Assuming that they meet admission requirements, students are free to choose the type of institution they attend—public or private, liberal arts or technical, 2-year or 4-year, and to pursue any curriculum or prepare for any profession to the extent of their abilities A student in an institution may of his own volition drop out altogether or transfer to another institution In the autumn of 1957, colleges and universities enrolled more than 3 million students, an increase of 4 per cent over the autumn 1956 enrolment, and a 43 per cent increase over the 1952 autumn enrolment The number of freshmen entering college in the autumn of 1957 represented slightly more than 30 per cent of persons in the country who were 17 years of age in 1956 About 58 per cent of the students enrolled were in public institutions Enrolment in public institutions is increasing more rapidly than in private. About 800,000 of the students attending full time lived in dormitories provided by the institutions

The degree-granting colleges conferred a total of 411,000 degrees in 1957–58, 8 3 per cent more than in 1956–57 Of the total conferred, 82 8 per cent were bachelor's, 15 1 were master's and 2 1 were doctor's degrees The average cost of a year in college was between 1,500 and 2,000 dollars, and the median award in scholarship aid was less than 300 dollars

In 1957–58 between 30 and 35 million adults participated in adult education programmes sponsored by industry, labour unions, the Armed Services, farm organizations, and other groups In carrying out their programme, these groups had the co-operation of public libraries, public school systems, higher institutions, television systems and Government agencies

Extensive research is carried on by public and private agencies such as colleges and universities, State departments of education, and various philanthropic groups Their research is directed toward solving some of the problems facing education , for example, it includes further investigation of the learning process and the character and extent of individual differences State departments and local school systems direct their research primarily to solving local problems, and colleges and universities direct theirs to broader problems in education

THE PHYSICAL SOCIETY, 1958–59

THE annual general meeting of the Physical Society was held on May 21 at the Royal Institution, London, and immediately following the meeting Mr J A Ratcliffe delivered his presidential address entitled "Recent Trends in the Theory of the Ionosphere" The report of the council of the Society and the accounts and balance sheet for 1958 were adopted at the meeting and the composition of the new council to hold office for the session 1959–60 was announced

The income of the Society during 1958 exceeded expenditure by £4,581 and was mainly due to the increase in price of the Society's publications when sold to the general public which the council authorized in 1957 Notwithstanding the rise in price, sales have increased The membership rose from 2,069 to 2,136, but the increase was entirely in the student membership grade The forty-second annual exhibition of scientific instruments and apparatus was held during March 24–27 in the two halls of the Royal Horticultural Society The size of the exhibition and attendance were similar to those of the previous year The sales of the exhibition handbook and the receipts from exhibitors resulted in a satisfactory surplus of £5,905, of which £4,000 was transferred to the exhibition contingency fund and the remainder to the general income and expenditure account

The council's report refers briefly to the activities of the Society during the year and in particular to the conferences of two or three days duration which were held on various subjects in Cambridge, Durham, Malvern and Swansea The attendances were usually between 200 and 250, of which approximately half on the average were members of the Society A few research students and others were financially assisted to attend these conferences by means of a grant allotted to the Society by the Royal Society The decision to recombine the two sections of the Society's *Proceedings* was put into effect during 1958 and the volume of work published (208 original articles, 74 research notes and 21 letters to the editor) was substantially the same as in 1957 Vol 21 of the "Reports on Progress in Physics", which was published during the summer, contained nine articles, and these articles were also available for purchase separately

The informal discussions with the Institute of Physics which were begun in 1957 to consider the closer co-operation between the Institute and the Society were continued. A mutually agreed document entitled "Memorandum to Members—Proposal to Amalgamate the Institute of Physics and the Physical Society" was circulated, together with an explanatory letter from the president. A joint amalgamation committee has been set up and is now engaged in more detailed discussions.

At the annual meeting, the president, Mr. J. A. Ratcliffe, the honorary secretaries, Dr. C. G. Wynne, Dr. H. H. Hopkins and Mr. A. G. Peacock, the honorary foreign secretary, Prof. E. N. da C. Andrade, and honorary treasurer, Dr. D. A. Wright, were re-elected to serve for 1959–60. The newly elected vice-presidents were Prof. F. Llewellyn Jones and Dr. G. B. B. M. Sutherland, and the newly elected members of council Mr. D. W. Fry, Dr. V. E. Cosslett, Prof. F. C. Frank, Prof. W. E. Burcham, Dr. R. L. F. Boyd, Dr. R. A. Smith and Prof. D. H. Wilkinson.

S. WEINTROUB

SCHOOL MEALS IN ASIA AND THE FAR EAST

VARIOUS Food and Agriculture Organization conferences, as well as regional nutrition meetings convened periodically in co-operation with the World Health Organization, have emphasized the importance of supplementary feeding as a means of improving the nutrition of vulnerable groups. The First Regional Nutrition Committee in South and East Asia, which met in Baguio, the Philippines, in 1948, recommended a type of meal which could be supplied to school-children in the region. This meal pattern emphasized the use of cheap, locally available foods that would provide the children with all essential nutrients.

The Fourth Regional Nutrition Committee of the two Organizations, which met in Tokyo in 1956, considered a number of important factors relating to school feeding programmes; it recommended that the Food and Agriculture Organization should convene a school feeding seminar for countries in South and East Asia, at which the future development of school-feeding along sound lines could be discussed by appropriate country representatives.

Much of the Food and Agriculture Organization's practical work in school-feeding has been done in co-operation with the United Nations Children's Fund, the Organization providing the technical guidance in organizing and developing programmes based initially on dried skim milk and other supplies made available by the Fund. This Fund has become increasingly interested in the long-term development of measures to improve the nutrition of children and has recently been authorized to increase the scope of assistance which it can provide. It was agreed, therefore, that the Fund should join the Organization in convening the seminar. Because malnutrition is often a serious problem among children of pre-school age, it was also agreed that consideration would be given to this important group of the population.

The seminar was designed to bring together, from the countries concerned, workers associated with various aspects of child-feeding programmes, in particular school-feeding programmes, for consideration of the problems met in developing them and of measures needed to improve and expand them on a sound nutritional and financial basis. The Government of Japan extended an invitation for the seminar to be held in Japan, and it was held in International House, Tokyo, during November 10–19, 1958. The seminar was attended by delegates from twelve countries in the region, as well as by representatives from the World Health Organization, International Co-operation Administration, and Co-operative for American Remittances to Everywhere. A report on the seminar has now been issued (H.M.S.O., 2*s*. 6*d*.).

INDUSTRIAL HEALTH IN THE POTTERIES

DURING 1956–58, four members of the factory inspectorate carried out a survey of industrial health in the pottery industry in the Stoke-on-Trent area. The survey was undertaken with the advice of the Industrial Health Advisory Committee. This Committee was set up in 1955 by the Minister of Labour and National Service to advise him on measures to further the development of industrial health services in work-places covered by the Factories Acts.

On the advice of the Committee the Minister instituted two industrial health surveys, which were to be regarded as pilot surveys. The first was of all the factories in a particular area—the town of Halifax was chosen—and the report on that survey was published in 1958. The second was a survey of a specific industry—the pottery industry.

A number of considerations led to the choice of the pottery industry. Among them was the fact that it is geographically compact, and that, although over a number of years much has been done in the industry to eliminate or reduce the known health risk, it was considered that a survey of the pottery industry would have particular interest in giving an opportunity to assess both the success of the measures so far taken and the continuing needs.

Although a survey of this kind offers no basis for comparing conditions in the pottery industry with those of other industries, it is possible to draw some comparison between present conditions in the pottery industry and those of the past. General conditions in the industry to-day are markedly different from what they were. The industry has done a great deal, particularly in the years since the end of the Second World War, to improve working conditions and to reduce the health hazards connected with pottery manufacture.

The classic industrial disease of the pottery industry was lead poisoning, due in part to the lead glazes used. By the middle 1940's the use of low-solubility or leadless glazes had become so widespread that it was considered practicable to prohibit the use of any glaze that was not either leadless or of low solubility. This was not an easy requirement for all firms to comply with, and the glazed tile industry was faced with a particularly difficult problem. Intensive research enabled all firms to be in a position to comply with the requirement when it became law. The other source of lead poisoning was the colour used in decorating the ware. Higher standards of cleanliness and improved methods of dust control have, so far, dealt with this hazard, with the satisfactory result that in recent years lead poisoning has virtually been eliminated from the industry.

Another major achievement of the industry, this time in reducing the risk of pneumoconiosis, has been the substitution of alumina for powdered flint in the placing of china for the biscuit fire. When it became clear that alumina was a satisfactory alternative, the china industry, in spite of some technical problems involved, agreed that the flint should be replaced by alumina. By 1947, when this change was made compulsory, all firms in the industry had in fact changed over.

Work on the control of dust in the making processes, where there is a health hazard from pneumoconiosis, is continuing. For some years the British Ceramic Research Association has been working on the dust problems of the industry, and has done much valuable research work into the behaviour and control of dust given off in certain processes. The Research Association has already designed dust-control plant for the processes of towing and hollow-ware fettling which is proving most effective. Work is in progress on the control of dust in the dust tile-making processes, and to determine the most suitable material for workers' overalls where there is need to protect them against dust.

To provide a continuing forum for discussion of the health and safety problems of the industry, the Chief Inspector of Factories in 1956 appointed a Joint Standing Committee of the Pottery Industry. With the help of the British Ceramic Research Association, it has published an advisory booklet on dust-extraction in the pottery industry. It has also directed the attention of industry to the dangers inherent in the use of hydrofluoric acid in cleaning gold, encouraging the use of other methods which it has made known.

The aim of the survey was to present an objective picture of existing conditions in the industry and to indicate outstanding problems. The visits made by the inspectors have been followed up by action to secure improvements. The work that requires to be done in order to deal with outstanding problems is under examination by the Joint Standing Committee (H.M.S.O., 5*s*.).

DEVELOPMENTS IN TRAINING

A SERIES of five papers on training were given at the Polytechnic, Regent Street, to an audience of two hundred directors and industrial executives during January and February, 1957. They have now been reprinted and form a valuable addition to the scanty information available for those concerned with all aspects of training in industry*.

The first, by Prof. J. Z. Young, deals with the fundamental aspects of learning by drawing on biological studies of organisms at all levels of complexity. Developing the importance of perception in learning, W. D. Seymour, of the Department of Engineering Production in the University of Birmingham, produces evidence to show that carefully devised training procedures for manual skills which take account of recent findings will usually halve the normal learning period. In the third lecture, Mrs. W. Raphael, assistant director of the National Institute of Industrial Psychology, describes the in-plant training being carried out in seven European countries and shows that the training provided for operatives exists largely in name only. F. A. Heller, head of the Department of Management Studies at the Polytechnic, shows how the development of managerial skills can be approached from the same biological and analytical points of view as any other skill training. Like other lectures in the series, he pays special attention to the methods rather than to the content of training programmes. The fifth lecture was given by S. D. M. King, director of Organization and Training, Ltd., who used case-studies to illustrate the importance of relating training to a carefully devised policy at all levels of an organization.

ERGONOMICS

THE development of modern industry with the substitution of mechanization for craftsmanship has brought new problems; the machine has reached the point where it is no longer the limiting factor in production and this in turn is imposing new stresses and strains on the operator, who can no longer be left to get along as best he can. That this was beginning to happen began to be realized about fifty years ago, and early developments in fitting the job to the man, like the motion study of Gilbreth, were part of scientific management for increasing production through reduction of fatigue. Men of the biological sciences began to become aware that people at work were worthy of study and that remarkably little was known about their capabilities and aspirations.

It took the added stress of two world wars to stimulate any real interest. A start was made in the First World War when groups of physiologists and psychologists such as the Industrial Fatigue Research Board in the United Kingdom started work. Between the wars progress was slow, perhaps because a general labour surplus removed a demand for maximum economy in use of labour; but during and since the Second World War the research effort has been vastly intensified. Much of it gained its initial impetus from the armed forces and has, particularly in the United States, continued to be supported by them. In other countries research has been much more directed towards solving industrial problems, as typified by that done by work physiologists in Sweden and Germany.

The fragmentation of the subject into a number of disciplines independently studying human work could not continue indefinitely, and the first fusion occurred in the United Kingdom in 1949 with the formation of an interdisciplinary society and the coining of the term 'ergonomics' to cover the study of human work. Although the British society attracted adherents from all over the world it soon became clear that a truly international meeting was needed. The initiative was taken by the European Productivity Agency in the form of Project 335, the final aim of which is a tripartite international conference of scientists, employers and employees. As a preparation for this, two preliminary steps were taken. The first was to send a mission to the United States to report on the situation there, and the second was to hold a technical seminar to assemble information on progress in Europe. A report has now been issued, part one of which contains the report of the mission and part two a report on the seminar*. The tripartite conference has still to take place.

AN OCEANOGRAPHIC SURVEY OF THE ROSS SEA

By J. S. BULLIVANT

New Zealand Oceanographic Institute, Department of Scientific and Industrial Research, Wellington, New Zealand

IN January 1959 an oceanographic survey of the Ross Sea was carried out by members of the New Zealand Oceanographic Institute, from the New Zealand Antarctic Supply Ship H.M.N.Z.S. *Endeavour*.

The route taken by the *Endeavour* and the distribution of the twenty-four stations occupied are shown in Fig. 1. A brief station list is also included, particularly for the information of workers planning investigations in the area in the near future.

The aim of the survey was to investigate the hydrology, the benthic fauna and the marine sediments in the area.

The routine procedure at each station was to lower a bathythermograph (275 m.) and a cast of reversing bottles, make a vertical plankton haul from near the bottom to the top, collect phytoplankton, make three lowerings with a twin orange-peel grab sampler and collect epifauna from the bottom with a trawl. The grab sampler consisted of two modified four-blade orange-peel grabs, each having a bucket capacity of 24·5 litres, suspended one at each end of a 4-ft. bar.

In addition to these routine observations, surface water samples from stations *A*466 and *A*470 and a bottom water sample from *A*470 were obtained for determination of carbon-14 activity in order to study water movements in the Ross Sea and under the Ross Ice Shelf.

An underwater-camera and a bottom trawl were used at three stations (*A*468, *A*469 and *A*471) near Ross Island, to sample three different types of bottom community. Some of the photographs

*A*463	72° 20′ S , 174° 50′ E	21 1 59	468–465	barnacle plates	435	×	×	×	×	
*A*464	73° 20′ S , 174° 00′ E	22 1 59	369–384	sand pebbles	345	×	×	×	—	
*A*465	72° 55′ S , 175° 30′ E	22 1 59	399	barnacle plates	375	×	×	×	—	
*A*466	78° 26′ S , 174° 50′ W	24 1 59	569	mud	570	×	×	×	×	corer ^{14}C sample
*A*467	77° 25′ S , 169° 28′ E	26 1 59	88–183	rocks	—	×	—	—	×	
*A*468	76° 59′ S , 167° 36′ E	26 1 59	110	—	—	×	—	—	—	camera
*A*469	77° 50′ S , 166° 33′ E	29 1 59	64	gritty mud, spicules	—	—	×	×	×	camera
*A*470	77° 50′ S , 166° 30′ E	4 2 59	377	muddy sand	365	—	×	—	×	^{14}C samples
*A*471	77° 37′ S , 166° 20′ E	6 2 59	165–69	—	—	×	—	—	—	camera

revealed a surprisingly dense epifauna, dominated by sponges and Bryozoa (Fig 2)

A gravity corer was used at stations *A*458, *A*459, *A*460, *A*461 and *A*466, short cores were secured

Hourly surface water samples were taken on passage out of McMurdo Sound, and continuous surface temperatures were recorded during the greater part of the cruise

Of particular interest was the discovery of large deposits of calcareous barnacle plates The plates were found sparsely distributed over the whole of the Ross Sea, but at stations *A*463 and *A*465 in approximately 460 m and 400 m, respectively, these plates, together with scattered rocks on which a live barnacle was growing, formed the bulk of the bottom deposit The deposit also contained a small percentage of the calcareous remains of molluscs, bryozoans and corals, but as far as penetrated by the grabs and trawl was entirely free of mud or sand The living and dead barnacles belong to the genus *Hexelasma* Estimates of the age of the barnacle plates are to be made from determinations of their carbon-14 activity

The biological material collected is a substantial addition to that already available from Antarctic waters

Results of the survey will be published by the New Zealand Department of Scientific and Industrial Research

The wholehearted support the expedition received from the commanding officer and ship's company of H M N Z S *Endeavour* is gratefully acknowledged

CHANGE OF COSMIC RAYS IN SPACE

By PROF H V NEHER

Norman Bridge Laboratory of Physics, California Institute of Technology, Pasadena

THE advent of space rockets now makes possible direct measurements on quantities that have heretofore suffered from the interference of the Earth, its atmosphere or its magnetic field Among these are measurements on cosmic rays The absorption of the radiation in the Earth's atmosphere and the analysing effect of its magnetic field have, however, yielded valuable information on the total energy content and the individual particle energy From such measurements, together with a knowledge of their chemical composition, one can deduce the intensity or number of primaries in space When this is done, using results collected over a period of years obtained with balloons at various latitudes, one finds surprisingly large time variations in the numbers of primary particles In what follows we discuss what such measurements have so far disclosed about the absolute intensity and how it varies with time Some preliminary measurements have already been made in rockets, and further measurements, giving more complete checks on these calculations, will undoubtedly come in the future

A brief note concerning these large changes, based on data taken in 1954 and 1957, has already been published[1] We wish here to present two additional methods of arriving at the numbers of primary particles in 1954 together with new results taken near the north geomagnetic pole in the summer of 1958 when the intensity there was even lower than in 1957

The period 1954–58, when solar activity went from a minimum to a maximum of activity, provided

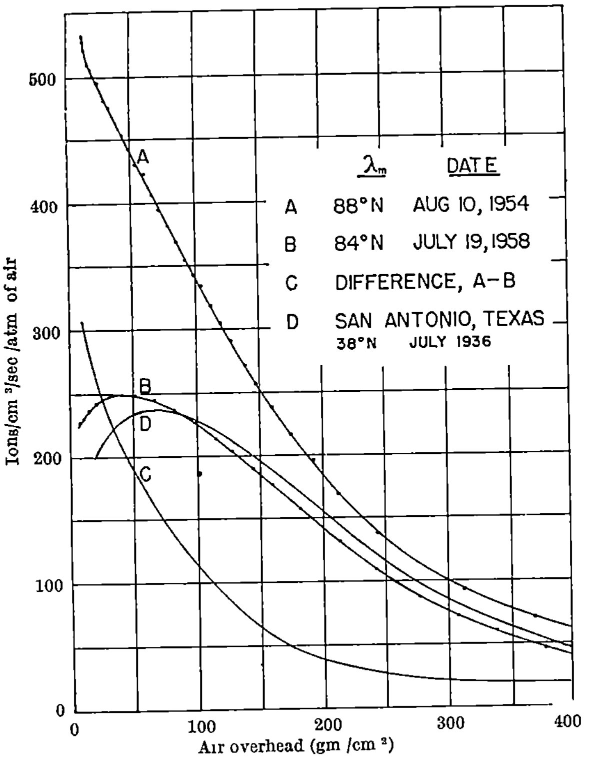

Fig 1 Curves A and B show the extremes of the ionization so far measured with balloons near the north geomagnetic pole Curve A represents data taken at the solar minimum of 1954, while curve B represents the situation near the solar maximum of 1958 The absorption in the atmosphere of the particles present in 1954 but which were absent in 1958 is given by curve C

an excellent opportunity to study the changes produced in cosmic rays Fig 1 shows how large these changes have been near the north geomagnetic pole The behaviour of curve A was typical of the curves from five similar balloon flights[2] made with ionization chambers in July and August 1954 All five records showed the same turn-up of the ionization curve at about 15 gm cm $^{-2}$ It was shown in ref 2 that the behaviour of curve A at low pressures was consistent with the absorption of low-energy particles and that the turn-up was probably due to the absorption of protons with energies down to at least 150 MeV

By 1958, the character of the radiation at the pole was radically different The largest decrease occurred in the year 1956-57[1] As shown by curve B, the ionization at high altitudes was less than half its value in 1954 In fact, the area under curve B is about 3 per cent less than the area under the curves taken in 1936 at San Antonio, Texas[3] (geomag lat 38° N) It should be remarked that we feel confident that a direct comparison can be made between these years, for we not only have instruments which we have compared through the years but we have also checked their absolute calibration by using standard capacitors

Our first method of estimating the number of primaries in 1954 is to calculate the number causing the difference between 1954 and 1958 and then adding to this the number present in 1958 To arrive at this latter figure we note that due to the nearly equal areas under curves B and D of Fig 1 and to the similarity of shape, the number of primaries must be about the same Taking the difference in area at the lower pressures and assuming a mean energy of 3 BeV per particle causing this difference, we find that the number of primaries involved is approximately 0 007 cm $^{-2}$ sec $^{-1}$ sterad $^{-1}$ Previous calculations[4] have shown that the number of primaries present at San Antonio in 1936 was 0 040 cm $^{-2}$ sec $^{-1}$ sterad $^{-1}$ This number is consistent with the measurements of MacDonald[5] at the equator, together with the increase in energy brought in by the primaries as one goes from the equator to 38° N We thus find that the number of primaries present in 1958 near the pole was 0 047 cm $^{-2}$ sec $^{-1}$ sterad $^{-1}$

Referring now to Fig 1, curve C shows the difference between A and B and represents the absorption in the atmosphere of those particles that were present in 1954 but were absent in 1958 A Gross transformation of this difference curve shows that the major part of the area under the curve is due to particles the effect of which varies nearly linearly with thickness of atmosphere The fact that curve C has a tail that extends even to sea-level is undoubtedly due to mesons formed in the upper part of the atmosphere and especially by the higher-energy primaries that also change during a solar cycle

Ignoring the high- and low-pressure ends, the bulk of the area may be accounted for by particles with a maximum range of about 300 gm cm $^{-2}$ in air Assuming a range proportional to the energy, we may say with sufficient accuracy that the Gross transformed curve corresponds to a differential number distribution that is independent of energy

We shall here assume that 15 per cent of the primaries responsible for curve C are α-particles, 2 per cent of average $Z = 8$ and the remainder protons We find that we need protons of mean energy 0 55 BeV , α-particles of mean energy 2 2 BeV and for $Z = 8$, a mean energy of 1 2 BeV per nucleon, for each to have a mean range of 150 gm cm $^{-2}$ We then arrive at a weighted mean energy of 1 5 BeV per particle The area under curve C is 1 00 × 10^9 eV cm $^{-2}$ sec $^{-1}$ Hence the number of particles per unit of horizontal area is 0 67 cm $^{-2}$ sec $^{-1}$ Thus per unit of solid angle we have, 0 21 cm $^{-2}$ sec $^{-1}$ sterad $^{-1}$

To arrive at the total number of primaries at the pole in 1954 we add to the above the number present in 1958 We have already found this to be 0 047 cm $^{-2}$ sec $^{-1}$ sterad $^{-1}$ In this manner we find the total at the top of the atmosphere near the pole in 1954 to be 0 26 par sec $^{-2}$ sec $^{-1}$ sterad $^{-1}$

Another method of arriving at the number of particles responsible for the difference between 1954 and 1958 is to estimate the mean specific ionization per particle at the top of the atmosphere and, knowing the ionization, the number of particles immediately follows

Taking the mean energies of the protons, α-particles and average $Z = 8$ for the heavy primaries, as given above, we find that the specific ionization relative to that for a minimum ionizing particle of unit charge has the values 1 3, 5 2 and 64 respectively Using the relative abundances cited before and published curves on energy loss, we find the average specific ionization for these time-varying particles at the top of the atmosphere at the pole to be 210 ion pairs cm $^{-1}$ in air at 1 atm If $\bar{\sigma}$ is this mean specific ionization and there are J particles cm $^{-2}$ sec $^{-1}$, then the ionization, $I = \bar{\sigma}J$ Since $I = 350$ ions cm $^{-2}$ sec $^{-1}$ atm $^{-1}$ of air from Fig 1, then $J = 1$ 67 The instrument is receiving particles from a solid angle of 2π Hence the uni-directional intensity is 0 26 par cm $^{-2}$ sec $^{-1}$ sterad $^{-1}$ This method then gives a total of 0·31 par cm $^{-2}$ sec $^{-1}$ sterad $^{-1}$ at the pole in 1954.

A third method of arriving at the numbers of particles is to take the increments in the area under the ionization-depth curves for changes of latitude. This was done in 1954 from Boston to Thule, Greenland, using Bismarck as a base station to take account of temporal changes. The results of this analysis have been published[2]. These calculations gave a total of 0·24 par. cm $^{-2}$ sec $^{-1}$ sterad $^{-1}$ at the pole.

These three values, 0·26, 0·24 and 0·31, then give an average of 0·27 par. cm $^{-2}$ sec $^{-1}$ sterad $^{-1}$ at or near the north geomagnetic pole in the summer of 1954. An application of Liouville's theorem tells us that with an isotropic distribution at infinity, this was also the intensity in space at that time. The corresponding total intensity in space was then 3·1 cm $^{-2}$ sec $^{-1}$ through a sphere of unit area.

In 1958, the intensity at or near the pole was 0·047 cm $^{-2}$ sec $^{-1}$ sterad $^{-1}$ or 0·59 cm $^{-2}$ sec $^{-1}$, as discussed above. We thus arrive at the conclusion that the numbers of particles in space near the Earth, but sufficiently far removed to be free from any of its effects, changed by a factor of 5 during this period of four years. This is probably a lower limit, for we do not know how high the ionization would have gone in 1954 had our balloons gone higher.

So far, data on the number of cosmic-ray particles in space have been obtained by both the United States and the U.S.S.R. On the journey of *Pioneer IV* which went near the Moon and is presumably now in orbit around the Sun, the data at large distances gave 1·8 ± 0·3 particles cm $^{-2}$ sec $^{-1}$. (I am grateful to Prof. J. A. Van Allen for giving me this figure.) This rocket was launched on March 3, 1959. For the Russian cosmic rocket, launched on January 2, 1959, the value measured[6] was 2·3 cm $^{-2}$ sec $^{-1}$. These values are to be compared with the above calculated values using ionization chambers of 0·59 cm $^{-2}$ sec $^{-1}$ in 1958 and 3·1 cm $^{-2}$ sec $^{-1}$ in 1954.

There are at least two reasons why the values measured in these rockets at the beginning of 1959 are higher than those calculated from terrestrial measurements in the summer of 1958. (1) Cosmic-ray intensity near the orbit of the Earth appears to have reached a minimum near the summer of 1958 and had definitely started to climb[7] by January of 1959. (2) The instruments in each of the rockets were surrounded by the material of the vehicle. One would therefore expect the number of secondary particles to be an important factor. This would be especially true for the Soviet rocket, which was quite massive. To avoid the uncertainty of the contribution of surrounding matter, the detecting instrument would need to be ejected from the vehicle and remain at some distance away.

For those interested in space travel, an estimate may be made of the radiological intensity of cosmic rays in space. From Fig. 1 we see that the ionization at the pole was at least 530 ions cm $^{-3}$ sec $^{-1}$ atm $^{-1}$ of air at the highest altitude reached. In space, where the shielding effect of the Earth is missing, this number would be just doubled. In terms of radiological units we would then expect at a solar minimum to have at least 1,060 ions cm $^{-3}$ sec $^{-1}$ atm $^{-1}$ of air = 1·8 mr (milliroentgens) per hr. At the solar maximum of 1958, we found the total intensity in space across unit sphere to be 0·59 par. cm $^{-2}$ sec $^{-1}$. Assuming an average specific ionization of 200 ions cm $^{-1}$ of path in air at 1 atm., we find an ionization of 120 ions cm $^{-3}$ sec $^{-1}$ atm $^{-1}$ of air or 0·21 mr per hr.

It is to be hoped that as time progresses data from instruments in rockets will give us more definite information as to the mechanism that causes these large changes in the primary cosmic radiation.

The assistance of the Office of Naval Research in making the necessary arrangements to carry out this programme is greatly appreciated. I would also like to thank the Office of Naval Research, the Atomic Energy Commission and the National Academy of Sciences through the International Geophysical Year for financial support.

STUDIES OF COAL

By STAFF OF THE BRITISH COAL UTILISATION RESEARCH ASSOCIATION

Carbonization of Coals in the Presence of Activated Charcoal

It has been reported recently by Adams *et al.*[1] that the pyrolysis products of coal, if left in contact with a hot carbonaceous surface, undergo further reactions. Experiments in our laboratories[2] have yielded further results of a similar kind with respect to the behaviour on heating of coal mixed with, or overlaid by, charcoal.

Measurements of the amount of tar-like pyrolysis products emitted on burning briquettes made from mixtures of a low-rank coal and an activated charcoal (prepared from a coal char) showed a decrease as the proportion of coal in the mixture decreased, but more markedly than was to be expected from a dilution effect. On the other hand, briquettes made from the same coal mixed with an unactivated char-coal did not show a disproportionate reduction. It thus appears that the tar-like pyrolysis products evolved during heating were cracked on the extensive surface of the activated charcoal. The surface area that would be accessible to the large molecules likely to be present in these volatile vapours would be about 200 m ^{2}/gm., whereas the accessible surface area of the unactivated char would be less than 5 m ^{2}/gm.

When mixtures of coal and activated charcoal, or beds of coal overlaid with activated charcoal, were heated in a slow stream of nitrogen, or at a reduced pressure, to about 600° C., no tarry material was formed; instead, it was possible to collect in cooled traps an almost colourless liquid. This liquid was found, by infra-red analysis, to be composed of simple organic molecules (the benzene and toluene yield was in the range 0·3–0·7 per cent of the dry coal weight, compared with 0·1 per cent from the coal alone).

Table 1 Yields of Products from the Carbonization to 600° C of a Low-rank Coal (N C B Type 902) overlaid with Activated Charcoal
(Percentages of dry coal weight)

Ratio of charcoal to coal	Acidic aqueous liquor	Tar oil		Combustible gas		Carbon dioxide	Carbon deposited in the charcoal	Total
		Total	Benzene + toluene	Total	Paraffin to hydrogen ratio			
0	9 7	10 0	0 11	7 2	1 5	3 0	0	29 9
¼	9 7	2 7	0 36	8 8	1 5	3 7	5 3	30 2
½	9 7	1 4	0 46	8 5	1 4	4 7	5 5	29 7
1	9 7	1 2	0 72	8 5	1 3	6 8	6 0	31 2

The gaseous material evolved from the bed was found to be different from that obtained from the carbonization of the coal alone and, further, it was deduced from weight balances for the system and from analysis of the charcoal after use that carbon had been deposited in the charcoal

In Table 1 are compared the results obtained from the carbonization to 600° C of a low-rank coal (N C B type 902) with those from the same coal overlaid with an activated charcoal

When smaller proportions of charcoal were used in the carbonization experiments it was found that the condensates became slightly coloured and their complexity was increased The charcoal could be used again, provided the deposited carbon from the cracking process, which reduced the effectiveness of the charcoal, was removed by oxidation, for example, with steam at about 900° C There seemed to be little doubt that to achieve the complete elimination of dark tarry material from the condensates it was necessary for the vapours of the pyrolysis products of the coal to encounter a substantial amount of carbon surface The effect reported by Adams *et al* is not as great as that which we have observed , the reduction by only 1 per cent of the amount of tarry matter formed, and the slight increase in the amount of liquor, suggest that but little carbonaceous surface was available for cracking the coal 'volatiles'

It could be concluded that if a large amount of a pre-carbonized char, sufficient to have the necessary available surface area, was overlaid upon a 'green' coal and the whole was heated, very little tar would be formed, although some benzole would be obtained together with a gas of useful calorific value

Smoke Emission from Coal and Low-Temperature Chars

Work by this Association in a laboratory apparatus[1-3] has confirmed the observations of Piersol[4], afterwards verified by Adams, Games, Gregory and Pitt[5], that volatile matter is not an adequate guide for the amount of smoke produced from chars In Fig 1 it will be seen in all cases that chars prepared from a low-rank coal produce less smoke than coals with equivalent volatile matter Although Piersol[4] claimed a straight-line relation between the amount of smoke liberated under standard conditions of testing and the percentage of volatile matter in a range of coals, we did not find a direct proportionality (Fig 1) There is a general tendency for smoke emission to decrease with decreasing volatile matter, but highly caking and swelling coals tend to mask this trend McHugo, Shaw and Whittaker[6], who burnt a range of coals in a domestic appliance, observed a similar effect

We found a relation between tar-yields (Gray King assay at 600° C) and smoke emission for a number of samples, similar to that found by the Coal Research Establishment workers[5] We decided to extend the investigation into the relation between the hydrogen content of coals and their smoke emission for the following reasons

(1) Spooner[7] maintained that the tar yield of bright coals was related to their hydrogen contents Bradbury and Mott[8] therefore stated that, since tar yield and smoke emission are related, either the hydrogen content or the tar yield should serve as a guide to the amount of smoke produced We have also established a definite correlation between the tar yields (not given in this communication), and the hydrogen contents for the fuels which we examined (eighteen), the correlation coefficient being calculated as 0 93, which is found to be significant at the 0 001 level of probability

(2) Smoke is probably related in some manner to the chemical constitution of the fuel, particularly to the size and stability of the condensed aromatic ring clusters and the number of edge groups, which in turn are related to hydrogen content

(3) We have shown by statistical examination that when weight of smoke is plotted against volatile matter (Fig 1) the high-swelling coals follow a different relation from that for the low-swelling coals, the high-swelling coals producing more smoke than low-swelling coals with equivalent volatile matter

Fig 2 shows the general relation between the weights of smoke and the hydrogen contents of the coals and chars tested Both high- and low-swelling coals appear to follow the same relation

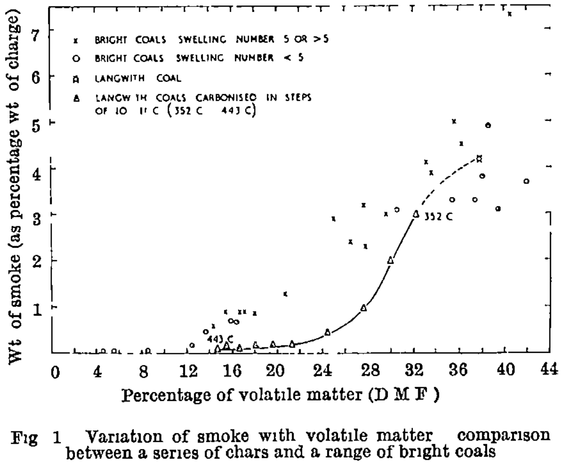

Fig 1 Variation of smoke with volatile matter comparison between a series of chars and a range of bright coals

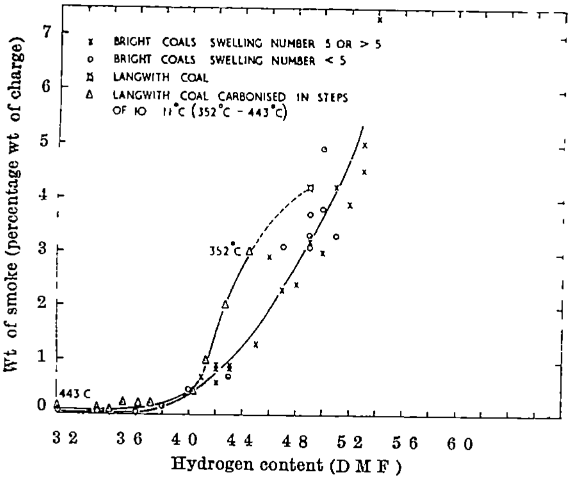

Fig 2 Variation of smoke with hydrogen content comparison between a series of chars and a range of bright coals

In Fig 2 the smoke emission from chars prepared from a low-rank coal is also plotted against their hydrogen contents and the curve obtained may be compared with that from the range of coals discussed above At the lowest carbonizing temperatures (352–382° C) there is a rapid rate of decrease in smoke emission As the carbonizing temperatures increase the rate of decrease decelerates At about 382° C (4 2 per cent hydrogen content D M F) the two curves meet Below this point the differences between the weights of smoke emitted for corresponding hydrogen values are so small they may be ignored, and for the purpose of the subsequent discussion the lower parts of the two curves may be regarded as coincident

From differential weight losses on Langwith coal[9] it is known that its pyrolysis begins about 335° C and the decomposition reaches a maximum rate at about 410° C Consequently, since chars produced at 400° C emit inappreciable amounts of smoke (Fig 2), it would seem that the low-boiling (low molecular weight) constituents which are first evolved are the main compounds responsible for smoke formation

Using infra-red techniques, Brown[10] examined a weakly caking and a strongly coking coal Between 440° and 550° C he found that hydrogen is lost by the removal of edge groups and the evaporation of small molecules followed by the loss of aromatic hydrogen and some graphitization at higher temperatures

The rank of coal[11] as well as the temperature of carbonization will affect the rate and type of decomposition and the structure of the residue These factors will obviously influence the constitution of the residue and the composition and amount of smoke evolved from a particular char during combustion The results with chars from Langwith coal may therefore be used only cautiously when coals of other rank are considered

When volatile matter is the abscissa and smoke the ordinate (Fig 1) then the curve for chars lies below that for coals, but when hydrogen content is the abscissa (Fig 2) the positions of the two curves are reversed

The explanation proposed is that although a char and a coal may yield the same volatile matter in the B S test, the constituents evolved may be quite different The coals will evolve moisture and low-molecular weight hydrocarbons which react and polymerize to form "tarry bodies"[12], whereas the chars will evolve hydrogen and other gases which ignite more easily or react together and condense less readily than those from coals Consequently, a coal with the same volatile matter as a char will produce more smoke It is not clear why a char with a hydrogen content equivalent to that of a coal yields more smoke

The laboratory work has suggested that either the tar yield or the hydrogen content provides a better indication of the amount of smoke emitted from coals than does the volatile matter Other work now in progress in these laboratories should indicate how far such relations hold for domestic open fires during ignition and steady-state combustion conditions

TWO ENZYMIC MECHANISMS FOR HYDROGEN TRANSPORT BY PHENOLIC ŒSTROGENS

By DR H G. WILLIAMS-ASHMAN, M. CASSMAN and MARGARET KLAVINS
Ben May Laboratory for Cancer Research and Department of Biochemistry, University of Chicago

ŒSTROGENIC steroids such as œstradiol-17β can mediate the enzymic transfer of hydrogen between triphosphopyridine nucleotide and diphosphopyridine nucleotide[1–3] The same enzyme concerned with this œstrogen-dependent transhydrogenation also catalyses both the reduction of these two nucleotides by œstradiol-17β, and the oxidation of their reduced forms by œstrone There is strong evidence[1,2] that, in the transhydrogenase reaction, the steroid transports hydrogen by the change steroid alcohol $\rightleftarrows$ steroid ketone

It has been suggested that this coenzymatic function of ovarian œstrogens is related to their mode of physiological action[1,2] However, powerful œstrogenic activity is exhibited by many phenolic compounds devoid of secondary alcoholic groups capable of reversible oxidation to ketone functions, and which fail (*a*) to act as coenzymes for hydrogen transfer in such systems^{1,3,4} and (*b*) to reduce pyridine nucleotides in the presence of the enzyme which catalyses the transhydrogenation Examples of such substances are 17-deoxyœstradiol^{5}, diethylstilbœstrol and hexœstrol^{6}, doisynolic and allenolic acids^{7}, and *iso*flavones such as genistein^{8} Accordingly, it became of interest to examine model enzymic systems for the transport of hydrogen by phenolic œstrogens of this nature Hochster and Quastel^{9} observed that, in the presence of manganese dioxide as a terminal hydrogen acceptor, diethylstilbœstrol acts as a hydrogen carrier in a number of dehydrogenase systems The quinone form of the œstrogen could be detected in the reaction mixture, and it was postulated to carry hydrogen in virtue of the reaction quinol $\rightleftarrows$ quinone The present experiments show that both natural and synthetic phenolic œstrogens function as hydrogen carriers in two other types of enzymic reaction The first of these is catalysed by certain phenolases and appears to involve an initial hydroxylation of the œstrogens to a corresponding *o*-diphenol, hydrogen is then transported by the change diphenol $\rightleftarrows$ quinone The second type of reaction is catalysed by some peroxidases, accelerated by traces of manganous ions, and implicates a free-radical form of the œstrogen as a hydrogen carrier It is well known that many simple, non-œstrogenic phenols can carry hydrogen in both enzyme systems However, the remarkable reactivity of many phenolic œstrogens in either type of reaction emphasizes that these substances can participate directly in hydrogen transport

Warburg^{10} demonstrated that phenolases (polyphenol oxidases) are copper proteins, and that small amounts of *o*-diphenols which are oxidized by such enzymes mediate the oxidation of reduced pyridine nucleotides^{10,11} We have found that phenolases purified from white potatoes and edible mushrooms oxidize reduced di- or tri-phosphopyridine nucleotides on the addition of trace amounts of many phenolic œstrogens The oxidations proceed to completion with the consumption of one atom of oxygen per mole of reduced pyridine nucleotide oxidized Fig 1 shows that with œstradiol-17β as carrier, a definite induction period occurs before the rate of oxidation of reduced diphosphopyridine nucleotide reaches a maximal value, whereas with the corresponding *o*-diphenol 1,3,5-œstratriene-3,4, 17β-triol^{12}, no such lag is observed Hexœstrol and 3-hydroxyhexœstrol behave in an analogous manner The activity of the mushroom and potato enzymes in these reactions parallels their phenolase activity (measured by the oxidation of tyrosine plus 3,4-dihydroxyphenylalanine) during fractionation procedures which result in purifications of more than fifty-fold The œstrogen-stimulated oxidation of reduced pyridine nucleotide is unaffected by catalase, but is abolished by heating the enzymes to 70° for 10 minutes, and by the addition of 0 001 *M* sodium cyanide The cyanide-inhibited enzyme can be reactivated by cupric ions Œstradiol-17β did not mediate the oxidation of reduced diphosphopyridine nucleotide in the presence of hæmocyanin, of copper sulphate (0 0001 *M*) or of the soluble phenolase of spinach leaves

A free phenolic hydroxyl group is essential for both natural and synthetic œstrogens to transport hydrogen by these phenolase-catalysed reactions Thus, nearly equivalent carrier activity is found with œstradiol-17α or -17β, 17-deoxyœstradiol, œstrone and œstriol, while 3-deoxyœstradiol-17α or -173 are completely inert *bis*-Dehydrodoisynolic acid is a good hydrogen carrier, whereas the corresponding O-methyl ether is inactive At least one phenolic hydroxyl group must be present in analogues of diethylstilbœstrol and hexœstrol^{13} to exert this carrier function The activity of natural and synthetic œstrogens is affected markedly by minor structural changes in the molecule Thus, 1-methyl-œstradiol-17β, 2-nitro-œstrone and 4-nitro-œstrone will not act as hydrogen carriers, and are without influence upon the action of œstradiol-17β 6β-Hydroxyœstradiol-17β (which does not mediate the oxidation of reduced diphosphopyridine nucleotide) and 7-keto-œstrone (which has approximately 10 per cent of the activity of œstradiol-17β), both at equimolar concentrations, depress the hydrogen-transporting activity of œstradiol-17β The concentrations of œstrogens permitting 50 per cent of the maximal rate of oxidation of reduced diphosphopyridine nucleotide by potato phenolase were found to be 1×10^{-6} *M* for 1,3,5-œstratriene-3,4, 17β-triol, 3×10^{-6} *M* for œstradiol-17β, œstrone, 17-deoxyœstradiol and hexœstrol, and 1×10^{-5} *M* for genistein

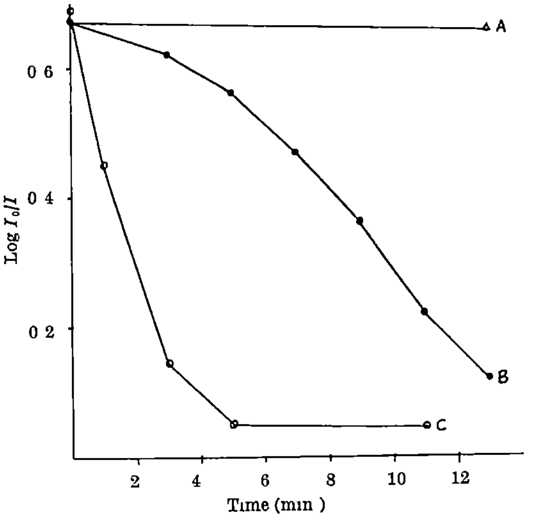

Fig 1 Oxidation of reduced diphosphopyridine nucleotide by phenolase in the presence of potato phenolase Sodium phosphate buffer *p*H 7 4 (0 05 *M*), 15 μgm œstrogenic phenol in 0 01 ml dioxane, 200 μgm potato phenolase, 0 3 μmoles DPNH Total vol 3 c c Light path 1 cm Wave-length 340 mμ 25° C in air *A*, no œstrogen, *B*, œstradiol 17β, *C*, 1, 3, 5, œstratriene- 3, 4, 17β triol

Hydrogen transport by phenolic œstrogens under these conditions can be described as follows The induction period with monophenolic œstrogens probably reflects the time required for the phenolase to catalyse hydroxylation to *o*-diphenol derivatives The diphenol is oxidized by the phenolase to the corresponding quinone, and the quinone is then reduced by the reduced pyridine nucleotide Although it is not known whether the latter reaction is enzymically catalysed or not, it may be mentioned that pyridine nucleotide-menadione^{14} and -quinone^{15} reductase activity is readily separable from the œstrogen-mediated reactions during purification of the phenolases In accordance with this formulation it was found that, after aerobic incubation with potato phenolase, diphosphopyridine nucleotide, ethanol and crystalline yeast alcohol dehydrogenase,

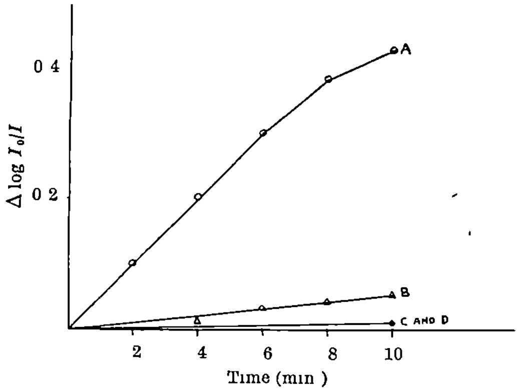

Fig 2 Oxidation of reduced diphosphopyridine nucleotide by peroxidase in the presence of œstrogenic phenols *Tris* (hydroxymethyl) amino methane buffer (0 03 *M*) *p*H 7 4, 0 3 μmole DPNH, 20 μgm œstradiol-17β in 0 02 ml ethanol, 0 03 μmole $MnCl_2$, 5 μgm horseradish peroxidase Total vol 3 c c Light path 1 cm 25° C in air Wave-length 340 mμ *A*, complete system, *B*, omit œstradiol-17β, *C* and *D*, omit $MnCl_2$ or œstradiol-17β and $MnCl_2$

œstradiol-17β is converted to at least two other substances which migrate much more slowly than œstradiol-17β when chromatographed on paper with a heptane–methanol solvent[16]

These findings are undoubtedly related to the reported inactivation of œstrogens by plant phenolases[17] It is possible that they have some bearing on the formation of hydroxylated derivatives of œstradiol-17β catalysed by liver microsomes in the presence of reduced triphosphopyridine nucleotide and oxygen[18], the stimulation of formate incorporation into isolated uterus by the addition of *o*-hydroxylated derivatives of œstradiol-17β *in vitro*[12], and the urinary excretion of 2-methoxy forms of œstrone[19] and œstriol[20]

An entirely different type of hydrogen transport mediated by phenolic œstrogens is catalysed by peroxidases purified from either horse radish or cow's milk Fig 2 shows that reduced diphosphopyridine nucleotide is oxidized upon the addition of peroxidase and low concentrations of œstradiol-17β, and that the reaction is stimulated by 10^{-5} *M* manganous chloride Manometric experiments revealed that the oxidation of reduced diphosphopyridine nucleotide proceeds to completion with the consumption of one atom of oxygen per mole of reduced diphosphopyridine nucleotide oxidized Reduced triphosphopyridine nucleotide and reduced nicotinamide mononucleotide are oxidized at the same rate as reduced diphosphopyridine nucleotide This phenol-dependent oxidation of reduced pyridine nucleotide does not require the addition of hydrogen peroxide Under these experimental conditions, hydrogen peroxide does not induce the oxidation of reduced diphosphopyridine nucleotide unless an appropriate phenol is present With œstradiol-17β, or hexœstrol or diethylstilbœstrol as co-factors, the oxidation of reduced diphosphopyridine nucleotide is abolished by 0 001 *M* sodium cyanide and by catalase 50 per cent of the maximal rate of oxidation was found with a final concentration of œstradiol-17β of 8×10^{-6} *M* A free phenolic hydroxyl group is required for œstrogens to exert a carrier function In contrast to the phenolase-catalysed reactions described above, no induction period is observed when monophenolic œstrogens mediate the oxidation of reduced diphosphopyridine nucleotide in the peroxidase system Moreover, many *o*-diphenols which act as hydrogen carriers in the phenolase-dependent reactions are incapable of transporting hydrogen in the peroxidase system and inhibit the action of œstradiol-17β therein, for example, adrenalin, noradrenalin, and 3-hydroxytyramine The behaviour of phenolic œstrogens under these conditions is similar to that described for a number of simple phenols by Akazawa and Conn[21] The latter authors have pointed out the similarity between such phenol-dependent reactions and the oxidation of dihydroxyfumaric acid catalysed by peroxidase[22] They suggested that a ternary complex of peroxidase, Mn^{++} and hydrogen peroxide catalyses the oxidation of the phenol (*R*OH) by oxygen to an oxidized form (*R*O , presumably of a free-radical nature) and hydrogen peroxide The latter substance could then, by the action of peroxidase, oxidize another molecule of the phenol to the oxidized (free-radical) form Reduced diphosphopyridine nucleotide could further reduce the oxidized phenol The process can be envisaged as

$$\begin{array}{c} 2R\mathrm{OH} + \mathrm{O_2} \rightarrow 2R\mathrm{O} + \mathrm{H_2O_2} \\ 2R\mathrm{OH} + \mathrm{H_2O_2} \rightarrow 2R\mathrm{O} + 2\mathrm{H_2O} \\ \underline{4R\mathrm{O} + 2\mathrm{DPNH} + 2\mathrm{H^+} \rightarrow 4R\mathrm{OH} + 2\mathrm{DPN^+}} \\ 2\mathrm{DPNH} + 2\mathrm{H^+} + \mathrm{O_2} \rightarrow 2\mathrm{DPN^+} + 2\mathrm{H_2O} \end{array}$$

Our ability to recover œstradiol-17β unchanged from this peroxidase system is in agreement with this formulation

These experiments suggest strongly that phenolic œstrogens can transport hydrogen in virtue of the reaction phenol ⇄ phenoxy radical Electron spin resonance studies by Rexroad and Gordy[23] have shown that hexœstrol can be converted to a free-radical form(s) by irradiation It is of interest that the injection of physiological doses of both natural and synthetic œstrogens into ovariectomized rats induces enormous increases in the activity of uterine peroxidase[24]

It is a pleasure to acknowledge many valuable discussions with Drs Charles Huggins, Paul Talalay, Gerhard Closs, and the generous gifts of compounds from Drs G C Mueller and E V Jensen This work was supported by grants from the American Cancer Society, Inc

ACTIVATION AND INHIBITION OF THE ARYLESTERASE OF HUMAN SERUM

By PROF. E. G. ERDÖS, C. R. DEBAY and M. P. WESTERMAN

Mellon Institute, Pittsburgh 13, and School of Medicine,
University of Pittsburgh, Pittsburgh 13, Pa.

HUMAN blood plasma contains at least two different enzymes capable of hydrolysing phenylacetate[1,2]. One of them is a cholinesterase, the other an aromatic esterase (arylesterase)[3]. The present studies deal with arylesterase and stem from our observation that the disodium ethylenediaminetetraacetate ('Sequestrene') added to prevent coagulation in blood samples inhibited arylesterase without affecting cholinesterase activity. Since human arylesterase has been reported to be remarkably resistant to many of the usual inhibitors[2], we have supposed that further studies of the inhibition and acceleration of activity of arylesterase by selected agents would prove of interest. In particular, tests of the effects of metal ions and sequestering agents were indicated.

The activity of the enzyme was assayed with a modification of Zeller's[4] method in a Cary recording spectrophotometer at a wave-length of 2800 A. The instrument was equipped with an expanded scale (0–0.1) slide wire assembly, which greatly increased the extent of registration. The concentration of phenylacetate was 1×10^{-3} M. In the early runs of the investigation, the source of enzyme was pooled, heparinized human plasma. Later, pooled, normal human serum gave similar results. The serum was diluted 1 : 2,000 v/v; the absorption cells of the spectrophotometer contained 0.002 ml. of serum in a *tris*-hydroxymethyl aminomethane (*tris*) buffer of *p*H 7.4. At this dilution the contribution of cholinesterase to the hydrolysis of phenylacetate was found to be negligible in the sera of healthy donors. In the experiments where the effects of inhibitors or activators were tested on the cholinesterase, the source of enzyme was purified human plasma cholinesterase preparation ('Cholase', Cutter Laboratories). This preparation was void of arylesterase activity. The temperature was kept constant at 27° C. In a few control studies, the usual Warburg manometric technique or an automatic recording titrator (Titrigraph, Radiometer) gave similar results. The effect of most of the compounds on the enzyme was tested after 5-min. pre-incubation. All concentrations given in this report show the final dilution of the substance used.

It was found that the hydrolysis of phenylacetate by arylesterase increased in the presence of calcium chloride[5]. The sensitivity of the different serum samples toward calcium varied to a great extent. On the average, an 85 per cent acceleration was observed at 1×10^{-4} M concentration of calcium chloride. Ethylenediaminetetraacetate also enhances the activity of arylesterase in the lower concentration ranges. This activation changes sharply to inhibition at concentrations higher than 10^{-5} M. The enzyme was totally inhibited by 2.5×10^{-5} M ethylenediaminetetraacetate. When the sodium salt of the calcium–ethylenediaminetetraacetate complex ('Sequestrene Na_2Ca', calcium-ethylenediaminetetraacetate) was used instead of ethylenediaminetetraacetate, no inhibition was observed. On the other hand, the magnesium – ethylenediaminetetraacetate complex inhibited similarly to ethylenediaminetetraacetate. This latter effect was probably due to the fact that calcium from the system replaced magnesium in the complex. The stability constant of ethylenediaminetetraacetate with Ca^{2+} is log K = 10.59 and that of Mg^{2+}, 8.69. Another ethylenediaminetetraacetate derivative, ethylenediamine di(*o*-hydroxyphenyl acetic acid) ('Chel *DP*'), which has little tendency to co-ordinate with calcium (log K for Ca^{2+} is 1.6), did not inhibit arylesterase. In some preliminary studies, swine serum arylesterase[6] was also inhibited by ethylenediaminetetraacetate.

The results obtained with calcium prompted us to investigate the effect of other cations on the enzyme. Arylesterase was inhibited by a number of rare earth, alkaline earth and metal ions. The best inhibitor was $GdCl_{50}$ $I_{50} = 4 \times 10^{-8}$ M; the weakest, $MgCl_2$, $I_{50} = 4 \times 10^{-4}$ M. The inhibitory effect decreased in the following order: $GdCl_3$, $CeCl_3$, $LaCl_3$, $Y(NO_3)_3$, $SmCl_3$, $CdSO_4$, $HgCl_2$, $AgNO_3$, $PbCl_2$, $ZnSO_4$, $NiSO_4$, $CoSO_4$, $CuCl_2$, $MnSO_4$, $BaCl_2$, $SrCl_2$, $MgCl_2$.

Under the experimental conditions used, the most interesting feature of these series was the inhibition by low concentrations of the stable trivalent rare earth cations and by somewhat higher concentrations of heavy metals. Yttrium and the rare earth ions were about equally active, the I_{50} values falling in the 10^{-7} to 10^{-8} M range. *p*-chloromercuryphenyl sulphonic acid also inhibited the enzyme ($I_{50} = 3 \times 10^{-6}$ M). Thus, in addition to rabbit[3], the human enzyme is also sensitive to sulphydryl agents. Sodium citrate and an amino-oxidase inhibitor, 1-phenyl-2-hydrazinopropane (*JB*516), inhibited the enzyme in a relatively high concentration. The I_{50} values were 6×10^{-4} M and 2×10^{-4} M, respectively.

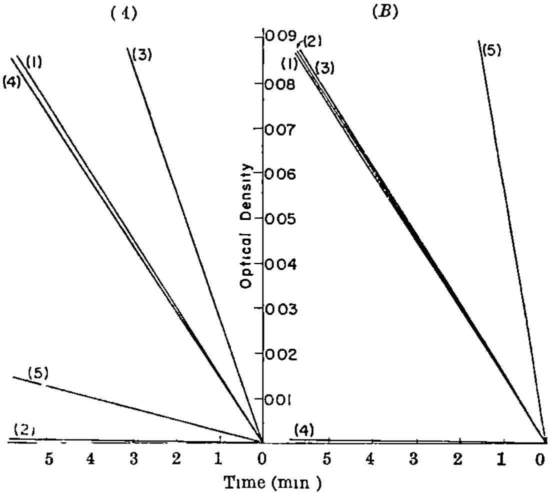

Fig. 1. Inhibition and acceleration of the hydrolysis of phenylacetate by human serum arylesterase (*A*) and by purified, concentrated human plasma cholinesterase (*B*). (1) control; (2) ethylenediaminetetraacetate 2.5×10^{-5} M; (3) calcium chloride, 1×10^{-4} M; (4) eserine, 2.5×10^{-6} M; (5) *JB*516, 1×10^{-3} M

As indicated above, 2 5 × 10^{-5} *M* ethylenediaminetetraacetate inhibited the enzyme completely Presumably this inhibition is due to removing the calcium from the enzyme molecule The acceleration by low concentrations of ethylenediaminetetraacetate may reflect a binding of an inhibitor present in the system When a 10^{-4} *M* calcium chloride solution was added soon after 5 × 10^{-5} *M* ethylenediaminetetraacetate to the enzyme, the inhibition gradually decreased and up to 70 per cent of the normal activity was restored If, instead of calcium, magnesium was added, only a negligible decrease in inhibition was observed

When a 1 10 v/v dilution of serum was dialysed against a *tris*-buffer at 4° C , the activity of arylesterase decreased 65 per cent within 17 hr , but it could be partially restored by adding calcium to the dialysed enzyme If the enzyme solution contained ethylenediaminetetraacetate in the dialysis tube, 95 per cent of the activity disappeared during the dialysis and calcium did not reactivate the enzyme This indicates that the removal of calcium from the arylesterase led to irreversible changes When the enzyme solution contained calcium-ethylenediaminetetraacetate during the dialysis instead of ethylenediaminetetraacetate, the enzyme activity remained the same as that of the dialysed control Finally, when the enzyme was dialysed against a *tris*-buffer which contained 10^{-4} *M* calcium chloride, the activity did not diminish during dialysis

Others have shown earlier that phenylacetate is hydrolysed by both arylesterase and the cholinesterase of human serum or plasma However, Fig 1 summarizes some of the differences between the two enzymes In this figure the increase in optical density is plotted against time in minutes This increase is due to the amount of phenol liberated which in turn is a function of the enzymic activity Part *A* shows that arylesterase was inhibited by ethylenediaminetetraacetate and *JB*516, activated by calcium, and unaffected by eserine[1-3] Cholase (part *B*), as expected, was inhibited by eserine The activity of cholinesterase with phenylacetate substrate was accelerated by *JB*516 and unaffected by 1 × 10^{-4} *M* Ca^{2+} and ethylenediaminetetraacetate

The results summarized in this report indicate the dependence on calcium of the arylesterase as well as the sensitivity of this enzyme toward several inhibitors A detailed account of the work with arylesterase and on the effect of *JB*516 on cholinesterase will be published elsewhere

Ethylenediaminetetraacetate, its derivatives, and the technical data were kindly supplied by Geigy Industrial Chemicals , *JB*516 by Lakeside Laboratories

REDUCTION OF TOXICITY OF CATIONIC MACROMOLECULES BY COMPLEXING WITH ANIONIC DERIVATIVES OF SYNTHETIC POLYGLUCOSES

By P T MORA, B G. YOUNG and M J. SHEAR

National Institutes of Health, Bethesda 14, Maryland

ANIONIC derivatives of synthetic polyglucoses were found[1,2] to inhibit enzyme activity of cationic proteins in consequence of the formation *in vitro* of complexes through electrostatic forces In the case of lysozyme, small amounts of salt prevented complex formation , when added after complexing, salt caused dissociation accompanied by reversal of the inhibition On the other hand, low salt concentration did not prevent complexing with ribonuclease, hyaluronidase and some other enzymes

The present communication reports experiments designed to ascertain whether the toxicity of cationic drugs of high molecular weight can be effectively blocked by analogous complexing with anionic polyglucose derivatives in the living animal, where complex formation can be affected by the salt and by the competing cationic macromolecules which are present It was found that the toxicity of a number of such materials could, indeed, be reduced Our findings extend the recent report of Higginbotham[3] that heparin, a naturally occurring anionic polysaccharide, reduced the toxicity of polymyxin-*B* in mice

In the current experiments the compounds were employed in solution in pyrogen-free water , the total volume of fluid administered was kept between 0 1 and 0 4 ml per animal Ten-week old strain *C* mice of both sexes, weighing 18–20 gm , were employed in groups of ten The mice were observed for several hours after treatment, and 24-hr survival was tabulated

The cationic substances administered at toxic level were polymyxin-*B*, protamine, streptomycin, and neomycin Toxic effects were found to be reduced by subsequent administration of the sodium salts and of the free acid forms of the sulphate and carboxyl derivatives of polyglucose Two sulphated preparations were employed, both derived from a polyglucose with a number average molecular weight of about 20,000 , the number of sulphate groups per anhydro-glucose unit was 3 and 0 6, respectively The former was preparation *H*[4] $[\eta]$ = 0 04 , the latter was preparation *D*[4], $[\eta]$ = 0 04 , the free acid form was obtained by treatment with a cation exchange resin The carboxyl derivative contained 17 per cent carboxyl (preparation *e*)[5]

Polymyxin-*B* was given in a standard dose of 0 5 mgm /mouse The mice reacted as follows within 3 min they were prostrated , respiratory embarrassment and severe convulsions developed in about 10 min , they began to die in about 20 min , those few that survived for 40 min recovered and were still alive at 24 hr

Table 1 COUNTERACTION OF TOXICITY OF CATIONIC MACROMOLECULES BY SUBSEQUENT ADMINISTRATION (5 MIN LATER) OF ANIONIC POLYGLUCOSE DERIVATIVES

Toxicity from		Counter treatment		24-hr survival (10 mice per group)
Cationic substance	Mgm / mouse	Polyglucose derivative	Mgm / mouse	
Polymyxin-*B*	0 5	—	—	2
		Sulphate *H* (acid form)	1	10

Streptomycin	8	Control	—	2
		Sulphate *H* (acid)	8	8
Neomycin	3	Control	—	4
		Sulphate *H* (acid)	6	8
			10	6

* 10 min interval between injections
† 20 min interval between injections , two mice were already dead

When polyglucose sulphate was administered 5 min after this dose of polymyxin-*B*, all the mice recovered rapidly and behaved normally within 30 min , even when the counteracting dose was delayed for 10 or 20 min . at which time some of the mice were already dead, the moribund animals recovered Similar counteraction of the toxicity of polymyxin was obtained with both the salt and the acid forms of the sulphate and carboxyl derivatives (Table 1) Analogous protection was obtained against the lethal effect of protamine However, the toxicity of streptomycin and of neomycin was only partially reduced even when larger amounts of polyglucose sulphate were used This is in line with the requirement for high molecular weight in the blocking[2] of enzyme activity

In the second set of experiments (Table 2) the polyglucose derivative was injected first, subcutaneously at the nape, while the cationic substance was given intraperitoneally In the experiments with polyglucose sulphate and polymyxin-*B*, protection against lethality and toxic manifestations was virtually complete when the interval between the injections was 2–90 min The protective effect of the carboxyl derivative was of shorter duration Polyglucose sulphate (1 mgm) yielded partial protection against the lethal dose of protamine (3 mgm)

Table 2 PROTECTION FROM LETHAL TOXICITY OF POLYMYXIN-*B* (0 5 MGM /MOUSE) BY PRIOR INJECTION OF ANIONIC POLYGLUCOSE DERIVATIVES AT A DIFFERENT SITE

Protective treatment		Time between injections	24-hr survival (10 mice per group)
Polyglucose derivative (acid forms)	Mgm / mouse		
None	—	—	2
Sulphate *H*	1	1 day	4
,,	1	300 min	3
,,	1	180 ,,	8
,,	1	90 ,,	10
,,	1	60 ,,	10
,,	1	30 ,,	10
,,	1	5 ,,	10
,,	1	2 ,,	9
,,	0 5	30 ,,	6
,,	0 25	30 ,,	5
Carboxyl	1	5 ,,	10
,,	1	10 ,,	1
,,	2	10 ,,	8

These experiments showed that polyglucose sulphate afforded protection promptly even when injected by a different route and at a site distant from that employed for the polymyxin. In addition to the direct action of the anionic derivative upon the cationic drug, it is possible that mobilized acid polysaccharide of tissue origin also may contribute to the blocking of the lethal effect[6]

Synthetic polyglucose derivatives can provide molecular model systems suitable for the study of macromolecular interactions and of the consequent biological changes Polyglucoses can be prepared different in molecular weight and in degree of branching[7] They have a highly branched, spherical structure[8], and possess numerous alcoholic hydroxyl groups suitable for graded substitution with dissociating groups For example, polyglucose sulphates with different degrees of sulphation[4] can be used to study the effect of molecular parameters (size, charge density, etc) on macromolecular interaction[1,2]

The effect of difference in charge density of polyglucose sulphates upon their potency in counteracting the lethal effect of polymyxin-*B* was also investigated Preparations *H* and *D* of polyglucose sulphate sodium salt, described above, were given as in the experiments summarized in Table 1, that is, the anionic derivative was injected 5 min after the lethal dose of polymyxin-*B* (both given intraperitoneally) Table 3 shows that the polyglucose sulphate with the higher charge density gave greater protection , for example, at the 0 1-mgm level, preparation *H* gave complete protection while preparation *D* gave none

Table 3 EFFECT OF CHARGE DENSITY OF POLYGLUCOSE SULPHATE ON COUNTERACTION OF TOXICITY OF POLYMYXIN-*B* (0 5 MGM /MOUSE INJECTED 5 MIN EARLIER)

Polyglucose sulphate sodium salt			24-hr survival (10 mice per group)
Preparation	SO_4/anhydro-glucose unit	Mgm /mouse	
—	—	—	1
H	3	0 5	10
D	0 6	0 5	9
H	3	0 25	10
D	0 6	0 25	3
H	3	0 1	10
D	0 6	0 1	1
H	3	0 05	4

Thus it has been found that such anionic derivatives of polyglucose were capable of protecting mice against a lethal dose of cationic macromolecules not only when administered first, but also by counteracting toxicity in moribund animals Furthermore, the greater their charge density the greater was their effectiveness

Cationic polyglucose derivatives have now been synthesized Their interaction with naturally occurring anionic macromolecules, and the effect of such interaction on the biological properties of the latter, are projected

QUANTITATIVE ASSAY OF COMPOUNDS IN ISOLATED, FRESH NERVE CELLS AND GLIAL CELLS FROM CONTROL AND STIMULATED ANIMALS

By PROF. HOLGER HYDÉN

Department of Histology, Faculty of Medicine, University of Gothenburg

FOR cytophysiological studies it is desirable to express results in amounts of biologically important substances per cell. The same trend seems now to exist in neurocytology for unicell analyses as is the case in electrophysiology. This article gives an account and applications of the methods used in our laboratory for the determination of substances expressed as $\mu\mu$gm. per fresh nerve cell or per volume of fresh glial cells.

Lowry[1] and his associates[2] have dissected nerve cells from thick, frozen and dried sections and have obtained excellent results. We prefer to dissect nerve cells from a cut surface through the desired locus of the fresh tissue, immersed in isotonic sucrose solution. The dissection is made free-hand under a stereomicroscope, at a magnification of 64 or 100. A stainless thread, 15 or 18μ in diameter, and sharpened to $\sim 2\mu$ (manufactured by Kanthal AB, Hallstahammar, Sweden), is used for lifting out the nerve cells into an isotonic sucrose solution. The main part of the dendrites comes with the cell (Fig. 1). Usually a very small amount of methylene blue in sucrose solution is applied to the cut surface for some seconds. The stain is taken up by the synapses, which are seen as a finely dotted border around the area occupied by the unstained nerve cell. The cell is removed before it takes up the dye, and transferred to the substrate or to the sucrose solution, where it is freed from adhering glia by gentle manipulation. Note the density of synapses on the surface of the soma and dendrites of the fresh nerve cell (Fig. 1). Nerve cells sampled in this way are used for the determination of the weight,

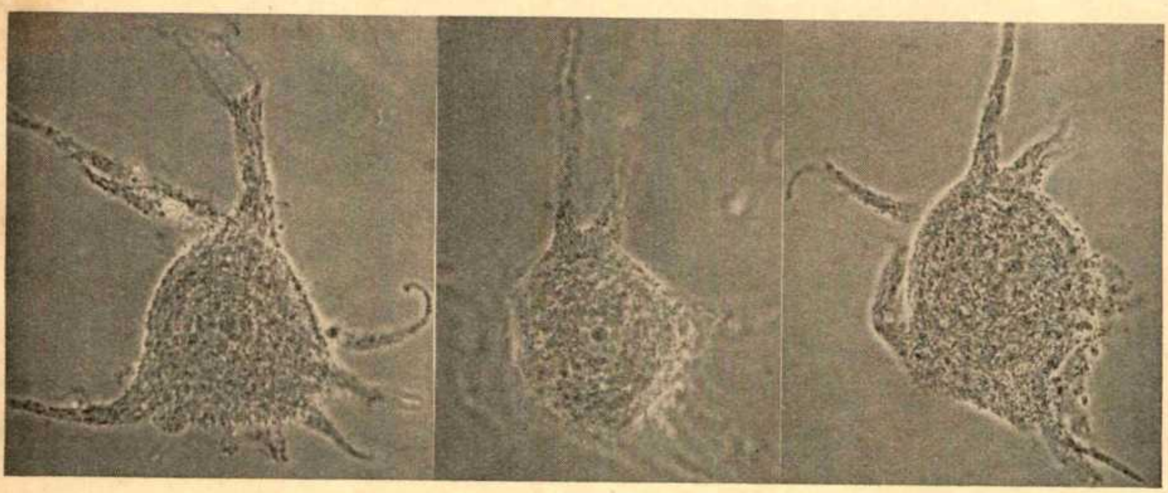

Fig. 1. Fresh nerve cells dissected out free-hand, photographed in the phase-contrast microscope. Slightly stained with methylene blue to show density of the synapses as small knobs on the surface. (× c. 200)

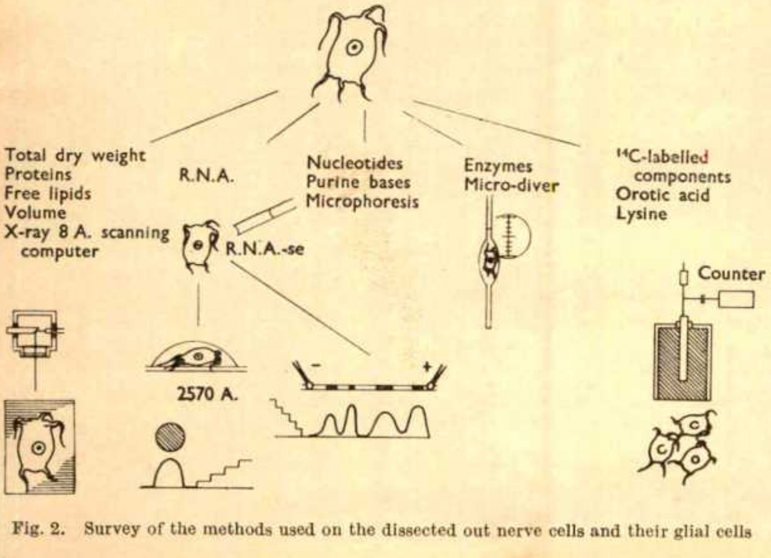

Fig. 2. Survey of the methods used on the dissected out nerve cells and their glial cells

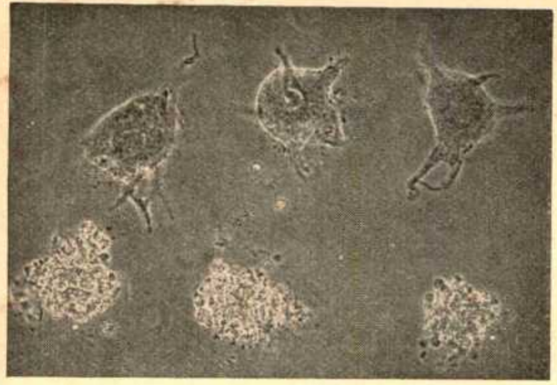

Fig. 3. Fresh nerve cells plus the neuroglial cells originally closely surrounding each cell dissected free and trimmed to the same volume as that of their nerve cell and placed in a row below the nerve cells. The collection of glial cells slightly pressed against the glass. (Phase contrast, × *c*. 30)

a protein and a free lipid fraction[3,4], ribonucleic acid[5], nucleotides[6,7], of labelled substances such as ^{14}C-orotic acid and ^{14}C-lysine[8], and of enzyme activities[9] (Fig. 2). The oligodendrocytes closely surrounding the nerve cell easily come off in the substrate and adhere to each other, and the collection may assume a spherical form. It can easily be trimmed to approximately the same volume as that of the nerve cell to which they belong (Fig. 3). The collection of glial cells is freed from larger parts of axons or dendrites.

No method hitherto described is ideal for volume determination of such an irregular cell as the nerve cell ; not even the interference microscope technique. The following method seems adequate. The total dry weight of a fresh nerve cell including the main part of the dendrites, precipitated with 1 N cold perchloric acid for 30 sec. and washed and dried, is determined by X-ray microradiography at 8–10 A. The X-radiogram is evaluated by our scanning cell analyser, which gives the weight of the cell based on up to 12,000 measurements in 4 min. The dry weight per unit volume of the nerve cell is determined on a frozen and dried section prepared in the cryostat. The volume of the fresh cell irrespective of its irregular form is the total weight divided by the mass per μ^3 of the cell material. The value for the organic material in the nucleus has been found to be as high as that in the cytoplasm.

It was found that the mass per unit volume of fresh glial cells is 0·20 $\mu\mu$gm./μ^3, which is the same as that of their nerve cells. Hence, it is possible to compare nerve cells and glial cells on the same volume basis.

Rabbits were subjected to mild rotation, through 120° horizontally and 30° vertically, 35 turns/min., for 25 min./day for 6 days. The results—those on the effect of stimulation on the nerve cells—will be published in detail elsewhere, in collaboration with Dr. A. Pigon.

Table 1. DATA FROM 80 DEITER'S NERVE CELLS, RABBIT
Values in $\mu\mu$gm. Vol. averaged 93·200 μ^3. The dry weight as $\mu\mu$gm./μ^3 was 0·23

Structure	Dry weight	Proteins	Lipids soluble in chloroform	Ribonucleic acid	Ribonucleic acid in per cent of dry proteins
Soma	20,800	16,600	4,200	1,100–1,300	7
Nucleoplasm	800	650	200	~20	
Nucleolus	100				
Nerve cell total	21,700	17,250	4,400		

The ribonucleic acid content of the oligodendrocytes expressed per volume, equivalent to that of the nerve cell, was in 15 analyses found to be approximately 100 $\mu\mu$gm., that is, ten times less than the ribonucleic acid content of the nerve cell. This is noteworthy since the number of glial cells surpasses that of the neurons by a factor of probably more than ten. Thus, it is not possible to state that ribonucleic acid found in bulk analyses of the central nervous system is that of the nerve cells, as is stated in several papers.

Table 2. EFFECT OF VESTIBULAR STIMULATION ON THE DRY WEIGHT OF DEITER'S CELLS, RABBIT
Values in $\mu\mu$gm.

Nerve cells	No.	Weight	V† (per cent)	P
Controls	50		19	0·01**
Stimulated 25 min./day for 6 days	47	24,300	31	

† V, variation coefficient.

The effect of the vestibular stimulation on these cells, second in the neuronal chain, is thus a significant increase of the dry weight of organic material. The conclusion is that the increased functional demands cause a production of intraneuronal organic material, the proteins included. This fits with earlier findings using another type of technique[10].

With measurements also on nerve cell plus same volume of glial cells altogether 500 cells have been measured.

In the controls, the respiratory enzyme activity is twice as high in the glial cells as in the nerve cell they belong to, measured on the same volume. This fits well with the results of the same enzyme activity in spinal ganglion cells and in their satellite cells[9],

Table 3. EFFECT OF VESTIBULAR STIMULATION ON THE RESPIRATORY ENZYME ACTIVITY IN DEITER'S CELLS AND IN THE SAME VOLUME OF THEIR GLIAL CELLS
Enzyme activity as 10^{-4} μl. O_2/hr./cell at 37°. Cells measured one, two or three at a time in one micro-diver

	Cytochrome oxidase				Succinoxidase			
	No. of cells	Mean	P	Ratio	No. of cells	Mean	P	Ratio
Nerve cells, stimulated	25	7·6	0·01**	1·8	57	6·0	0·001***	2·8
Nerve cells, controls	34	4·2			35	2·1		
Glial cells, stimulated	36	3·0	0·001***	0·3	41	4·0	0·6	0·9
Glial cells, controls	34	11·5			33	4·5		

and also with respect to other enzyme activities in this type of nerve cells[11]

The vestibular stimulation for 25 min /day for 6 days increased the respiratory enzyme activity of the nerve cells, belonging to the second neuron of this pathway, to a higher level Considering that the organic mass per nerve cell also increased, it may be assumed that the stimulation caused an increase in the enzyme concentration as well as activity But, at the same time, the enzyme activity in the glial cell decreased, and significantly so in the case of cytochrome oxidase It is impossible at present to interpret these results The following tentative working hypothesis may be presented Several observations support the view that the glial cells, especially the oligodendrocytes, are donors of energy or of food to the nerve cell they serve It is also known that there occurs a shift in the substrate for the metabolism of the stimulated central nervous system compared with the non-stimulated The central nervous system can furthermore burn substances other than glucose[12]

Therefore, when the nerve cells demand more energy at the increased activity, they are presumably given priority to the necessary substances by the neuroglia These cells may cut down their metabolism, which is reflected in the decreased cytochrome oxidase activity There may be an inhibiting mechanism at that terminal step, at increased neuronal activity, and the glial cells may be the cellular parts of the central nervous system which have to resort to substances other than glucose

These studies have been supported by the Rockefeller Foundation and by the Swedish Medical Research Council

VIRAL MULTIPLICATION AND CELLULAR HYPERPLASIA

By Prof COUNCILMAN MORGAN

Department of Microbiology, College of Physicians and Surgeons,
Columbia University, New York, 32

IN assessing the mechanisms whereby certain viruses cause either cellular proliferation or neoplasia, it is obviously important to determine whether replication of the virus augments or inhibits mitosis of the host cell Data bearing directly on this problem are scant Dawson[1], studying the histology of focal lesions in chicken chorioallantoic membranes infected with herpes simplex virus, reported necrosis and hyperplasia of the ectodermal cells but found that only "some of the cells show the characteristic intranuclear changes of infection" Burnet *et al* [2] confirmed these observations and noted that the proliferation followed initial necrosis of the ectoderm In addition, these authors described hyperplasia of the entodermal cells without the nuclear swelling, margination of chromatin and formation of inclusion bodies which were believed to accompany viral infection Later, Beveridge and Burnet[3] found inclusion bodies "only with great difficulty" in some chorioallantoic lesions induced by herpes simplex virus The foregoing observations, together with the fact that sterile broth, saline and emulsions or filtrates prepared from animal tissue caused proliferation of the ectoderm at the site of inoculation, led the authors to suggest that in the case of viral infection "the cell is damaged, and in response to something diffusing from the damaged cell—either virus particles or, more probably, growth stimulating substances resulting from primary damage—neighbouring ectodermal cells proliferate"

Regarding neoplasms, it has been recognized that in the human skin some verrucæ caused by viruses[4] were characterized by the presence of intranuclear inclusion bodies[4 5] and by the appearance in the electron microscope of intranuclear crystalline arrays of particles presumed to represent virus[6] Bunting *et al* [7] and Blank[8], however, noted that the cells which contained the inclusion bodies were not seen in process of division More recently, Bloch and Godman[9] reported that the bulk of these tumours was composed of "normal appearing cells" and suggested that "epidermal cells with morphological stigmata of infection, that is inclusion bodies, have lost their capacity for mitotic proliferation" These authors proposed either that the explanation by Beveridge and Burnet regarding growth-promoting substances was correct or that the viral infection was present but morphologically and cytochemically inapparent in the light microscope

The preceding studies by light microscopy were largely dependent upon the recognition of inclusion bodies as presumptive evidence for the presence of virus It has not been definitely established, however, what relationship the inclusion bodies bear to the viral particles themselves, nor is it known whether viral development is invariably accompanied or followed by the appearance of an inclusion body in the host cell Another approach to the problem of identifying virus in specific cells was provided by the fluorescent antibody technique Noyes and Mellors[10] examined sections of rabbit papillomas stained with fluorescent antibody to the antigen of the Shope papilloma virus The antigen was found to be intranuclear and generally confined to cells of the superficial keratohyaline or keratinized layers "It was surprising," the authors commented, "that practically all the cells in the proliferating layers of the papilloma contained no antigen, for the cells in these layers make the major contribution to the growth of the papilloma " They added that "there was failure to demonstrate any viral antigen in the mitotic figures of the proliferating layers" From these results the authors advanced the postulate "that the virus is present in the germinal and the proliferating cells but exists there in an early stage of development, consisting mainly of nucleic acid and deficient in protein, and therefore non-antigenic and not demonstrable by fluorescent antibody" The possibility that virus was present but in insufficient amounts to produce fluorescence could not be excluded

With the advent of techniques suited to the preparation of thin sections for electron microscopic examination, a method was at hand for visualizing viruses in host cells at sufficient resolution to detect stages in the differentiation of structural components Of the viruses mentioned above, herpes simplex virus lends itself most readily to study in the electron microscope by virtue of the fact that it grows well both in tissue cultures and in the chorioallantoic membrane Employing the latter cell system, it had been determined previously[11] that the virus develops in the nucleus where it differentiates within characteristic aggregates of granules and appears initially as a central body enclosed by a single membrane Afterwards, a second membrane is formed Particles with a central body and two peripheral membranes appear to be the completed, infectious unit Once the stages in morphological development were recognized it became possible to identify an infected cell with considerable certainty simply by the presence of viral components, even though few in number and not fully assembled into complete virus, and by the accompanying alterations in fine structure It was decided, therefore, to re-examine the relationship of herpes simplex virus to cellular hyperplasia Accordingly, a recently isolated strain (*J M*)[12] of herpes simplex virus was transferred from tissue cultures directly to chorioallantoic membranes Three and five days after inoculation the resulting focal lesions were fixed in osmium tetroxide, dehydrated in ethyl alcohol, embedded in methacrylate and cross-sectioned at multiple levels for examination in the electron microscope Thick sections were also cut and stained for orientation by light microscopy At three days there was marked hyperplasia of the ectoderm with necrosis of the superficial cells toward the centre of the lesion The mesoderm showed œdema and infiltration by inflammatory cells and there was moderate, but definite, hyperplasia of the underlying entoderm The most striking feature revealed by the electron microscope was that only a small proportion of the ectodermal, epithelial cells contained viral components or, indeed, showed any of the characteristic changes in nuclear fine structure associated with viral multiplication At five days more cells of the ectoderm were found to be infected and necrosis had extended Contrary to expectation, however, many of the cells undergoing necrosis were devoid of virus In no instance was an infected cell encountered within the hyperplastic entoderm The foregoing suggests that under the conditions of these experiments hyperplasia is not dependent upon the intracellular presence of recognizable virus or viral components

Recently, Stoker[13], studying single HeLa cells in tissue cultures infected with herpes simplex virus, found that "none of the cells which yielded virus divided" and, further, that using tissue cultures in synchronous division it was possible to inhibit mitosis by the addition of virus even 1 hr before division was to occur If it could be shown that the mode of viral development were similar both in tissue culture and in the chorioallantoic membrane, it would not be unreasonable to assume that Stoker's observations regarding the inability of infected cells to divide would apply to the latter cell system as well Consequently, detailed comparison was made by electron microscopy between the development of the *J M* strain in chorioallantoic membranes and its development in HeLa and human amnion cells grown in tissue culture No basic differences either in the manner of viral evolution or in the morphological response of the host cell were encountered Presumably, then, in the chorioallantoic membrane, as in tissue culture, herpes simplex virus prevents mitosis of the cells in which it differentiates It would appear that some factor provided by the intact host is necessary for the hyperplasia to occur, for, as Stoker[13] has pointed out, there is little evidence to suggest that this phenomenon is associated with the infection of tissue cultures by herpes simplex virus There are insufficient data to determine whether virus also interferes with mitosis of host cells in the case of tumours, but the observations cited above regarding verrucæ and the Shope papilloma are certainly consistent with such a concept In this connexion, it is of interest that the virus encountered in the Lucké carcinoma of frogs[14] closely resembles herpes simplex virus in morphology and intranuclear site of multiplication

The purpose of this communication has been to indicate that the hypothesis advanced by Beveridge and Burnet regarding the hyperplasia associated with infections by herpes simplex virus is supported by electron microscopic examination and warrants further study with the techniques currently available. Although none of the observations herein reported exclude the possibility that a masked form of the virus is operative in neoplasia, it is equally possible that in certain neoplasms a cellular product other than the virus itself stimulates mitosis The role, then, of the initiating viral infection would be to generate or liberate this product If such were the case it would explain the apparent contradiction presented by the suggestion that a virus may inhibit mitosis, on one hand, and stimulate cellular division, on the other, for the virus could multiply at a site removed from the region of cellular proliferation Moreover, the wide variation encountered in viral assays of tumours[15] could be accounted for if the stimulus for mitosis were mediated not by the virus *per se*, but by a cellular product resulting from viral infection In these circumstances the titre of virus within the tumour would not necessarily bear a consistent relationship to the extent of mitotic activity

This study was aided by a grant from the National Foundation

Friday, October 9

Institution of Electrical Engineers (at Savoy Place, London, W C 2), at 5 30 p m —Sir Willis Jackson, F R S —Presidential Address

Society for Analytical Chemistry, Biological Methods Group (at "The Feathers", Tudor Street, London, E C 4), at 6 30 p m —Discussion Meeting on "Routine Toxicity Tests in the Control of Pharmaceuticals" opened by Mr P Andrews

Saturday, October 10

Nutrition Society (at Guy's Hospital Medical School, St Thomas's Street, London, S E 1), at 10 30 a m —Symposium on "Nutrition and the Eye"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Assistant Lecturer in Agriculture—The Principal, Yorkshire (W R) Institute of Agriculture, Askham Bryan, near York (October 8)

Head of the Department of Pure and Applied Physics—The Registrar, Royal Technical College, Salford 5, Lancs (October 10)

Senior Lecturer in Mathematics, a Lecturer in Mathematics, and an Assistant, Grade "B", in Mathematics—The Registrar, Royal Technical College, Salford 5 (October 10)

Senior Lecturer (with particular interest in proteins or nucleic acids) in the Department of Microbiology—The Deputy Registrar, The University, Edgbaston, Birmingham 15 (October 14)

Reader or Senior Fellow in Biogeography in the Department of Geography, Research School of Pacific Studies, Australian National University, Canberra—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, October 15)

Lecturer in Psychological Medicine—The Secretary of University Court, The University, Glasgow (October 19)

Chair of Ophthalmology at the Institute of Ophthalmology —The Academic Registrar, University of London, Senate House, London, W C 1 (October 21)

Vandervell Chair of Pharmacology at the Institute of Basic Medical Sciences—The Academic Registrar, University of London, Senate House, London, W C 1 (October 22)

Lecturer in Civil Engineering at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, October 30)

Chair of Inorganic and Physical Chemistry in the University of Tasmania—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, October 31)

Lecturers (2) in Geography, and a Lecturer in Geology at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Hong Kong, October 31)

Technician in the Department of Physiological Chemistry to cut sections and apply standard histochemical tests in relation to a programme of research which is just being started—The Assistant Bursar, The University, Reading (October 31)

Fellow or Senior Fellow in Philosophy within the Department of Social Philosophy, Australian National University, Canberra—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, November 10)

Chair of Anatomy tenable in the Newcastle Division of the University—The Registrar, University Office, 46 North Bailey, Durham (November 21)

Chair of Geography in the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (New Zealand, December 15)

Head of the Department of Mathematics—The Registrar, The College of Technology, Ashley Down, Bristol 7

MANAGEMENT PROBLEMS IN UNDER-DEVELOPED COUNTRIES

IN a recent broadsheet which reviewed the prospects for nuclear power, Political and Economic Planning referred to the potential market in under-developed territories for a small reactor similar to that for modestly powered gas-turbine and diesel-driven generating sets. Such a reactor, if cheap, with the advantages that it can be sited where the power is needed and its fuel requirements are small, with the consequent elimination of transmission lines and high fuel transport cost, could transform areas at present undeveloped or unexploited. Whether such reactors will actually help to raise the standard of living of millions of people who are now forced to do with little or no power and to rely on inefficient fuel burning, or human labour or on animals, does not depend entirely, however, perhaps even primarily, on the ability of the scientists and technologists of the United States, Britain or the U.S.S.R.—the only three countries at present able to provide nuclear reactors for export, the knowledge of how to work them and the necessary instrumentation and servicing—to design and manufacture such a reactor at a low enough price. It depends at least as much on the provision of efficient management in the countries where the reactors are to be used.

This aspect of technical assistance has not been entirely overlooked in earlier discussions of that broad problem, but Political and Economic Planning has now examined its implications more fully in a further broadsheet, "Management and Under-developed Territories" (No. 434, June 1, 1959)*. The broadsheet is indeed primarily concerned with the problems which confront expatriate firms already operating in such countries, one after another of which are insisting that such firms must bring local nationals into their managerial and technical staff. Technically qualified nationals, however, have been very hard to find, both for lack of local technical education and for lack of the basic education necessary to acquire technical qualifications. In principle, management positions were open to anyone capable of filling them, but in practice Europe and North America have been the only sources of supply.

The broadsheet emphasizes the close connexion between political and economic factors in the under-developed territories; but to the scientist and technologist it is of special interest for its analysis of the way in which Western firms established in such countries have sought to meet this demand and of the phases of their consequent staffing policy. Factors are emphasized which should be noted by those who proceed to such countries under schemes of technical aid, no less than by those who enter the service of expatriate firms. Particularly is this true of the concluding section of the broadsheet, which discusses the influence of the political climate in such countries and the attitude that is adopted towards Western institutions and ways of doing things. The main assumption on which Western aid to the poorer countries has so far been based—that, if enough technical knowledge and capital are injected into a country which is very deficient in both, it is on the way to becoming rich and developed—is frankly challenged.

The shortage of educational and training facilities in under-developed countries, especially in Africa, has led many firms to set up their own; but this has meant both finding young men capable and willing to attend courses of higher education, and persuading young men already receiving higher education in local or European universities that the opportunities genuinely exist. Competition for the talent available locally is keen and sometimes the supply of young men of good calibre is limited by the practice of requiring scholarship holders to enter government service for a period. Moreover, a man not fully trained to the standards of a Western concern may be, by local standards, fully equipped for a senior post.

The broadsheet naturally does not enter into the problems of promotion policy which can easily arise, but these possibilities of friction have to be considered in framing a staffing policy and they are not diminished where race and class form the basis of politics, as they do now to a large extent in under-developed countries. Political pressure towards nationalization, in the sense of increasing the proportion of nationals employed, may not allow the time required to determine a wise staffing policy and to build up a tradition of fundamental values of honesty, truthfulness and loyalty, which like the readiness to assume responsibility may require to be nurtured and strengthened in different countries in different ways. While a necessary minimum of academic knowledge may be demanded of scientific or technical staff, it would be wrong to expect the same response from the graduates of such countries as from their European counterparts. Some allowance must be made for the local environment.

Nor is it simply a matter of adapting an organization to its environment. Changes in management technique may be required, and care should be taken that expatriate staff who are selecting, training and working with 'national' colleagues develop their own powers of understanding at least to the extent of being able to comprehend the mental processes of such colleagues, to assess justly their character and ability, and to assist them in their difficulties of adjustment to their job and to their European colleagues. Moreover, as *Planning* points out, the emergence of common problems of development and the disparities in supplies of trained men between countries, and the need for the parent company to keep in close touch with the problems of local companies, encourage the development of a managerial staff with wide experience outside their own countries , and this widening of opportunities for men of all races to reach positions of responsibility will probably place a practical limit upon the employment of nationals as such in any one local company

---

* *Planning*, Vol. 24, No. 434 (1 June, 1959). Management and Underdeveloped Territories. Pp. 113–130. (London: Political and Economic Planning, 1959.) 2s. 6d.

Summarizing the stages through which the staffing policies of parent firms have passed, the broadsheet notes that up to the Second World War, overseas firms were staffed largely by expatriates, who generally made careers abroad , and there was a general prejudice against business careers on the part of Western-educated nationals, even if educational facilities had been adequate for them to enter the executive ranks This was succeeded by a phase in which national talent was created where necessary, either by internal training or by the formation or support of educational opportunities outside the firm Now a third phase is emerging The arrival of the locally recruited executive has coincided with—and is partly responsible for—the rapid disappearance of the expatriate career, as distinct from the job, abroad Now, at least among the international concerns, staffing policy is developing along the lines of equipping management with international, rather than national, experience

The aim of this policy is to obtain a greater cross-fertilization of ideas through an extensive system of overseas postings during the development of the career of an executive The concept of an expatriate career is being eliminated by offering jobs abroad as an integral part of management training and promotion This new type of policy should not only improve the quality of management but also contribute to greater adaptability It clearly has implications in respect of education for management in Britain, and although it should ensure that on the Western side the weakness of rigidity is avoided, it should also be remembered that rigidity is equally dangerous where nationalism is encouraged

It is here that the broadsheet, referring to Turkey and Iraq as examples, challenges the assumption that technical aid, applied in Western manner through institutions of Western style, can alone provide all that is needed, and quotes in support Mr M Ionides's recent address, "Technical Aid the Role of the West", to the Royal Institute of International Affairs Western institutions, Mr Ionides argued, adapted to societies where the initiative comes from below, cannot fully satisfy the needs of a society where the flow of initiative is from the top downwards In particular, Western institutions are not organized to tap the immense capital resources in such countries already existing in the form of unused man-power , they can only touch the fringes where a cash-economy exists

More and more capital and technical assistance are being supplied to the centres of sophisticated Western-style economy in the under-developed countries, sharpening the contrast with the surrounding rural economy, and whetting appetites for higher standards of life Capital investment from outside, from the top downwards, cannot fill this gap and the balance of influence of the West has so far diverted the attention of these countries from their need to help to work out their own ways of filling this gap by mobilizing the reserves of labour Western-inspired ideas of industrialization naturally put the emphasis where the system works best , this attracts enterprise and initiative away from the much-needed widespread small-scale development Nor does the large-scale project which the West can provide and which most governments in these under-developed territories request, because they want to develop in the Western manner, teach the simpler methods and provide the training in them that are needed or supply where it is needed the organizing ability essential for a start It does not even provide the experience or outlook required to initiate or operate schemes which are not primarily aimed at securing profits

This is a formidable argument, and it emphasizes the close connexion between economic and political factors in the under-developed countries If it is correct, the assistance programmes sponsored by governments and international agencies may require extensive modification Deficiencies there cannot be made up by goodwill or flexibility on the part of the branches of Western industry and commerce already established in those countries Be that as it may, the prospects for the export of the small nuclear reactor should be the brighter in such a context , but the opportunities for Britain here and elsewhere will also depend on the attention given to training for management, and the quality and width of outlook and wisdom of the trained man-power which she is able to send overseas—as administrators, technologists or scientists—and whether in government or other public service or in ordinary industrial or commercial life

CLASSICS OF NUTRITION

A History of Nutrition

The Sequence of Ideas in Nutrition Investigations By Prof Elmer Verner McCollum Edited by H Bentley Glass Pp x+451 (Boston, Mass Houghton Mifflin Company, 1957) 6 dollars

The Englishman's Food

A History of Five Centuries of English Diet By the late Prof Sir Jack Drummond and Anne Wilbraham Revised, and with a new chapter by Dorothy Hollingsworth Pp 482+8 plates (London Jonathan Cape, Ltd , 1958) 36*s* net

HERE are two volumes of outstanding interest and importance It is not an exaggeration to say that each of them is indispensable to all serious research workers, and other students of nutrition

E V McCollum, now professor emeritus of biochemistry of the Johns Hopkins University, is the doyen of nutrition authorities, pre-eminent as a pioneer investigator himself, and at the same time the leading historian in this field The respect and regard in which McCollum is held throughout the world are indicated by the fact that he was among the first to be accorded the honour of election as an honorary president of the International Union of Nutritional Sciences, and that he is also to be the honorary president of the Fifth International Congress of Nutrition to be held in Washington, D.C., in 1960.

In the judgment of the present writer, an essential part of the greatness of such men as McCollum and Drummond is that they have the ability to regard science as a matter of historical development and growth, rather than as a mere catalogue of facts or a repository for items of knowledge. It is a pity that this historical outlook is not more widely encouraged to-day in our colleges and universities. All too common is the student, superficially self-satisfied, who supposes that when the lecturer turns to discuss the historical evolution of his science, rather than to present him with ready-made summaries of current information, then is the time when he can relax or quietly fall asleep. Yet the fact is that no student can hope to acquire a proper understanding of the existing teaching in his chosen sphere except by learning how the current views have come to be accepted and what is the actual foundation for them. Indeed, to the young student aspiring to become a research worker, one might go further, and say that unless he is genuinely interested in studying the bases of knowledge—that is to say, following the reasons why certain beliefs, theories or scientific explanations are held, the stages through which accepted notions have gradually travelled, in other words, their historical background—he is not likely to have the mental approach that makes a successful investigator. We may extend the argument to the teacher himself. He is a less good teacher, and a less efficient teacher, who is content to leave his student with no more than the statement that such-and-such is now the established view, and that is all there is to it. He is the better teacher, and the more stimulating teacher, who gives his pupils an explanation of the following kind: formerly certain ideas were considered well founded; but later they had to be modified in some respects because of newer knowledge and fuller understanding; and that is the reason why the presently accepted belief is so-and-so; but that nevertheless various rival opinions are often justified on any topic; and that there are always bound to remain gaps in our knowledge and room for further developments and the possibility of wider interpretations.

No doubt it is this mental approach which has served to make Prof. McCollum not only a leader in nutritional thought but also a famous experimentalist, and the instigator of so much fine work by his 'school' of colleagues and pupils. One of his own most celebrated contributions dates back to 1913–15, when he gave the first demonstration of the probable multiplicity of "rat-growth factors", and by the designations "Fat-Soluble A" and "Water-Soluble B" set the stage for the system of classifying the vitamins now familiar to all. No less influential in provoking thought and moulding opinion was his celebrated book, "The Newer Knowledge of Nutrition", the first edition of which appeared in 1918, and which may be regarded as the earliest of the modern treatises on nutrition. In a sense, "A History of Nutrition" can be considered as an up-to-date revision of "The Newer Knowledge of Nutrition". In this new work, the reader will find an impressive survey of the whole field, and one that is at the same time scholarly, well balanced, illuminated by a sound, critical judgment and a wise discrimination. The treatment is sufficiently comprehensive, in the course of its 450 pages, to cover the ground adequately and without anywhere becoming laborious, wearying or unwieldy. Much of the text is the result of careful and loving original bibliographical research by the author himself. It is certain that any future writers on nutritional history will have to turn to McCollum's new book as their starting point.

As to the new edition of "The Englishman's Food", one need say no more than that on its first publication in 1939 it immediately became the standard work on the dietary conditions of, and the food habits of, ourselves and of our ancestors during the past five centuries. Nothing covering the same ground had been available previously, or has been published since; and this second edition was sadly overdue. Miss Dorothy Hollingsworth has done her work conscientiously and well in revising the book and bringing it up to date, and has added a useful new chapter on "The Application of the Newer Knowledge of Nutrition". Unhappily, because of the increasing costs of printing, the publishers found it necessary to reduce the overall size of the book, with the result that some of the earlier chapters have had to be shortened, chiefly by the omission of quotations from historical texts, some of them of fascinating interest. Many of us will regret this; but such is the sad lot of authors to-day.

Leslie J. Harris

FLOW OF COMPRESSIBLE FLUIDS

Mathematical Theory of Compressible Fluid Flow

By Richard von Mises. Completed by Hilda Geiringer and G. S. S. Ludford. (Applied Mathematics and Mechanics: a Series of Monographs prepared under the auspices of the Applied Physics Laboratory, Johns Hopkins University.) Pp. xiii+514. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1958.) 15 dollars.

This book was originally planned by von Mises, but owing to his untimely death he was unable to complete his task. With the aid of some notes he left, Hilda Geiringer (Mrs. R. von Mises) and G. S. S. Ludford were, however, able to complete the work. The first three chapters were written by von Mises himself and the remaining two are due to the above-named authors, to whom everyone should be grateful for preserving so much of the last important work of von Mises.

The material contained in the book is intended for the research worker and the graduate student, but it should be of value to anyone making a serious study of aerodynamics. The basic theory is developed in a clear and simple way that is easy to understand. Great pains are taken to explain fully fundamental concepts and the significance of the various assumptions made in the development of the mathematical methods for the solution of certain aerodynamic problems. The concept of a specifying equation is introduced which, with the usual four equations of Euler connecting the velocity components of the flow, the pressure p and the density ρ, enables these five unknowns to be determined. The most common forms of the specifying equation are $\rho = \text{const.}$ for incompressible flow, and $F(p, \rho) = 0$ for compressible flow, where p and ρ are at all times connected by a one-to-one relation.

In scope the book is somewhat limited. Only one and two-dimensional flows are fully discussed, and in the main only problems of inviscid flow for which exact solutions have been found are considered No attempts are made to assess the practical value of these theoretical results by comparison with experiment

Chapter 1 gives the basic equations for different types of flow under various conditions and Chapter 2 is concerned with general theorems of use in the study of rotational flows, the hodograph method and the theory of characteristics Chapter 3 is devoted to one-dimensional flow and contains sections on the effects of viscosity, heat conduction, simple wave propagation, shock reflexion and shock collision A thorough presentation of the hodograph method, with a full discussion of recent advances in the theory, is included in Chapters 4 and 5 Special attention is given to the treatment of shock waves and the book ends with an article on transonic flow The main text is followed by an appendix of some forty pages of relevant and most interesting biographical and historical notes

W P JONES

THE METALLURGY OF MAGNESIUM

The Physical Metallurgy of Magnesium and Its Alloys

By Prof G V Raynor (International Series of Monographs on Metal Physics and Physical Metallurgy, Vol 5) Pp ix+531 (London and New York Pergamon Press, 1959) 75*s* net

PROF G V RAYNOR'S latest book provides the first predominantly theoretical survey of the subject of magnesium and its alloys, and it will most certainly form a valuable companion volume to those books published in recent years concerned mainly with the technological aspects of magnesium metallurgy Both students and those concerned with development in industry will welcome this authoritative work, which is presented so as to give the theory first, followed by a review with examples of the alloy systems formed by magnesium

The first part of the book (Chapters 1–7) deals with the fundamental nature of magnesium, its electronic constitution, and the effects of alloying This section contains a masterly ten-page summary of the electron theory in general, before presenting a critical account of the qualitative and quantitative studies that have been made of the electronic constitution of magnesium Magnesium is in a most interesting electronic state, and the author discusses, in a chapter on the lattice spacings of magnesium alloys, electronic interpretations of departures from Vegard's law, and lattice spacing changes due to temperature changes and to the application of tensile stress

After a description of the general alloying behaviour of magnesium, in terms of the Hume-Rothery factors of atomic size, and relative- and electro-negative valency effects, an extensive account is given of the occurrence of intermediate phases in magnesium alloys In particular, the structures of 'normal valency' compounds and Laves phases are considered in some detail, and the chapter is concluded by some pertinent observations as to why precipitation of these intermediate phases seldom leads to a high response to age-hardening in magnesium alloys

This section of the book is concluded by an account of the deformational characteristics of single crystals and polycrystalline aggregates After a fairly elementary description of edge and screw dislocations, the crystallography of slip and twinning in magnesium at room and elevated temperatures is outlined Rupture, and the development of preferred orientations, are also considered, and an account of creep characteristics concludes the chapter

The second part of the book (Chapters 8–17) describes and discusses the alloys of magnesium, considering the solute metals from the various groups of the Periodic Table in turn, stress being laid on those of present or potential importance A selected list of references is provided at the end of each chapter —the literature being reviewed up to and including 1957 Rapid reference to this part of the book would be made easier by the more generous provision of sub-headings, as the alloys in each group are discussed

A review of this nature emphasizes our ignorance of the fundamental mechanism of many technological processes, and many fields for further research are indicated The suggestion of "submicroscopic precipitates" in, for example, the creep-resistant magnesium–cerium alloys will certainly whet the appetite of electron microscopists There is, in fact, rather a dearth of photomicrographs in the book (there being only two sets), doubtless due to the high cost of their production The value of the second set of micrographs is also reduced by the absence of any supplementary information—magnification, preparation, etc

An account of the systems formed with gaseous elements or compounds concludes the review, an interesting discussion of the oxidation characteristics of the metal being included here The final chapter summarizes the influence of alloying on the mechanical properties of magnesium The book contains more than 200 diagrams—the phase diagrams being particularly well produced This robust, well-bound volume will surely grace the shelves of students and research workers alike for many years to come

J W MARTIN

BIOLOGICAL PROPERTIES OF PHENOLS OF PLANT ORIGIN

The Pharmacology of Plant Phenolics

Proceedings of a Symposium held at Oxford, April 1958 Edited by J W Fairbairn Pp ix+151 (New York Academic Press, Inc , London Academic Books, Ltd , 1959) 6 dollars , 30*s*

IT is not often that an attempt is made to present within the space of 150 pages a review of the biological properties of such a wide variety of chemical substances as the plant phenolics It can indeed be argued that such a review can be of little value because the plant phenolics comprise a miscellaneous assortment of substances having nothing in common beyond the presence of an aromatic hydroxyl group, and some may feel that the choice of subject-matter has been made even more arbitrary by the inclusion of the chapter on adrenaline, noradrenaline and 5-hydroxytryptamine, since these substances are not of plant origin and owe their characteristic pharmacological properties to the presence of an amino-group rather than to the presence of a phenolic group

Even if the fundamental pattern of this book—the proceedings of a symposium held in Oxford last year—is regarded as slightly illogical, it represents, nevertheless, an important contribution to the field of structure–activity relationships

The book begins with a concise authoritative chapter by J H Burn on adrenaline and other nitrogen-containing phenols mainly of animal origin, and is followed by another chapter, by R T Williams, summarizing what is known concerning the fate of phenolic compounds in the body In the third chapter W B Whalley discusses the toxicity of plant phenolics as a group, providing a useful introduction to the next five chapters which describe in more detail the action of specific groups of compounds J W Fairbairn, who is also the general editor, discusses the anthraquinones, and J D Biggers genistein and related compounds which exhibit œstrogenic activity and, in a separate chapter, hypericin and similar compounds that cause photo-sensitization Three chapters are devoted to the flavonoids and their effect on capillary blood flow In the first M F Lockett considers the evidence in support of the view that they act directly on capillary permeability and tensile strength, while in the other two F Deeds and J Lavollay and J Neumann present the case for indirect activity, mediated through adrenaline and ascorbic acid The last two chapters of the book deal with plant phenolics in food and wine, J Masquelier directing attention to the high bactericidal activity of some wines and E C Bate-Smith concluding the book on the reassuring note that most of the phenolic constituents of foods are fortunately pharmacologically inert

The book is well printed and free from errors Its value is greatly enhanced by the list of references given at the end of each chapter and by summaries of the discussions that took place at the symposium Most pharmacologists, organic chemists, biochemists and pharmacists will find much of interest and value in this volume F A Robinson

ORCHARD SCIENCE

Tree Fruit Production

By James S Shoemaker and Benjamin J E Teskey Pp vii+456 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd , 1959) 56*s* net

ADVANCES in plant physiology, in plant breeding, in plant protection and in the knowledge of plant toxicants, are to-day being paralleled by advances in crop husbandry and soil management, and in tree shaping and growth control The impact of these advances on commercial fruit-growing is being influenced by economic considerations While the facets are the major concern of the appropriate specialist, who may be quite ignorant of the over-all subject of pomology, the teacher of pomology, as the term is now generally understood, must be keenly aware of the progress being made in all the branches of fundamental science that affect his subject and be willing and able to incorporate the new knowledge in turn into his teaching and demonstrations

With specialist fruit-crop research stations in many parts of the world now more or less well staffed and equipped, new knowledge, supposedly new knowledge or old knowledge recapitulated is being published so plentifully as to embarrass alike both teacher and taught From time to time experienced teachers give us the benefit of their selection from among this wealth of material and, if they are competent teachers and are critical in their selection, the result is a good book

Dr Shoemaker is such a teacher, and this book, written in collaboration with Dr Teskey, bears evidence of a wide-ranging but careful selection of subjects (there are more than 800 references, the majority of them within the past 20 years) and a commendable compression of the essential material , an 11-page double-columned index makes for easy reference Text-books on husbandry are difficult to illustrate, and this one is no exception , line drawings and diagrams, like those on grafting, are clear and good , photographs of plantations and many field operations, like picking and pruning, do not reproduce well

The authors have covered apples, pears, cherries and plums, all of which interest us in the British Isles Peaches, apricots, nectarines and quinces should interest our Western and Southern European neighbours, and citrus fruits are also the concern of the countries bordering the Mediterranean sea The authors were not catering for this wide public but aimed at producing an up-to-date guide to current orchard and fruit plantation practice for use in Canada and America Nursery practice, site selection and modification, planting considerations and varieties for particular purposes are all discussed, together with tree nutrition, pest and disease control, soil and plantation management and harvesting as well as handling and storage There is a special chapter on the cultivation of dwarf apples and pears, evidently in response to demands from students for information on this subject For a long time European growers have been particularly expert in controlling tree size and yield, and American growers may face many difficulties in adapting European methods to their needs

Though essentially written for students this book contains much that will interest fruit growers and their advisors in many parts of the world

SCHIZOPHRENIA

Schizophrenia· Somatic Aspects

Edited by Derek Richter Pp viii+181 (London and New York Pergamon Press, 1957) 40*s* net

Chronic Schizophrenia

By Thomas Freeman, John L Cameron and Andrew McGhie Pp xi+158 (London Tavistock Publications, Ltd , 1958) 21*s* net

A New Approach to Schizophrenia

By Julius I Steinfeld Pp 159 (London Hutchinson Medical Publications, Ltd , 1958) 21*s* net

SCHIZOPHRENIA is a major cause of disability in most parts of the world In countries for which statistics are available it constitutes approximately half the chronic population of mental hospitals Almost one in every hundred persons is fated to suffer from the disease, and the majority, particularly the men, break down in the second and third decades of life The wastage of human life and the amount of suffering and social dislocation it causes are probably greater than that due to any other single disease The International Congress of Psychiatry held two years ago was devoted wholly to this subject Its deliberations served largely to bring home the failure to achieve any substantial advance in knowledge of its causation since the condition was first described by Kraepelin and later further defined by Bleuler.

These three books reflect three of the commoner types of theoretical approach adopted in the vast literature on the subject: the organic or somatic approach, the psycho-analytic and the eccentric.

The monograph edited by Derek Richter contains a number of essays dealing with the present state of knowledge in relation to the anthropometric aspects and the electroencephalographic, neuropathological and endocrinological observations. There is a study of metabolic changes in recurrent schizophrenia, one on the effects of drugs introduced into the cerebral ventricles, a paper on the therapeutic effects of drugs and on the symptoms induced by mescaline which are at times scarcely distinguishable from those observed in schizophrenics. One paper attempts to reconcile the observations suggesting that a mutant gene is the primary cause with those that imply that environmental causes are of some importance. The picture of present knowledge that emerges is scarcely encouraging. Schizophrenics differ as a group from normal controls in respect of body build and in relation to a whole range of biochemical tests. There is some evidence that histologically demonstrable changes occur in some parts of the brain. The schizophrenic also responds abnormally to a wide range of drugs. But all these changes are without specificity and the degree of overlap with normal control groups is so great for all anomalies that they are rendered useless for purposes of diagnosis. In many instances uncertainty remains as to whether we deal with manifestations of causal agents, with effects of the disease or the results of long periods of institutional care. Moreover, with the possible exception of Gjessing's celebrated work on disturbances of nitrogen metabolism in the very small group of cases of periodic catatonia, none of the differences found has been so far successfully exploited to advance knowledge in relation to ætiology, prognosis or classification. The one hard fact which shines clear and constant through this nebulous matrix of data is that the hazard for developing schizophrenia in the sib of a schizophrenic is some ten times that for a member of the general population; for his child sixteen times, for a dizygotic twin some thirteen times and for a monozygotic twin between seventy and eighty times as great. Although its significance remains unclear, the recently demonstrated difference in the chance of being admitted to mental hospital with schizophrenia in the different social classes has been already confirmed in a number of countries and promises to be an equally clear and consistent observation.

The dismally slow rate of progress along organic lines has led some workers to throw up the sponge and to devote their energies to the uncovering of meaningful associations in the mental life of the schizophrenic. The theoretical framework for this kind of endeavour is usually provided by one of the schools of psycho-analysis. The stringent controls considered essential for scientific inquiry to ensure that findings are not interpreted in accordance with preconceived theory are often regarded as inapplicable or irrelevant. The psychoanalytic exploration and treatment of schizophrenia has in recent years attracted enthusiastic adherents; it had previously been considered therapeutically useless.

The book by Dr. Freeman and his colleagues deals with observations and treatment inspired by psycho-analytic teaching and carried out in two groups of chronic schizophrenic patients. They concur in the view expressed by Federn that the essential psychological disturbance produced by this disorder is a weakening of the functions of the ego leading to a breakdown of its boundaries and failure to differentiate between self and non-self or environment. Variations in the form of the disease are attributed to the degree of ego function. The disorders of thought, affect and volition and the disturbances of perception characteristic of the schizophrenic are all considered to stem from the change in the experience of the self. Although this is regarded as the essential psychological disturbance, the problem of ætiology is left open. The therapeutic programme based on these findings is directed towards ego-building, which includes fostering closer and more durable relationships between patients and nurses, efforts to communicate at the patient's own archaic level, and, on the assumption that stimulation of the body enhances awareness of the self, such things as stroking the face and making a ceremonial of bath-time. The effects of these measures on ward atmosphere and on individual patients are said to have been gratifying but no clear analysis of the results is given.

Exploration of the inner life of the schizophrenic is of value as a form of inquiry, and a premature insistence on quantitative data in a field such as this can prove stultifying to new ideas. Some Continental psychiatrists who do not subscribe to psycho-analytic teaching have testified to the beneficial effect exerted by this kind of endeavour when initiated in a mental hospital where formerly the predominant influence was the so-called "objective" psychiatry, the adherents of which at times unwittingly treated the patient almost as if he had been an inanimate object.

However, the scientific merit of theories cannot be decided by pragmatic considerations. The breakdown of ego boundaries here described as the source of all psychological disturbances in schizophrenia is equally applicable as a metaphorical description for the mental disturbances in delirium, dementia, dreaming and depersonalization, which are quite different phenomena. Moreover, a very large number of unifying explanations have now been proposed, all claiming to be illuminating for the understanding and efficacious in the treatment of schizophrenia. Thus Dr. Steinfeld's book states that oral frustration in infancy is the root cause. Excessive hunger in early life over-strains the vegetative mechanisms, which may then remain in a state of high catheris through life. He has more than a suspicion, for reasons not made explicit, that in carcinomatosis similar mechanisms may be at work.

As in other fields of scientific inquiry, insights, and 'intuitive leaps' in psychiatry have to be treated with respect—those of others no less than one's own—which is precisely why none deserves serious consideration until its relevance and heuristic value have been objectively demonstrated so far as possible.

Many observations cited in the first book suggest that the slow progress of scientific inquiry in this field may be partly due to the heterogeneity of schizophrenia. Recent genetic, clinical and epidemiological data show promise for discovery of the natural lines of division between the different variants in the syndrome. When this has been achieved, progress in the definition of causal agents in schizophrenia, whether psychogenic or physiogenic, is likely to be accelerated.

Martin Roth

The World of Learning 1958–59

Ninth edition Pp xiii+1139 (London Europa Publications, Ltd , 1958) 130*s* net.

THE ninth edition of the "World of Learning", which is now well established as a valuable guide to scientific, cultural and educational institutions throughout the world, follows the pattern of its predecessors, but is considerably enlarged, due to the world-wide expansion of scientific and technological research, and to the recent foundation of many universities and technical colleges in the relatively undeveloped countries

The first section, devoted to Unesco, describing its aims, programmes, organization and finance, is followed by a short account of the work and structure of the International Council of Scientific Unions and other international organizations, together with brief statements of their objects and the names of their principal officers

The remainder of the book is divided alphabetically into the various countries of the world (by their names in English) The arrangement of entries for Great Britain—which occupy 86 pages—affords an indication of the scope of the work learned societies and professional associations , research institutes , libraries , museums and art galleries , universities and university colleges , centres of adult and technical education , schools of art, music and dramatic art , agricultural colleges , and education trusts In general, the entry for each institution includes its address, the names of its leading officials , and for each university a complete list of professors is given Where applicable, the titles of any publications issued by the body concerned are also listed The entry for the U S S R , which occupies 38 pages, lists the members of the Soviet Academy of Sciences and the heads of its various departments and research organizations Forty-one Russian universities are listed, with their faculties, but the names of their professorial staffs are not given , a long list of the very numerous institutions of higher education and research of the Soviet Union are, however, included The largest single entry, comprising 190 pages, relates to the United States of America

There is an alphabetical index of institutions, but none of persons, mentioned in the book

Handbook of the Rubi of Great Britain and Ireland

By the late W C R Watson Pp xi+274 (50 figures) (Cambridge At the University Press, 1958) 63*s* net

PROFESSIONAL systematists tend to be superior about brambles and batologists, partly because, in Britain at least, batology has been primarily an amateur study, but perhaps more particularly because the *Rubi* refuse to comply with orthodox ideas, and, like slum children in a respectable neighbourhood, are a perpetual affront to the dignity of those who value orderliness and correct behaviour It was perhaps vain to hope that Mr Watson's long-awaited monograph would finally set the seal of respectability upon this sprawling and troublesome group, but the opinions of one who studied the brambles assiduously for more than forty years must be given careful consideration Every line of this admirably produced monograph bespeaks seriousness of purpose, integrity and industry, and the wealth of Watson's knowledge is testified time and time again throughout the book, though perhaps most strikingly in the introductory pages What a pity the author did not live to publish a separate and more elaborate essay on brambles and bramble classification, for it must be confessed that his generalizations and *obiter dicta*, though perhaps controvertible, are vastly more intriguing than his detailed and somewhat desiccating descriptions of the three hundred and ninety-one species said to occur in Britain Admittedly everything possible has been done, in keys, descriptions and illustrations, to convey the author's mature conclusions to the reader, but language and art have their limitations, and the fond hope that the book will "furnish the means of identifying every native species met with" is perhaps a shade too optimistic The unenlightened sees only one blackberry , the observant possibly half a dozen, but only the specialist, with twenty or more years experience behind him, can hope to recognize the majority of the species included in this book , and then—who knows—the specialist may wish to add a further hundred species of his own to the British list, for one suspects that *Rubus* species, like parallel lines, can be extended to infinity R D MEIKLE

Annual Review of Entomology

Vol 4 Edited by Edward A Steinhaus in association with Ray F Smith Pp viii+467 (Palo Alto, Calif . Annual Reviews, Inc , 1959 Published in co-operation with the Entomological Society of America) 7 dollars

A REVIEWER always likes to imagine editors and authors feverishly scanning his Olympian judgements and then departing to brood on the error of their ways While experience must inevitably destroy this pleasant picture, it is gratifying to notice the present coincidence Volume 4 of the "Annual Review of Entomology" fulfils almost entirely the critical requirements suggested in reviews of the previous volumes in these columns Thus we have a volume broadly based not only in subject-matter but also in the geographical distribution of its contributors , a review which includes several papers on subjects at the 'growing-points' of entomology—insect physiology, ecology and control—and finds space for one or two on the borderline of other sciences, such as the role of insects as disease vectors In fact, it would be a dull entomologist indeed who could not find something of interest or profit in the present volume

If this standard is maintained then critical interest can be transferred to a higher level , although in the present volume the general concept is good, a few of the individual treatments fall short of this standard and degenerate into the 'card-index' type of review Review articles of the highest quality must not only present a selection—for in these days that is all it can be—of the literature but must also strive to produce some stimulating and if possible enlightening synthesis from it

In matters of detail the present volume is as well produced as its predecessors and at last each article has a bibliography in alphabetical order , the index is good, although several misprints and incorrect page numbers appear here

But these are small matters compared with the solid value and interest of this volume , the Entomological Society of America, which this year terminates its financial obligations to the "Review", must be congratulated on bringing into being a work which, on present standards, will be of great value to every entomologist P T HASKELL

RADIOCARBON DATING OF PREHISTORIC WOODEN TRACKWAYS

By DR H GODWIN, F R S , and DR E H WILLIS
University Sub-department of Quaternary Research, Botany School, Cambridge

THE purpose of building corduroy tracks is to avoid detours, and prehistoric examples of these wooden structures have been preserved by continuous water-logging It is not surprising, therefore, that increased wetness of climate should have caused many former routes to be flooded, and have induced first the construction and then the preservation of wooden trackways Thus there is an expectation that, were it possible to determine the age of a number of trackways, their ages would be grouped at distinct periods of climatic deterioration

Corduroy tracks, however, have not been studied typologically, and apart from axe-marks on the timber and the chance of associated archæological finds, they have been very difficult to date, until the advent of pollen-analysis, and, more recently, of radiocarbon dating

Both techniques have been applied to the problem of dating several of the wooden trackways revealed in recent years by peat-cutting in the derelict raised bogs of the Somerset Levels Some of these have been described already[1], and descriptions of others are being prepared for publication (*Phil Trans Roy Soc Edinburgh*) They run between the Mendip and the Polden Hills and the low islands that project through the intervening flat lowlands of the Glastonbury Levels

The six Somerset trackways so far dated, and also certain associated wooden platforms, all occur at a comparable stratigraphic horizon in the bogs This is at the surface of a very dark, highly humified *Sphagnum–Calluna–Eriophorum* peat, and its junction with a *Cladium–Hypnum* peat The lower peat is indicative of the growth of heather-clad bogs receiving water only as rain or snow, in a condition of arrest or slow growth their gentle convex surfaces could easily have been traversed on foot and offered little obstacle to passage across the levels The overlying *Cladium–Hypnum* peat by contrast points unmistakably to flooding by calcareous water from the big catchment area of the Mendips and Polden Hills Such flooding imposed very circuitous routes between one hill ridge and another and the evidence suggests that the wooden trackways were built in consequence of the flooding and that their preservation was ensured by its continuance

Several of the trackways were also shown to be close to the same pollen-analytic zone-boundary, and upon this evidence it was suggested that the tracks were probably built about the transition between the Bronze Age and the Iron Age This supposition was strengthened by the occasional discovery upon the timber of the markings of the small thick axes of Late Bronze Age type, and by the recovery of two bronze spearheads at comparable stratigraphic levels, one of the Late Bronze Age and the other of late Middle Bronze Age

Radiocarbon dates have now been obtained for the wood of the trackways and also of the peat in which they are embedded The assays were made with carbon dioxide at 2 atmospheres pressure in a copper proportional counter of about 2-litres volume[2]

Table 1 DATING OF WOOD FROM TRACKWAYS*

		Years B P
Q 52	Meare Heath track (Bulleid's)	2840 ± 110 2850 ± 110
Q 39	Shapwick Heath track (Foster's)	2470 ± 110
Q 308	Westhay track (Sandford's)	2800 ± 110
Q 306	Blakeway Farm track	2600 ± 110
Q 7	Vipers track (Dewar's A)	2520 ± 110
Q 312	Vipers track (Dewar's A)	2630 ± 110
Q 313	Nidons track (Dewar's B)	2585 ± 120
Q 311	Vipers platform	2410 ± 100 2640 ± 110

* For fuller information on the provenance of the samples see ref 3

It will be seen that these all lie between 450 and 900 B C , which is certainly Late Bronze Age in this part of Britain The datings are supported by those of the associated peat

Table 2 DATING OF PEAT ASSOCIATED WITH TRACKWAYS

		Years B P
Q 53	Meare Heath track—subjacent peat	3230 ± 110
Q 44	Shapwick Heath track—subjacent peat	3310 ± 110
Q 309	Blakeway Farm track—subjacent peat	2790 ± 110
Q 316	Nidons track—peat at track level	2590 ± 120
Q 318	Nidons track—subjacent peat	2642 ± 120
Q 319	Nidons track—subjacent peat	2482 ± 120
Q 317	Nidons track—superjacent peat	2628 ± 120

Whereas the results from Nidons track suggest close contemporaneity between the track itself and adjacent peat, at the other sites the greater age of the underlying peat supports the field evidence that some erosion or wastage of the peat surface had occurred before the trackways were constructed

As long ago as 1906 a monoxylous boat had been recovered from the bog deposits near Shapwick Station, but under conditions that did not allow any dating or reference to a stratigraphic horizon It was apparent that it could not have been embedded while the bogs were covered by heather and cotton-grass and it seemed likely that it related to a substantial flooding period The curator of Taunton Castle Museum, where the boat is now preserved, kindly provided enough wood for the following radiocarbon assay

Q 357 Shapwick boat 2305 ± 120 years B P

It will be seen that this assay places the boat within the Early Iron Age, so that it is younger than the wooden trackways and indeed corresponds in age with the *Cladium–Hypnum* peat of the major flooding episode of this time

There is a good deal of evidence in various parts of north-western Europe that about 600 B C there was in progress a change of climate towards increased rainfall and lower temperatures It has been made the boundary between the Sub-boreal and Sub-atlantic climatic periods , it is an important pollen-zone boundary and is often marked by 'recurrence-surfaces' in peat bogs In view of the likelihood that this climatic change was also widespread in Britain it is interesting to append the radiocarbon dates from three further wooden trackways that we determined.

Table 3. TRACKWAYS OUTSIDE SOMERSET

		Years B.P.
Q 310	Fordy—Little Thetford, Cambs.	2560 ± 110
Q 77	Brigg, Lincs.[5]	2552 ± 120
Q 68	Kate's Pad, Pilling, Lancs.	2760 ± 120

It was already known from associated prehistoric finds that the Brigg trackway clearly belonged to the Late Bronze Age to Early Iron Age transition. Pollen-analytic evidence and a single sherd from the Fordy trackway had already suggested a similar age for that structure. It is now strikingly evident that indeed all the trackways belong to the one archæological period.

Of course, prehistoric trackways were built at other periods than this, and the Groningen laboratory has dated an Irish example as follows:

GRO 272 Corlona, Co. Leitrim 3395 ± 170 years B.P.

None the less, the consistency of the English results is striking and strongly underlines the importance of carefully recording and dating these unregarded prehistoric monuments.

A NEW FOSSIL SKULL FROM OLDUVAI

By Dr. L. S. B. LEAKEY

Coryndon Museum, Nairobi

On July 17, at Olduvai Gorge in Tanganyika Territory, at Site *FLK*, my wife found a fossil hominid skull, at a depth of approximately 22 ft. below the upper limit of Bed I. The skull was in the process of being eroded out on the slopes, and it was only because this erosion had already exposed part of the specimen that the discovery was possible. Excavations were begun on the site the following day and continued until August 6. As a result, an almost complete skull of a hominid was discovered. This skull was found to be associated with a well-defined living floor of the Oldowan, pre-Chelles-Acheul, culture.

Upon the living floor, in addition to Oldowan tools and waste flakes, there were the fossilized broken and splintered bones of the animals that formed part of the diet of the makers of this most primitive stone-age culture. It has not yet been possible to study the fauna found on this living floor; but it can be said that it includes birds, amphibians, reptiles such as snakes and lizards, many rodents and also immature examples of two genera of extinct pigs, as well as antelope bones, jaws and teeth.

It is of special importance to note that whereas the bones of the larger animals have all been broken and scattered, the hominid skull was found as a single unit within the space of approximately one square foot by about six inches deep. Even fragile bones like the nasals are preserved. The expansion and contraction of the bentonitic clay, upon which the skull rested and in which it was partly embedded, had resulted, over the years, in its breaking up into small fragments which have had to be pieced together. The bones, however, are not in any way warped or distorted. A large number of fragments still remain to be pieced together.

This very great difference between the condition of the hominid skull and that of the animal bones on the same living floor (all of which had been deliberately broken up) seems to indicate clearly that this skull represents one of the hominids who occupied the living site; who made and used the tools and who ate the animals. There is no reason whatever, in this case, to believe that the skull represents the victim of a cannibalistic feast by some hypothetical more advanced type of man. Had we found only fragments of skull, or fragments of jaw, we should not have taken such a positive view of this.

It therefore seems that we have, in this skull, an actual representative of the type of 'man' who made the Oldowan pre-Chelles-Acheul culture.

This skull has a great many resemblances to the known members of the sub-family of Australopithecinae. Some scientists recognize only one genus, namely, *Australopithecus*, and treat Broom's *Paranthropus* as a synonym; others consider that the demonstrable differences are of such a nature that both genera are valid. Personally, having recently re-examined all the material of the two genera, in Johannesburg and Pretoria, I accept both as valid.

The Olduvai skull is patently a member of the sub-family Australopithecinae, and in certain respects it recalls the genus *Paranthropus*. In particular, this is the case in respect of the presence of the sagittal crest, the great reduction in the size of the canines and the incisors, the relatively straight line of these teeth at the front of the palate, the position of the nasal spines and the flatness of the forehead. In certain other characters, the new skull resembles more closely the genus *Australopithecus*, for example in respect of the high cranial vault, the deeper palate and the reduction of the upper third molars to a size smaller than the second, all of which are features to be found in *Australopithecus* but not in *Paranthropus*.

The very close examination and direct comparisons which I have personally made in South Africa have convinced me that, on the basis of our present state of knowledge, the new skull from Olduvai, while clearly a member of the Australopithecinae, differs from both *Australopithecus* and *Paranthropus* much more than these two genera differ from each other.

I am not in favour of creating too many new generic names among the Hominidae; but I believe that it is desirable to place the new find in a separate and distinct genus. I therefore propose to name the new skull *Zinjanthropus boisei*. This generic name derives from the word 'Zinj', which is the ancient name for East Africa as a whole, while the specific name is in honour of Mr. Charles Boise, whose constant encouragement and financial help ever since 1948 have made this and other important discoveries possible. I would also like to acknowledge the generous help received, from time to time, from the Wenner-Gren Foundation and the Wilkie Trust.

The following is the preliminary diagnosis of the new genus and the new species :

Zinjanthropus gen. nov. :

Genotype : a young male with third molars not yet in wear and sutures relatively open, from *FLK* I, Olduvai.

A new genus of the Hominidae, sub-family Australopithecinae, which exhibits the following major differences from the genera *Australopithecus* and *Paranthropus* :

(*a*) in males a nuchal crest is developed as a continuous ridge across the occipital bone ;

(*b*) the inion, despite the great evidence of muscularity, is set lower (when the skull is in the Frankfurt plane) than in the other two genera ;

(*c*) the posterior wall of the occipital bone rises more steeply to form, with the parietals, a very high-vaulted posterior region of the skull ;

(*d*) the foramen magnum is less elongate and has a more horizontal position than in *Australopithecus* (in the crushed skulls of *Paranthropus* it is not possible to be quite sure of the plane of the foramen magnum) ;

(*e*) the presence of a very massive horizontal ridge or torus above the mastoids. This is much more marked than the normal type of supra-mastoid crest ;

(*f*) the mastoids are more similar to those seen in present-day man, both in size and shape ;

(*g*) the presence of a strong wide shelf above the external auditory meatus, posterior to the jugal element of the temporal bone ;

(*h*) the shape and form of the tympanic plate, whether seen in *norma lateralis* or in *norma basalis*. In this character the new skull has similarities with the Far Eastern genus *Pithecanthropus* ;

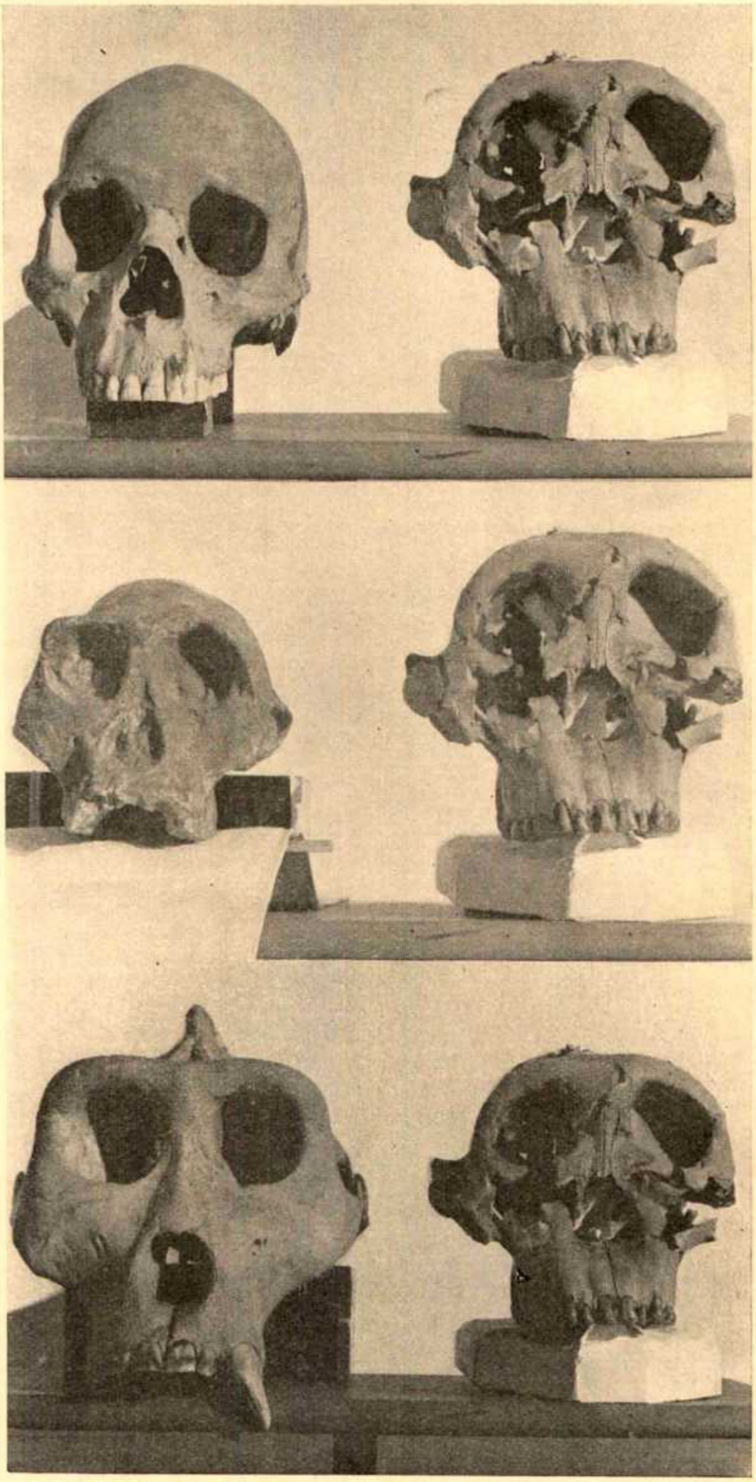
(*i*) the very great pneumatosis of the whole of the mastoid region of the temporal bones, which even invades the squamosal elements ;

(*j*) the massiveness of the jugal element of the temporal bone relative to the total size of the temporal bone ;

(*k*) the way in which the parietals rise almost vertically behind the squamous elements of the temporal before bending over to become a dome ;

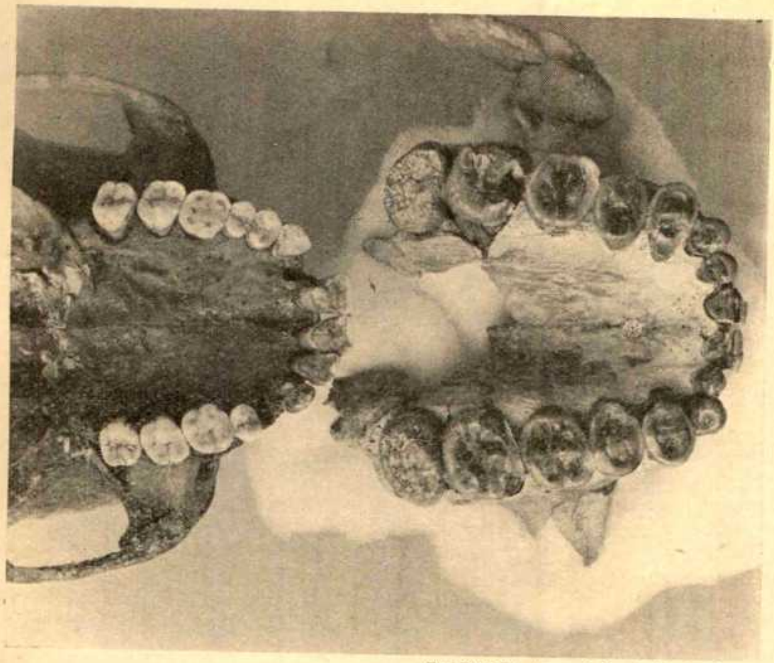
(*l*) the relative thinness of the parietals in comparison with the occipitals and the temporals ;

(*m*) the very prominent and keeled anterior margin of the crests on the frontal bone for the anterior segment of the temporal muscles in the region of the post-orbital constriction (even the most



Des Bartlett–Armand Denis Production

Fig. 1. *Above* : The new skull compared with the skull of an Australian aboriginal. Note the very long face, the architecture of the malar region, the unusual nasal bones, the torus above the mastoid, the sagittal and nuchal crests. *Middle* : The new skull compared with a cast of the most complete adult of *Australopithecus*. Note the difference in the size and shape of the face, the shape of the tympanic plate, the low position of the inion, the huge mastoid, as well as the difference in the shape of the malar region and the supra-orbital area. *Below* : The new skull seen next to that of a gorilla



Des Bartlett–Armand Denis Productions

Fig. 2. The palate of the new skull compared with that of an East African native

muscular male *Paranthropus* exhibits nothing comparable) ;

(*n*) the very unusual position of the nasion, which is on the most anterior part of the skull, instead of being behind and below the glabella region ;

(*p*) the very great absolute and also relative width of the inter-orbital area, with which may be associated the shape of the nasal bones, which are much wider at the top than at their inferior margin ;

(*q*) the whole shape and position of the external orbital angle elements of the frontal bone ;

(*r*) the very deep palate which is even more markedly like that of *Homo* than in *Australopithecus*, and is quite unlike the form seen in *Paranthropus*, except in respect of the more or less straight canine-incisor line which has already been commented on, as a character recalling *Paranthropus* ;

(*s*) the conformation of the malar-maxillary area of the cheek. In all known members of the genera *Australopithecus* and *Paranthropus* there is a buttress of bone which runs down from the malar towards the alveolar margin of the maxilla in about the region of the fourth premolar ; in *Zinjanthropus* this buttress is wholly absent and the form of architecture of this region is that which is found in *Homo* ;

(*t*) the very great area of muscle attachment on the inferior margin of the malars ;

(*u*) the relatively greater reduction of the canines in comparison with the molar–premolar series than is seen even in *Paranthropus* ; where it is a marked character.

Zinjanthropus boisei sp. nov.

A species of *Zinjanthropus* in which the males are far more massive than the most massive male *Paranthropus*. The face is also excessively long. Males have a sagittal crest, at least posteriorly. Upper third molars smaller than the second.

The above is only a preliminary diagnosis of the genus *Zinjanthropus* species *boisei*. It is recognized that, if and when further material is found, the diagnosis will need both enlarging and possibly modifying.

The whole question of generic value is one which is relative. There are some who maintain that *Australopithecus* and *Paranthropus* are not generically distinct, and who will wish to treat *Zinjanthropus* as a third, but less specialized, species of a single genus ; but the differences seem to be too great for this.

I must now turn to the absolute and relative geological age of the new skull. As stated earlier, *Zinjanthropus* comes from Olduvai Gorge, about 22 ft. below the upper limit of Bed I. It was found in association with tools of the Oldowan culture, on a living floor and with associated fauna.

In the past it has been customary to regard Olduvai Bed I as a part of the Middle Pleistocene, not differentiating it from Bed II. During the last few years, however, detailed excavations at sites *BK* II, *SHK* II and *HWK* II have shown that there is a constant and well-marked break between the top of Bed I and the base of Bed II. It is incidentally on this clearly defined land surface that Chellean Stage I living sites are found.

There has also been found a great deal of new faunal evidence, and it is now clear that the fauna of Olduvai Bed I is the same as that of Omo, and that both are generally of the same age as that of Taungs. In other words, it is now necessary to regard Olduvai Bed I as representing the upper half of the Villafranchian and not the lower part of the Middle Pleistocene. So far as relative dating is concerned, it now seems clear that in the Far East the Djetis beds belong to the Middle, rather than to the Lower, Pleistocene, so that the new Olduvai skull would be older than the oldest *Pithecanthropus*.

In South Africa, the deposits at Taungs and Sterkfontein are now regarded as belonging to the upper part of the Lower Pleistocene ; they must therefore be regarded as generally contemporary with Olduvai Bed I. The Makapan beds are a little younger, in all probability, while Swartkrans is of Middle Pleistocene age, as are the upper beds at Sterkfontein which are now yielding stone tools.

With the Taungs child, therefore, and the *Australopithecus* fossils from the lower beds at Sterkfontein, the new find represents one of the earliest Hominidae, with the Olduvai skull as the oldest yet discovered maker of stone tools.

The following approximate measurements will indicate the size of the new specimen.

Length from inion to glabella	about 174 mm.
Greatest breadth at supra-mastoid torus	,, 138 mm.
Greatest breadth of brain case on squamosal element of the temporal bones	,, 118 mm.
Height (in Frankfurt plane) from basion to a point vertically above it in the sagittal plane	,, 98 mm.
External orbital angle width	,, 122 mm.
Inter-orbital width	,, 32·5 mm.
Post-orbital width	,, 88 mm.
Palate-length from front of incisors to a line joining back of third molars	,, 84 mm.
Palate-width at second molars	,, 82 mm.
Palate-width at third premolars	,, 62 mm.
Length of molar–premolar series	,, 72 mm.

Teeth measurements :

*M*3 : 21×16 mm. ; *M*2 : 21×17 mm. ; *M*1 : 18×15·5 mm. ; *PM*4 : 18×12 mm. ; *PM*3 : 17×11·5 mm. ; *C* : 9·5×9 mm. ; *C*2 : 7×7 mm. ; *C*1 (both damaged but about 10×8 mm.).

ASPIRIN AND ALGESIMETRY

By DR. C. V. WINDER
Parke, Davis and Co., Detroit 32, Michigan

ASPIRIN relieves mild natural pain of various causes and locations. It is reasonable to expect, therefore, that it should raise the minimal noxious stimulus required for an experimental nociceptive response in animals or for experimental pain perception in man. This has been realized in several laboratories with satisfactory validity; but experiments have failed. Success and failure by respective procedures exist side-by-side in the same laboratory without explanation. We, like others, have repeatedly failed to demonstrate an effect of intraperitoneally administered aspirin on the threshold amount of mechanical pressure on a rat's tail required to induce squeaking[1]. We have succeeded, on the other hand, in showing an effect by the same route on the threshold intensity of radiant heat, applied to the back of guinea pigs, that is required to elicit a twitch of the skin muscles[2]. The success is often repeated[3]; and the dose of aspirin required is in appropriate relationship to doses of morphine or meperidine required in the same procedure—all high, relative to human doses.

Magnitude of Experimental Anti-nociceptive Effect

The greatest rise in nociceptive threshold caused by increasing intraperitoneal doses of aspirin in the guinea pigs is about 30 per cent[2,3]. Similarity of this magnitude to that originally reported by Wolff *et al.*[4] for the rise in radiant thermal threshold for pain perception in man is only coincidental. When the guinea pigs were given aspirin by stomach tube instead of intraperitoneally, even large, toxic doses caused no more than 10–15 per cent rise in threshold[5]. When Wolff's group adopted a less biasing experimental design with placebo control, a change bearing no relationship to the change in route of administration in guinea pigs, the ceiling of effect in man also became 10–15 per cent[6]. The factors responsible for the larger intraperitoneal effect in guinea pigs remain unknown.

A similar small effect of aspirin was observed in dogs by Andrews and Workman[7], using the same stimulus-response system afterwards used in the guinea pigs, and later by Richards[8]. Eagle and Carlson[9] tabulated a very small effect of aspirin on the rat's threshold to mechanical stimulation of the tail. Hart[10] and Bonnycastle *et al.*[11] obtained definite effects in rats with respective modifications of the D'Amour–Smith[12] procedure (tail flick in response to radiant heat). Gibson *et al.*[13] reported significant effects of the sodium salt of aspirin on the threshold strength of electrical stimulation of the rat's rectal mucosa required to induce squeaking. Deneau *et al.*[14], working with experimental deep pain of calf muscles in man, exhibited a clear-cut 10–15 per cent rise in the threshold stimulus associated with aspirin administration. Benjamin[15] showed that aspirin significantly delays the time when pain terminates work being done by the human forearm deprived of circulation, and presented results suggesting that more intensive work with less precise procedures would also show aspirin effects of statistical significance.

Thus, it seems inescapable that a small and subtle anti-nociceptive effect of aspirin can be demonstrated in the laboratory with brief noxious stimulation not obviously associated with inflammation, though the conditions required are poorly understood.

Site of Experimental Antinociceptive Effect

Cook and Bonnycastle[16] could find no effect of aspirin on spinal reflexes. They[11] found that relatively large amounts were required in the chronic spinal rat, as contrasted with the intact rat, to influence the tail-flick response to radiant thermal stimulation. It is inferred that at least a portion of the acute experimental anti-nociceptive action of aspirin, perhaps varying among successful experiments, occurs at neural mechanisms above the spinal level.

In this connexion, it is classical knowledge that nociceptive responses are potentially complete at the spinal level, especially in lower species, but that in the intact animal they are under constant control of a balance of active inhibitory and excitatory influences from high levels (for example, ref. 17). Unfortunately, since Irwin *et al.*[18] pointed out that the tail flick and the skin twitch are like other nociceptive responses in this respect, many writers have spoken of these two responses as "merely spinal reflexes"[18] even in the intact animal. Winter and Flataker[19] and Bonnycastle and Cook[11,16] have commented on this error.

Possible Role of Neurological Summation

During early work on twitch in the skin of the guinea pig, we found[2] that sensitivity of the threshold stimulus intensity to morphine varied significantly with the area and duration of the radiant heat stimulus. We selected as near optimal a large area (730 mm.^{2}) and an intermediate duration (4 sec.), determining threshold intensity as the dependent parameter. With this in mind, I suggested six years ago[20] that use of a pattern of stimulus characteristics emphasizing spatial or temporal neurological summation might in some way be a factor of success in demonstration of an anti-nociceptive effect by aspirin. The area of stimulation employed by Wolff's group[6] ordinarily was about 80–310 mm.^{2}, and presumably that of Andrews and Workman[7] was similar. Hart[10] prewarmed the rat's tail subliminally, thus providing a likelihood of temporal summation. Bonnycastle[11] pointed out the probable importance of his less intense and more prolonged stimulus. Deneau's[14] pressure-cuff affected a large muscle mass. Gibson's[13] rectal electrode was relatively large. Benjamin's[15] uncirculated forearm was a considerable mass of tissue.

This will recall the well-known opinion of Wolff's group[6], based on work with liminal 'pricking pain', that pain sensation is neurologically unique in lacking the property of spatial summation. Rather, these workers' results would seem to indicate a very pronounced central occlusion of a smaller liminal field by a larger one[2], reflecting at once the poor local sign of pain and a very efficient central convergence of excitation. Even so, spatial facilitation manifests itself near the limen, either for the subjective sensation[21] or for the nociceptive response[2].

Insufficiency of Central Anti-nociceptive Action Alone

However real, a central neural action so small and subtle as that of aspirin seems inadequate by itself to account for the efficiency with which the drug relieves natural pain. Goetzl[22] came to this conclusion on viewing his own negative experimental results with aspirin together with older work. Now there are more positive kinds of evidence.

During the past two decades many compounds of miscellaneous structure have been reported in the pharmacological literature to possess experimental anti-nociceptive potencies in animals more or less superior to that of aspirin but inferior to that of codeine. Many of these have been tested clinically; but none has been generally accepted. Two such compounds with which we have worked were more powerful anti-nociceptives in guinea pigs than aspirin, and, by contrast with aspirin, were significantly though not strongly anti-nociceptive in rat tail-pinching experiments (α-piperidyl-3,4-dichlorophenylacetic acid, monohydrochloride, and 1-(1-piperidyl)-1-cyclohexanecarboxamide, monohydrochloride; synthesized by E. M. Jones and P. J. Ehrlich (1950–51); evaluated for anti-nociceptive action by J. Wax, J. Lyon, S. Kaprielian, V. Burr, M. Been and C. V. Winder (1950–54).) Yet, in natural human pain, both were significantly ($P = 0.05$) inferior to aspirin, if, indeed, effective at all[23].

The history of salicylamide is instructive. The anti-nociceptive action of this old compound is sufficiently greater than that of aspirin to be demonstrable in many laboratories. Yet the drug's analgetic efficacy, long in doubt before the recent attention it has enjoyed, is now again in serious doubt[24]. Derivatives of salicylamide even more potent as anti-nociceptives in animals also have failed as yet of clinical acceptance, at least one being significantly[25] and another fairly probably[26] less effective than aspirin in natural pain.

It is therefore now reasonably clear that a degree of experimental central anti-nociceptive action somewhat greater than that of aspirin is not, by itself, predictive of clinical analgesia. It is conceivable, though unsupported, that the quality of central action by aspirin differs from that of many other kinds of agents in such manner that, even though small, it could account for relief of natural pain.

One consequence of this working attitude is that many of us need no longer be so concerned with boxfuls of experimental compounds having no more anti-nociceptive action than, say, salicylamide, excepting those for which evidence can be found of some adjunctive action that could potentiate a small anti-nociceptive effect in the relief of pain.

Adjunctive Anti-preinflammatory Action

Returning to aspirin in search of some adjunctive property, one sees most prominently the drug's well-established anti-rheumatic effect, a fairly specific anti-inflammatory action in the acute phases of rheumatic diseases. It could be a suppression of some rather early process—a preinflammatory process—in the course of reaction by tissue to injury. The same process could lead both to stimulation of pain endings and, eventually, to frank inflammation. It could be a process more or less common to early tissue injury associated with various kinds of natural pain. It would probably take longer to develop than the duration of most experimental noxious stimuli.

The hypothesis that a peripheral anti-preinflammatory property is essential in the relief of natural pain by aspirin gains stature on again considering salicylamide. Doubt concerning the analgetic efficacy of this agent, in spite of supra-aspirin anti-nociceptive potency, parallels doubt concerning its anti-rheumatic efficacy[24b]. A complementary test of the hypothesis is provided by aminopyrine. With a similar order of anti-nociceptive potency, the unquestioned analgetic efficacy of this drug parallels its unquestioned anti-rheumatic efficacy.

Harris proposed several years ago[27] that the pain-relieving effect of aspirin could be explained entirely in terms of a peripheral anti-inflammatory action. The present hypothesis differs in considering, rather, an anti-preinflammatory action as an adjunct which, as may become apparent later on, is probably not entirely sufficient by itself.

Adjunctive Actions of Other Kinds

It is likely that other poperties of aspirin sometimes contribute to its ability to relieve mild pain. In pre-equilibrium phases of certain febrile states the antipyretic effect may relieve muscle soreness in part via reduction of muscle tonus.

The hypothetical necessity of an anti-preinflammatory action in aspirin or aminopyrine for significant relief of natural pain would, correlatively, require that another kind(s) of adjunctive action be identified in the acetanilid group. Neither acetanilid nor acetophenetidin is clearly antirheumatic in ordinary clinical doses[28], nor is N-acetyl-*p*-aminophenol known to be, yet all are considered able to relieve mild pain[24a,28]. However, all have the underlying anti-nociceptive action. Acetanilid and acetophenetidin are, perhaps, more potent than aspirin in this respect[22]. N-acetyl-*p*-aminophenol, the main metabolic intermediary of both[29] and perhaps substantially responsible for their anti-nociceptive action[30], is about equally potent[31]. Moreover, all are antipyretic[28,31] and, in addition, seem to possess a pattern of sedative and relaxing properties[4,28] that could be importantly adjunctive to the anti-nociceptive action[4].

Insufficiency of Adjunctive Properties Alone

Analgetic efficacy in the acetanilid group thus suggests an underlying importance in a mild analgetic agent of anti-nociceptive action, small and subtle though it may be. Mere absence of pyrexic malaise and muscle tension, or of anxiety, or presence of mild sedation, is not *per se* generally analgetic.

The case of phenylbutazone indicates that anti-rheumatic potency alone is insufficient for prediction of general analgetic efficacy. This drug is now well known to be the most potent anti-rheumatic agent outside the cortisone group, yet there seems to be no firm evidence for utility in relieving pain except in grossly inflammatory diseases. Correspondingly, though large intravenous doses were anti-nociceptive[32], we have been unable to detect such action at sublethal intraperitoneal doses in guinea pigs, or at a fourth the LD_{50} of the drug intraperitoneally in rats[33]. Fewer rheumatologists are now referring to phenylbutazone's 'analgetic' action, and more to its anti-inflammatory action.

Lack of known usefulness of cortisone-like agents as general-purpose analgetics may not be pertinent These glucocorticoids possess a different kind of peripheral anti-inflammatory action[34], perhaps not impinging so specifically on particularly early reactions to tissue injury that lead directly to stimulation of pain receptors

Thus, it has been our working hypothesis for the past few years that the small, central, anti-nociceptive action of aspirin or aminopyrine, though necessary, is not sufficient by itself for mild analgesia , but is effectively potentiated (?) by a peripheral anti-preinflammatory action related to non-steroidal anti-rheumatic action which, however, is also insufficient alone

One interesting implication is an explanation of the old and growing clinical popularity of mixtures of codeine with aspirin, or of aspirin and acetophenetidin The anti-nociceptive effects of the two or three agents would be additive The more general sedative effects of codeine and acetophenetidin would, perhaps, add The combined anti-nociceptive effect would amplify the peripheral anti-preinflammatory effect of the aspirin and the sedative effect of the codeine and acetophenetidin The end clinical action of the combination of drugs might be somewhere between addition and multiplication of the individual drug effects

A Laboratory Model of Pre-inflammation

For several years we have been studying the influence of drugs and chemicals on development of erythema on albino guinea pigs following exposure to ultra-violet energy[34] , a procedure first employed by Wilhelmi[32,35] This experience has strongly influenced development of the foregoing hypothesis

In a standardized procedure wherein the erythema is developed 2 hr after exposure, divided-dose pretreatment with a typical non-steroidal anti-rheumatic agent delays the appearance of the erythema in a proportion of animals depending on dosage Significantly effective divided doses of various agents in the experiment closely approach daily anti-rheumatic doses in the clinic, on a body-weight basis

Aspirin and aminopyrine are effective in this test they are anti-rheumatic, anti-nociceptive and analgetic Salicylamide is not effective , it is doubtful as an anti-rheumatic, and, in spite of easily shown anti-nociceptive action, is doubtful as an analgetic The two supra-aspirin experimental anti-nociceptives mentioned earlier that were found ineffective as clinical analgetics[23] were not effective in this test[36] Phenylbutazone is most potently effective , it is most potently anti-rheumatic, yet not clearly anti-nociceptive and not, apparently, generally analgetic The acetanilid group presents the same problem discussed earlier These agents are not effective in the ultra-violet erythema test at dose-levels that would be tolerated , they are not usefully anti-rheumatic , but, nevertheless, their anti-nociceptive action apparently provides an underlying basis for mild analgesia, perhaps essentially aided by a more general action on the central nervous system

The ultra-violet tissue injury sets off a pre-inflammatory phenomenon amenable to influence by non-steroidal anti-rheumatic agents Presumably it is related to a pre-inflammatory phenomenon in various painful tissue states which these same agents influence when, provided they also have some central anti-nociceptive effect, they relieve pain

Cortisone-like agents do not influence the erythema[34c], have different kinds of effects on inflammatory processes, and are neither anti-nociceptive[19] nor known to be generally useful as analgetics The more potent analgetic agents from codeine upward do not delay the erythema and have no specific anti-rheumatic effect Their pain-relieving actions are central and are associated with sufficiently robust experimental anti-nociceptive effects so that there is no great difficulty in comparing them in the laboratory in terms of acute, non-inflammatory pain

One can only speculate on the nature of pre-inflammatory processes induced by noxious tissue states, leading to stimulation of pain endings and eventually to frank inflammation, and susceptible to agents like aspirin It is conceivable that some clarification might come from work now being done in several laboratories on activation of proteases and/or globulins, formation of kinins, release of potassium, etc [37]

More Complete Laboratory Models of Natural Pain

If the ordinary experimental noxious stimulus is, perhaps, too brief to allow development of the pre-inflammatory state upon which aspirin seems to have an essential component of its action, then it is natural to consider having this state pre-established as a part of the eventual total stimulus We were therefore gratified to note a description by Randall and Selitto[38] of a laboratory model of inflammatory pain—measured pressure applied to the inflamed and œdematous foot of the rat One is reminded of Schumacher's[39] earlier work on the effect of aspirin on experimental pain thresholds of inflamed human skin

Using the inflamed foot, Randall and Selitto found sodium salicylate, acetophenetidin, N-acetyl-*p*-aminophenol, and phenylbutazone effective in raising the threshold pressure required for a nociceptive response It is somewhat discouraging that aminopyrine was not significantly more effective than sodium salicylate —a deviation from clinical experience It is interesting and more understandable that acetophenetidin and N-acetyl-*p*-aminophenol were only a half to a quarter as potent as sodium salicylate, even though they were more potent central anti-nociceptives as measured with the normal, uninflamed foot This agrees with the absence either of anti-rheumatic and anti-erythemic (ultra-violet) effects of these two agents at tolerated dosage, or of any obvious means for reflexion of their adjunctive sedative properties in the results Also, it is gratifying that phenylbutazone was only slightly more potent than sodium salicylate, and would thus be predicted to have general analgetic utility, if any, only at doses much larger than can safely be employed clinically for the anti-rheumatic effect This agrees with the present lack of clinical evidence of general utility as an analgetic, and with absence of clear anti-nociceptive action at subtoxic doses (*supra*)

Randall and Selitto[38] suggest a liability in their model that we believe may be inherent in any involving œdema[34a]—a liability to indirect effects from vascular disturbances caused by the agent on test It will be interesting to study the properties of a model in guinea pigs combining the relatively non-œdematous[34c] ultra-violet inflammation and the acute, wide-area radiant heat stimulus[2,3]

Recently, mice injected intraperitoneally with appropriate amounts of phenylquinone[40] or acetic acid[41] have been observed to 'writhe'[40] or 'stretch'[41] repeatedly and for long periods The phenomenon is suppressed by suitable doses of aspirin or aminopyrine, as well as by the more potent central analgetics The stimulus, presumably noxious, differs in two important respects from those considered hereto First, it is applied to a larger tissue surface, potentially bringing into play a much broader pattern of neurological convergence Secondly, it is present for a longer time, at once providing possibilities of temporal neurological summation and of maturation of preinflammatory processes In terms of the present thesis, any or all of these factors would improve sensitivity to agents like aspirin or aminopyrine

High doses of acetophenetidin required to suppress writhing in one laboratory[40], and of salicylamide in another[41], recall again the poor activity of these agents as anti-rheumatics or anti-erythemics (ultra-violet) and suggest that the writhing stimulus leans to some extent on a pre-inflammatory component Discrepancy between the two laboratories in effectiveness of sodium salicylate is puzzling Suppression of the writhing by a variety of chemicals and drugs[41,42] renders the phenomenon rather enigmatic at present

It may be that, with increasing attention to matters like extensity, duration and quality of stimulus, as well as to higher-level neurological conditioning[43], research workers will gradually resolve the differences between experimental and natural pain so long and vigorously emphasized by Beecher[44]

CHANCE AND PROBABILITY

If the fundamental concepts of mathematical probability and their role in statistical theory are still subject to sharp controversy after three centuries of discussion by the acutest minds, we can scarcely expect that the concepts of psychological probability, born within the past decade, should already have found general acceptance It is not indeed clear to everyone where mathematical probability ends and where psychological probability begins, if it is justifiable to separate them at all The papers presented at a session of Section J (Psychology) during the York meeting of the British Association at least shared the view that the study of psychological probability unquestionably offers important opportunities for research into hitherto unexplored realms of mind and behaviour The three papers presented were "Wishful Seeing in a Gambling Situation", jointly by Dr John Beloff and Mr Kenneth Warwick (Queen's University of Belfast), and read by the former , "Chance and Uncertainty", by Dr W Mays (University of Manchester), read in his absence by Dr D McMahon , and "The Psychology of Luck", by Prof John Cohen (University of Manchester)

The paper by Dr Beloff and Mr Warwick was devoted to an experimental study of 'perceptual autism', an expression coined by Prof Gardner Murphy in 1947 to refer to those subjectively distorted changes in perception which have the effect of gratifying the observer's needs—in other words, wishful seeing. The context of the experiments was a type of gambling situation. As a point of departure they took various investigations by Murphy and his colleagues designed to establish the autistic phenomenon and they discussed the criticism that the observations could be explained in terms of the familiar notions of 'expectancy' or, alternatively, in terms of 'response availability' without postulating a special autistic mechanism. Thus if a hungry man, on being shown an inedible object, says that it is something edible, it does not follow that he says so because he sees it as such but merely because he would naturally be thinking of things to eat. Dr. Beloff's experiments were designed to rule out these alternative explanations.

Three distinct experiments were conducted. In the first the subject had to guess which of four possible visual stimuli would appear in a brief tachistoscopic exposure. Before each exposure the subject was told that a square (with a cross inside) would be shown with one of the sides missing, and he had to guess which one it would be. He was given money with which to bet on his guess. On the autistic hypothesis the guesses should tally with the bets on a statistically significant number of occasions.

In this first experiment there were two series of presentations, one random and one biased. In the random series, the subject presumably had no 'reason' to believe that a particular card was more likely to appear at a given trial, whereas in the biased series it was experimentally possible to distinguish between what the subject 'expected' and what he 'wanted' to appear. There was a significant autistic effect, in spite of marked individual differences in patterns of response. This led Dr. Beloff to suggest that autism is a feature of personality and, in this sense, akin to optimism.

In order to meet the possible objection that this outcome was due to 'response availability', the second experiment introduced a new series which required the subject to bet on the card which he expected *not* to appear, and to forfeit his bet if it did. The reward series again revealed an autistic effect but not the penalty series, the bet-guess correspondence being at chance-level.

In the third experiment a further attempt was made to ensure that the hypothesis of 'expectancy' could be eliminated by depriving the subject of the power of deciding which of the four cards was to be rewarded. The subject now won his bet if the stimulus corresponded to a particular counter drawn at random in advance of the exposure. This experiment seemed to show clearly that "once desire is divorced from expectancy by introducing an *arbitrary* system of rewards and penalties, the autistic effect no longer operates". Without denying that emotions may influence perception autistically, Dr. Beloff concluded that there is no need to assume a special central determinant, as proposed by Prof. Murphy.

Dr. Mays's paper discussed certain logical and psychological issues arising in the study of probability in general. He began by referring to Venn's views expressed in his "Logic of Chance" (1876) and passed on to a more detailed criticism of Prof. S. E. Toulmin's contribution to an Aristotelian Society symposium on probability in 1950. As to Prof. Toulmin's question of the meaning of 'probability', Dr. Mays stated: "the answer is probably very little, since it refers to a generalized situation, not always specifiable by concrete operations". In his view, Prof. Toulmin under-estimated the extent to which adult thinking is permeated by technical ideas deriving from games of chance.

Dr. Mays stated that psychologists had studied the pragmatic understanding of probability from two points of view: that of methodology and that of concept formation. He thought that the initial impulse to study subjective probability had come from experiments on extra-sensory perception, and suggested that descriptions of the way people behave in experimental probability situations ought not to be taken as a guide to rational behaviour, that is, as ethical norms, which subjective probability, in the sense used by Ramsey and Savage, is evidently meant to be.

Much of Dr. Mays's paper took the form of a critical résumé of the views of certain psychologists, notably Goodfellow and Piaget. The main feature of Piaget's work, he declared, is to take "the abstract calculus of probabilities as an objective standard of mature behaviour, and deviations from it (the so-called illusions) as a mark of immaturity". The concept of 'chance', according to Piaget, is not an intellectual intuition, but has to be learnt; since the child endeavours to find a causal factor in everything he observes, he cannot apply the notion of equi-possibility of probability situations. The child's notion of probability, in Piaget's view, only appears when he has built up a system of logical operations enabling him to contemplate possibilities (in terms of combinations and permutations) beyond what actually happens.

Dr. Mays believes that there is little to be said in favour of the belief in a special type of subjective probability postulated to cover what he described as "really an amalgam of emotional attitudes, intellectual systems, etc.", an approach which reminded him "of the instinct psychologists and the Aristotelians who postulated a new type of instinct for every form of behaviour".

Prof. Cohen placed the study of luck in the context of psychological probability. The belief in luck, he suggested, originated in the attempt to master life's uncertainties. As societies become more civilized their uncertainties do not diminish. Hence the idea of luck survives with full vitality. The examination of luck formed part of a systematic series of studies, initiated at Manchester in 1952, into those forms of thought and behaviour which characterize states of uncertainty: choice, estimation, prediction, inference, risk-taking, and decision-making generally; and the method of investigation was at once experimental and developmental. He ventured to make two inferences from his earlier inquiries which had a bearing on the present one. First, the idea of 'randomness' is alien to the human mind, which is essentially pattern-seeking or, in more general terms, engaged in an implicit or explicit search for meaning. Secondly, there is evidence that our minds act as unwitting 'computers' and, under certain conditions, an analogy can be drawn between quasi-additive and quasi-multiplicative operations in psychological probability and the fundamental properties of mathematical probability.

Prof. Cohen then considered the meaning of 'luck' in terms of observed usage, principally in the twofold sense of 'unearned advantage' and 'fortuitous intervention'. He illustrated the survival of beliefs in luck by reference to the fact (as he had found) that young and old alike still have their lucky colours, days and numbers Moreover, people are believed to have stores of luck which can be depleted and replenished, and there is evidence that women felt themselves to be luckier than men

Prof Cohen was mainly concerned to describe experimental demonstrations of the effect of a belief in luck on expected performance and achievement Thus, a subject could estimate realistically his likely performance at any given task This estimate could then be compared with other estimates of his likely performance if he thought he would be (*a*) lucky, (*b*) very lucky, (*c*) unlucky, (*d*) very unlucky From a variety of experiments of this kind it seemed that, within a given range of tasks, to be lucky signified an expected improvement in performance of some 10 per cent, and to be very lucky, of 20 per cent Unluck meant an expected deterioration of 30 per cent and very bad luck anything up to 80 per cent

An allied effect of the belief in luck could be measured in terms of the proportion of attempts in which the subject expected to succeed at particular tasks varying in level of difficulty Here, too, the pattern of realistic estimates could be compared with the pattern of estimates of success with varying degrees of expected luck and unluck Psychological probabilities derived in this fashion revealed that when tasks are of comparable subjective difficulty the patterns of estimates of expected performance bear a striking mutual resemblance Furthermore, a pessimistic under-estimation of one's capacity appeared when the task seemed subjectively easy and an optimistic over-estimation when it seemed hard A generalization of particular interest could be embodied in the formula

$$\psi_{l}^{p} \quad + \quad \psi_{\bar{l}}^{1-p}=1$$

where ψ represents the psychological probability, p the *a priori* probability of success, and l (and $\bar{l}$) the degree of luck (or unluck) to which the original estimate relates What is conveyed by this formula is the empirical observation, based on many experiments, of the quasi-additive character of psychological probabilities Suppose, for example, that the *a priori* probability of a subject's success at a task is 0 1, and that his corresponding psychological probability, if he thinks he will be very 'lucky', is 0 6 , then when the *a priori* value of success at a similar task is 0 9, his psychological probability of success if he thinks he will be very 'unlucky' turns out to be approximately 0 4 The additive property appears when the values of ψ are derived from estimates made after as well as in advance of performance

A different analysis was employed by Prof Cohen to measure the frequency with which we think good or ill fortune will befall us In his experiments, the estimate of performance which is regarded as most realistic is expected by the subject to occur on some 52 per cent of the occasions, the lucky (or unlucky) outcome on some 17 per cent and the very lucky (or very unlucky) outcome on some 7 per cent These experiments, Prof Cohen believes, shed light on the basis of our aspirations For in everyday life we are often governed by unrealistic considerations, and what we are, in fact, prepared to undertake may depend basically on what we imagine we should achieve if we were lucky or unlucky The range and pattern of psychological probabilities might justify the assumption of a sort of inner 'standard deviation' of judgment

Prof Cohen also spoke at some length of social repercussions of a belief in luck, particularly as a stabilizer in allaying socio-economic envy, and in discouraging initiative , and he referred to the 'magical' significance of the practice of disparagement, both of self and of others In conclusion, he drew a parallel between individual and cultural psychological probability, in that the phenomenon of pseudo-subjective dependence (or the Monte Carlo fallacy) has its analogue in the cyclic, as contrasted with the linear, conception of time and history which characterizes traditional and archaic cultures

COAST EROSION AND ACCRETION

IT is almost true to say that , despite the full and interesting reports of the Royal Commission on Coast Erosion (1907–11), little effective action on the coasts of Britain was taken until the severe flooding of 1953 occurred A Departmental Committee was then appointed under the chairmanship of the late Lord Waverley, and in 1954 made two relatively short reports containing a number of recommendations Three of them are particularly relevant to this article No 10 reads "that steps should be taken to ensure proper co-ordination of researches Recourse might well be had for this purpose to the constitution of two consultative and advisory standing committees There should be close co-operation on research matters between British and Dutch scientists, engineers and Governments" Recommendations 2 and 3 emphasized the necessity of research into "the behaviour and suitability of vegetation for use on sand, shingle and other material adjacent to the sea", and "the urgency of research into the movements of beach material, off-shore banks and related coastal problems" Thus the discussion organized by Sections E (Geography) and K (Botany) at the recent British Association meeting at York was particularly relevant

The two standing committees referred to have been formed, and the one devoted to sea defences is that most concerned with this article The other is primarily concerned with tidal and oceanographical matters The sea defence committee, under the chairmanship of Mr E A G Johnson, of the Ministry of Agriculture, Fisheries and Food, has already made three reports to the Ministers concerned (Agriculture, Fisheries and Food, Housing and Local Government, and the Secretary of State for Scotland) The committee is very alive to the physical and ecological problems affecting our coast, and Mr G Cole, who acts as secretary, was one of the speakers at York It is the first time in Britain that such complete co-ordination on coastal problems has been attained Mainly through the personnel of the committee very close contact is maintained with the Hydraulics Research Board, the Nature Conservancy, the Building Research Station (in connexion with sea-wall and sea-bank construction), and the universities Since, too, radioactive and other tracers are becoming more and more significant in coastal work, there is also a close link with Harwell

In practice the erection of sea defences of one kind or another is the work of engineers, either consultants or those connected with river boards, or local or national authorities But all who are interested in the coast are concerned among other matters with the source, supply and maintenance of beach material, and with the holding of dunes and the formation of marsh Experience has shown all too often that indiscriminate building of groynes and walls may have very serious effects in other places Since the natural protection of much of our coast is a good beach, it is all important to study how it is to be maintained Careful surveys made by members of the Department of Geography at Nottingham showed that it took 5 or 6 years before the Lincolnshire beaches were restored fully to the level they reached before the 1953 flood scoured them almost completely In many cases it is possible to assume with a fair degree of certainty that a beach is fed by lateral transport If this is interfered with at some locality sites to leeward are bound to suffer But there are places, for example Scolt Head Island, where it is not unreasonable to assume that new material comes more from offshore than alongshore This matter of offshore supply is one that is frequently debated, and one that perhaps can be finally settled only by tracer or aqualung methods Already some useful results based on observations by divers have been obtained at Scripps Institute of Oceanography and a beginning has been made in Britain by the physiographic unit of the Nature Conservancy Careful observations by trained men in water down to a depth of perhaps 100 feet may help very greatly in many shore problems These more recent methods of approaching the question of supplies of beach material do not in any way mean that the type of studies already in use should be discontinued Far from it, they should be pursued vigorously, and to 'know' a beach implies a long study. It may sometimes be necessary in building defences to act hurriedly, and it may happen that the result is successful In general, however, the study of a beach over a period including all types of weather likely to act upon it is desirable Moreover, it is also valuable to be able to make comparative studies Conditions are never exactly the same in any two places, but a great deal can be learned by studying comparable localities on different parts of the coast

The four papers that followed the introductory remarks dealt mainly with specific problems and places Dr M C Pearson, of the University of Nottingham, discussed the biology of the sea buckthorn (*Hippophae rhamnoides*) This shrub enters the succession of sand-binding plants after the marram grass stage It is found in Britain only on coastal sand dunes, and is common on certain parts of the east coast Dr Pearson's studies have been made at Gibraltar Point, a nature reserve at the north-eastern corner of the Wash It has been found that most of the plants originate from underground stems and but very few from seed This is partly explained as a result of the predation of seeds by birds and small mammals The shrub carries big spines, and so may form a deterrent to grazing animals and even to picnickers In that sense it may have value in keeping certain parts of the dunes free from erosion caused by trampling In any event it is of value in fixing the dunes, and it is used partly in that way in Holland Further research work on this interesting species is planned

Mr Cole's paper was concerned with the gathering and stabilizing of sands, silts and clays by vegetation He pointed out that only along a relatively short distance (60–70 miles) of the total length of the coast of England and Wales do dunes form the sole or partial defence, and salt marshes cover even less distance He discussed several interesting examples of the artificial accumulation of sand dunes around brushwood or other type of fencing or obstacle, and also the effect of various grasses in their relation to dune and marsh growth The remarkable growing power of marram was pointed out, but he stressed the view that its ramifying and long roots may have little effect in binding the sand The building of a new dune by British Railways at Dawlish Warren, and the planting on it of tree lupin (*Lupinus arboreus*) following the marram, was taken as a good example of the artificial production and maintenance of sand dunes

In the development of marshes the planting of *Spartina* was mentioned This grass has spread rapidly on the south coast and is now invading, sometimes all too successfully, the east coast Dr D Ranwell, of the Nature Conservancy, has recently been engaged upon methods for its eradication It will be noted that *Spartina* in this paragraph is not followed by any specific name Dr C E Hubbard, of Kew, has shown that the grass which has grown so extensively in Southampton Water and is regularly used for planting and reclamation elsewhere is not *S townsendii* but rather a chance offspring of that plant, and that so far it has not been given a specific name

Mr Cole very rightly made the point that it is wrong to rely too much on one or two species If for some reason disease developed in marram or *Spartina* grave difficulties might arise There should be experimentation with vegetation and, in certain carefully controlled circumstances, we should introduce foreign species The idea of a 'coastal garden' in which such experiments could be made has already been adumbrated

Mr C Kidson was also concerned with this same point He has studied certain parts of the coast in great detail, and as physiographer of the Nature Conservancy he has been able to make comparisons with many other parts His studies on the Somerset coast have shown the value of *Spartina* in accumulating sand and silt, and it is estimated that in part of Bridgwater Bay the level of the foreshore has been raised 5–7 feet since 1928 But here again all is not as it should be *Spartina* may act locally almost like a groyne, and it is able to hold up the longshore transport of shingle In one place 60 feet of spartinetum was overridden by shingle in one year The shingle beach behind, cut off from its supply, was combed down in big storms and became lower and so less of a protection to the land behind Mr Kidson also directed attention to the interesting work that is now being carried out along the west coast of Denmark There the foreshore has been built up by *Salicornia* spp and *Puccinellia maritima* Their spread has been much aided by the building of low brushwood dams and shallow drainage channels He also directed attention to the possibility of *Suaeda fructicosa* holding mobile shingle It is a habit of this shrub to grow at the head of marshes and at the foot of shingle ridges Prof Oliver, in his studies of Blakeney Point, directed attention to it many years ago It is doubtful if the plant can be a real deterrent to shingle movement

The remaining paper, although given earlier in the sequence, dealt with the coast of part of Lancashire

Mr Gresswell, of the University of Liverpool, has made several extensive studies of this It is put last here because it was rather less concerned with vegetation than were the others Nevertheless, South Lancashire is faced with a dune coast, and one made use of perhaps more than any other dune area in these islands The speaker discussed the erosion at Formby and the accretion at Southport This coast illustrates extremely well how difficult it is to estimate what will happen in the future Formby and district have been suffering loss for some 50 years , before then the same area was gaining at about the rate it is now losing Inland of Southport and Formby is a belt of rich agricultural land below the level of high tides, and only protected by the dune belt The dunes have long been controlled, and extensive pine forests cover part of them But these will not stop erosion Extensive sea walls may do so, and in a limited way so also may bulk accumulation—the artificial gathering of sand by brushwood groynes and careful planting This will increase the amount to be eroded by the waves , it cannot stop the erosion It may also be possible to raise the height of the beach by building groynes and stopping the sand which moves both to north and to south away from Formby But then how will this affect Southport ? The lesson has been learnt a little farther north · the protection of Blackpool has starved the beaches at Fleetwood and caused severe damage there

Change is constant along the coast , it is most noticeable in those parts faced by soft cliffs or by low-lying ground fringed by dunes and marshes It is much slower, and perhaps not measurable in a life-time, on a coast faced by cliffs of resistant rock Coastal studies are not only of significance to all dwellers along the sea and owners of land adjacent to it, but they are also of particular interest to workers in many branches of science, archæology and history. Coastal defence, in the long run, must benefit by the more leisurely rate at which certain experimental work has to be undertaken Botanists, physiographers and others, of several of our universities, are now much concerned with coastal research, and their findings are appearing with some regularity. The more we know of any particular stretch, the more certain will be the effect of any future defence work that may be necessary The four papers presented at the meeting of the British Association at York may be regarded as samples of the interest which coastal research is now provoking

J A STEERS

OBSERVATIONS OF THE RUSSIAN MOON ROCKET *LUNIK II*

THE 250-ft radio telescope at Jodrell Bank was used to receive the transmissions from the second Moon rocket launched by the U S S R Observations were made on the evenings of 1959 September 12 and 13 on frequencies of approximately 183 6 Mc /s and 19 992 Mc /s The only other part of the radio spectrum searched was in the region 19 99–20 01 Mc /s , but no signals from the probe were found

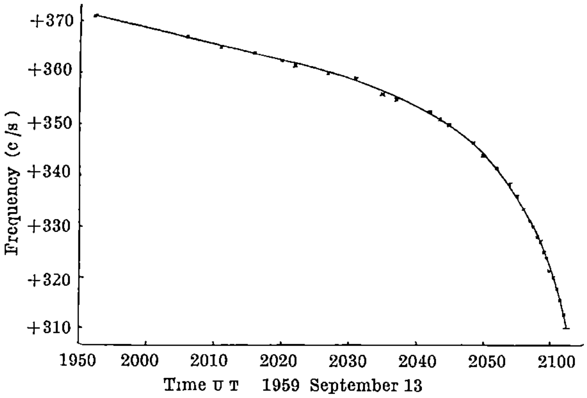

Fig 1 The variation of received frequency in cycles per second deviation from 19 992 Mc /s plotted for the last hour of the flight of *Lunik II*

The primary feeds consisted of a folded-wire dipole without reflector for the 20 Mc /s band and a folded dipole with reflector for 183 6 Mc /s The 183 6 Mc /s signal was received on a communication receiver with a band-width of 5 kc /s , and the 19 992 Mc /s on a receiver with variable band-width, 750 c /s being employed for most of the time Both frequencies carried the familiar bleep bleep' modulation pattern, and although clearly audible, the signals were not strong enough to permit reliable estimates of signal strength The signals on both frequencies ended abruptly and simultaneously at 21h 02m 23s U T on September 13

Within the limits of the 2° beam of the radio telescope at 183 Mc /s , and the rather heavy fading of the weak signals, there was no significant deviation of the position of the rocket from the predictions received from Moscow

The precise frequency of the 19 992 Mc /s signal was measured by comparison with a frequency standard to an accuracy of ±½ c /s On the evening of September 12 the measured frequency varied uniformly at 4 c /s per hour between 20h 30m and 22h 30m U T The rate expected from the effect of the Earth's rotation alone is about 6 c /s per hour, thus the rocket was at that time being slightly retarded by the Earth's gravitational attraction The variation in frequency over the final hour of the rocket's journey on September 13 is plotted in Fig 1 The smooth nature of this curve indicates that no guiding rockets were used during this period The slope of this curve is a direct measure of the line of sight acceleration and hence, using the Moon's mass, gives a maximum distance from the Moon for each point on the curve The acceleration at the end of the curve is that expected for an object moving directly towards the centre of the Moon at a height of 70 km ±150 km from the Moon's surface, and can therefore be taken as positive confirmation that the rocket did indeed hit the Moon somewhere within 7 minutes of arc from the centre of the lunar disk The velocity of impact derived from these data is approximately 3 km /sec ±0 5 km /sec

We are indebted to our Russian colleagues for computing the tracking data for the radio telescope

J G DAVIES
A C B LOVELL

Jodrell Bank Experimental Station,
University of Manchester

ON September 13, attempts were made to observe the impact of the Russian vehicle upon the Moon The telescope used was the 12 5-in reflector with which extensive lunar observation has been carried out since 1949

The impact area had been indicated as that of the Maria Serenitatis, Tranquillitatis and Vaporum Such an area would be impossible to cover adequately Since it seemed reasonable to assume that the Russians intended to land the vehicle as close as possible to the apparent centre of the lunar disk, it was considered best to use a reasonably high power (×300 to 400) and concentrate solely upon the Mare Vaporum region

Predicted impact time was 21h 01m U T Nothing was recorded at this time, but at 21h 02m 23s U T (±2 sec) a minute pinpoint of light was recorded , it appeared suddenly, and faded out within half a second The lunar co-ordinates are estimated as +085 +195 This places the position as in the Hyginus area, close to Schneckenberg

Though seeing conditions were good, the phenomenon was so uncertain and so close to the limit of visibility that it seemed unwise to trust it A report was at once sent to the Director of the Lunar Section of the British Astronomical Association, at Manchester, to await confirmation Since it now seems that both time and position are in good agreement with other observations, there is a possibility that the phenomenon did in fact represent the impact

PATRICK MOORE

Glencathara, Worsted Lane,
East Grinstead, Sussex

ON September 13, observations were made with the hope of observing the landing of the Russian *Lunik* on the Moon, using a reflecting telescope of 15¼-in aperture with a power of 300 The sky was very clear and surface details on the Moon clearly defined The Russians had said it was aimed at the Mare Tranquillitatis, Serenitatis and Vaporum, that is, the region to the north-west of the geometrical centre Last Sunday the Moon had sufficient libration to bring this region nearer to the centre as seen from the Earth than usual

This area of hundreds of square miles was 'swept' regularly The stated time for impact arrived and nothing was seen I decided to continue for a short while and 1½ min after the stated time, at 21h 02m 23s U T , I was looking at the Mare Vaporum, the nearest part to the centre At this point, north of the Hyginus Cleft and close to Schneckenberg, I observed a pinpoint of light and a kind of dark ring just as though dust had been disturbed and heated This lasted a few seconds

I understand that this observation is in accordance with the work of other observers

Bexleyheath, Kent

NEWS and VIEWS

Engineering in the University of Birmingham :

Prof G F Mucklow

PROF G F MUCKLOW retired this summer from the Chance chair of mechanical engineering, University of Birmingham He is succeeded by Dr S A Tobias, assistant director of research in the Department of Engineering, University of Cambridge Prof Mucklow has held the chair since 1940 He was educated at Rugby, McGill University and the University of Manchester He was for a short time a research associate of British Motor and Allied Manufacturers before taking up the post in 1923 as lecturer in engineering at the University of Manchester He is well known for his work on compression-ignition engines super-charging, exhaust pipe effects, wave-action in gases and related topics During his tenure of the Chance chair, the Department of Mechanical Engineering has been greatly expanded Prof Mucklow has played a prominent part in the development of postgraduate courses of instruction for men returning from industry The first course to be established was that in production engineering, and this was followed in 1950 by a most successful course in thermodynamics He has seen the Department rehoused in excellent buildings which were officially opened in 1954

Prof S. A Tobias

DR S A TOBIAS, who succeeds Prof Mucklow, was born in Vienna in 1930 He received his education at the University for Technological and Economic Sciences, Budapest, Hungary, and graduated in 1943 For four years after that he worked in industry as a design engineer of machine tools Tobias came to Britain in 1947 as a British Council Scholar, becoming a research student in the Department of Engineering, University of Edinburgh, where he received his Ph D in 1950 During 1951–54 he was an Imperial Chemical Industries research fellow at Edinburgh, working on problems of linear and non-linear vibrations, and received his D Sc Edinburgh in 1955 In that year he was appointed assistant director of research in the Department of Engineering, University of Cambridge, where he has built up a flourishing research school in the field of non-linear vibrations and in problems arising in metal-cutting processes

Agricultural Botany at Bangor

Prof Alun Roberts

PROF R ALUN ROBERTS is retiring from the chair of agricultural botany at the University College of North Wales, Bangor At Bangor the Departments of Agriculture, Agricultural Botany and Agricultural Chemistry are separate and independent, and, unlike most of the other universities where agriculture is taught, there are no subordinate professorships in those subjects Prof Alun Roberts was appointed professor at Bangor in 1945, where he had been independent lecturer in agricultural botany during 1921–40, when he was seconded as executive officer to the Caernarvonshire War Agricultural Executive Committee. His secondment was later transferred to the Welsh Department of the Ministry of Education, in order to study its problems in rural Wales. Plant ecology, especially of the grasslands of Snowdonia, has been the favourite subject of research of Prof Alun Roberts and his colleagues. His knowledge of early settlements and of Welsh history, enriched by long and close study of old estate manuscripts, enabled him to link up ecological changes with past land use. Particulars of early settlements, and later stocking of lowland and upland, with summer migration of the inhabitants from Hendre to Hafod, have added interest to his ecological studies. In addition to his scientific, historical and literary activities, he has found the time to serve on such bodies as the Royal Commission on Common Lands, the Welsh Land Sub-Commission and Nature Conservancy. His knowledge of land use, past and present, makes him a specially valuable member.

Prof J L. Harper

DR J L HARPER has been appointed to succeed Prof Alun Roberts. He gained honours in the final honours school of botany in 1946 at Magdalen College, Oxford, and was awarded the senior Mackinnon scholarship and a Department of Scientific and Industrial Research postgraduate scholarship. In 1949 he carried out research at the Imperial College of Tropical Agriculture and Colonial Microbiological Research Institute, Trinidad. He gained his D Phil in 1950 for his work in the interactions of soil micro-organisms. Dr Harper is a lecturer in agriculture at University College, Oxford, and has been a member of the Board of the Faculty of Agriculture and Forestry since 1957. While he has published much in the realms of plant pathology and of genetics, he is perhaps best known for his researches in experimental ecology. By inclination and practice he is an ecologist in the widest sense, and from an agricultural point of view, in matters of weeds, prefers to start with the biology of control rather than with chemical applications. Dr Harper, who gained a Rockefeller Foundation award, is at present working in the Department of Dr G Ledyard Stebbins, Davis University, California ; he will not take up his appointment at Bangor until next year.

Ministry of Agriculture, Fisheries and Food : Dr H R Barnell

THE Ministry of Agriculture, Fisheries and Food has announced the appointment of Dr H R Barnell as chief scientific adviser (food) in succession to Dr N C Wright (see *Nature*, 182, 631 ; 1958), who has been appointed to the office of deputy director-general of the Food and Agriculture Organization of the United Nations.

Dr Barnell was educated at Luton Grammar School and at Downing College, Cambridge. In 1929 he obtained first-class honours in the Natural Sciences Tripos Pt II (Botany) and was awarded the Frank Smart Prize. He was afterwards Frank Smart Student in botany. He was a research student in the Cambridge Department of Botany from 1929 to 1932. After a period as research assistant and lecturer in the Cambridge School of Agriculture he was appointed to the staff of the Low-Temperature Research Station of the Imperial College of Tropical Agriculture, Trinidad. His work in Cambridge was on the biochemistry of cereals, and in Trinidad primarily on the biochemistry of the banana in relation to the refrigerated and gas storage of tropical fruits. In 1943 he returned to the United Kingdom as a member of the Dehydration Division of the Ministry of Food, and was eventually transferred to the Scientific Adviser's Division, where he was primarily concerned with developments within fields of food science and technology. In this connexion he not only played a major part in developing the food aspects of Commonwealth defence science, but also was largely responsible for initiating and planning the programme of work of the Ministry's Experimental Factory and Research Establishment at Aberdeen. In 1950 he was appointed deputy chief scientific adviser.

In the course of his official work Dr Barnell has made wide and warm personal contacts throughout the food industry, not only in Britain but also overseas, where he has travelled extensively in North America, Central and South Africa, Australia and India. He has served on the governing bodies of a number of food industry's research associations, and was one of the Ministry's assessors on the Food Investigation Board of the Department of Scientific and Industrial Research. He is a member of council of the Institute of Biology. Dr Barnell's outstanding contributions in the building up of the Scientific Adviser's Division make his choice as chief scientific adviser a particularly appropriate one.

Difficulties in the Present Systems of Superannuation

A QUESTION was raised in the House of Commons on July 2 regarding difficulties in the exchange of teachers between universities and colleges of technology arising out of their differing schemes of superannuation. In reply Sir Edward Boyle, Parliamentary Secretary to the Ministry of Education, said that the possibility of transfer between the two superannuation systems had been exhaustively considered and found to be impracticable. There were, however, arrangements for integrating service under the two schemes and he believed these were not as widely understood as they might be. Sir Edward Boyle said he was investigating the matter. Transfer had proved impracticable because the pensions under the university scheme were based on an insurance policy and differed in content and kind from those under public service superannuation schemes. Mr Allen pointed out that to fill vacancies in the colleges of advanced technology and the regional technical colleges it will be necessary to go to the universities for the senior posts. However, at present the difference between the two schemes was causing many suitable university candidates to decline posts as principals and heads of departments in colleges of technology.

The Zero Gradient Synchrotron

IN a press report dated June 27, 1959, the U S Atomic Energy Commission gives details of a large orbital accelerator for protons, to be constructed at the Argonne National Laboratory, Lemont, Illinois. Economic factors always entail a compromise between high energy and high intensity in proton synchrotrons, but improvements in design may materially enhance the output obtainable at a given cost. The technical advance known as alternating-gradient focusing led to the design of the 25 GeV proton accelerators at Cern, Geneva, and at Brookhaven, but these machines may prove to be limited in beam intensity to about 10^{11} particles per acceleration pulse. In the Argonne Laboratory machine, gradient focusing is not used and the uniform guiding magnetic field is forced beyond the saturation value over a vacuum system of relatively large aperture. Beam stability is obtained by wedge-focusing effects at the boundaries of the sectors into which the 200-ft. diameter magnet ring is divided. As a result of the fairly large aperture and high injection energy (50 MeV.), pulses of about 10^{12} protons of an energy of 12.5 GeV. are expected. Much of this beam should be available outside the machine.

The Argonne Zero Gradient Synchrotron and its associated equipment will cost 29 million dollars. It will provide a strong source of all known particles and anti-particles and, since it will be especially suited to the study of rare events, it may lead to the discovery of new phenomena. The cost of such research now far exceeds the resources of individual institutions, and the development of great national or international laboratories, in which many university teams conduct research with one accelerator, is a natural consequence. The new undertaking at Argonne, which it is hoped to complete during 1962–63, has many similarities to that at Harwell, where a 7 GeV. proton synchrotron is under construction for the National Institute for Research in Nuclear Science.

Higher Education in the U.S.S.R.

A BIBLIOGRAPHICAL survey of technical and vocational education in the U.S.S.R. by M. I. Movšovič, issued as No. 30 of educational studies and documents by the United Nations Educational Scientific and Cultural Organization (Technical and Vocational Education in the U.S.S.R.: a Bibliographical Survey. By M. I. Movšovič. Pp. 53. Paris: Unesco; London: H.M. Stationery Office, 1959. 5*s.* net), covers vocational education at the elementary, secondary and higher levels. Besides books and articles, bibliographies and periodicals are dealt with in a separate section. Generally, publications are presented chronologically within each section and the articles are fairly fully annotated or summarized.

Planning in Pakistan

A BROADSHEET, "Planning in Pakistan" (*Planning*, Vol. 25, No. 433, April 20, 1959. Pp. 85–112. London: Political and Economic Planning, 1959. 2*s.* 6*d.*), which emphasizes the stimulus to central economic planning derived in the new countries of Asia from independence and the prospect of foreign aid, gives a clear but concise account of the progress of planning in Pakistan. After reviewing the effects of partition and planning in the early years, the broadsheet outlines the Five Year Plan, published in May 1956 by the Pakistan Planning Board established in July 1953, and then describes the performance and prospects of the plan. Political and Economic Planning concludes that although Pakistan is passing through a difficult phase in its economic, as in its political, development, it is tackling its difficulties with vigour. Performance, however, in some spheres remarkably good, has been uneven, and, regarded as a whole, inadequate. Big mistakes have been made, particularly because of over-ambitious schemes, and too optimistic assumptions about foreign exchange and sterling earnings, and import savings. Brilliant results in industrial development do not balance the failure to develop agriculture. Nevertheless, Pakistan's economy is basically sound. It is learning from past errors and preserving its zeal to plan and work for prosperity.

International Council of Museums

THE fifth General Conference of the International Council of Museums was held in Stockholm during July 1–8 under the presidency of Dr. Georges Salles (France). The Conference was preceded by meetings of certain committees and commissions held at Oslo and Copenhagen. Dr. Torsten Althin was chairman of the Swedish National Committee which carried out all the complicated organization for the meeting. About 350 delegates attended. The theme of the Conference and the lectures was "Museums as Mirrors—their Potentialities and Limitations". An important session dealt with the inauguration of the International Centre for the study of the preservation and restoration of cultural property. This Centre, established in Rome by the General Conference of Unesco, is designed to strengthen relations between all who are interested in the preservation of their cultural traditions. Dr. H. J. Plenderleith, recently of the British Museum, has been appointed the first director, and at Stockholm he outlined the policy of this new Centre. It aims to collect documentation on the efforts already made in this field, co-ordinate research in order to avoid overlapping, and give advice to all those requesting it. The Centre will also assist and facilitate the training of experts and is destined to become the institution best informed about the results already achieved and the research in progress. The foremost requirement at present is that the great countries should support this venture and ensure its existence after the period guaranteed by Unesco. It was agreed that the next triennial conference should take place in Holland in 1962 under the presidency of Sir Philip Hendy (National Gallery, London).

Geophysical Journal

THE appearance of the first number of the second volume of the *Geophysical Journal*, published by the Royal Astronomical Society, is a suitable opportunity to stress the contribution which this journal is making to the growth of pure geophysical research, especially in Great Britain. The fundamental importance of the papers, the careful refereeing and the speedy publication are heartening. Half this particular number contains original material. The other half consists mainly of a review of palæomagnetism and two shorter reports, one on a geophysical meeting and one on current geophysical research in Canada.

The Australian Journal of Statistics

THE Statistical Society of New South Wales is publishing a new journal, namely, *The Australian Journal of Statistics*. It is to be issued three times a year, and will contain material relating to statistical theory and methods and their application to all branches of learning. The *Journal* will give Australian statisticians an opportunity to present their work to the public without undue delay. The editor is H. O. Lancaster. The first number runs to thirty-four pages, and besides introductory material and a "News and Notes" page, contains three papers. The price of this number is 10*s.*, which is perhaps a little high for such a slim volume, but even so the Society has had to have outside financial support from some dozen organizations. The *Journal* will no doubt satisfy a need among Australian statisticians, who are making valuable contributions to the development of statistics, and every success is to be wished to the Society in its new venture.

Soviet Rubber Technology

The appearance of a regular translation of the monthly Soviet journal *Kauchuk i Rezina* under the title *Soviet Rubber Technology* (No 1, June 1959 English translation of *Kauchuk i Rezina*, Vol 18, January 1959 Pp 64 Annual subscription rates Ordinary, U K £10 10*s* Abroad 50 U S dollars, or equivalent R A B R M Members and U K non-profit-making institutions £5 5*s* Obtainable from Maclaren and Sons, Ltd , 131 Great Suffolk Street, London, S E 1) is a welcome addition to the scientific literature of the U S S R available in the English language The translation, which is being carried out by the Research Association of British Rubber Manufacturers under the auspices of the Department of Scientific and Industrial Research Translations Unit, combines technical competence and accuracy with a pleasant and readable style It is stated that the journal "deals with the efficient use of raw material, the automation of manufacturing processes in the rubber industry and improvements to the design of tyres and industrial rubber goods Articles describing the most important chemical research of interest to the rubber industry are also included" The first issue includes, in addition to original research contributions, more general articles reviewing industrial organization in the U S S R , and news items The scientific papers are about equally divided between chemistry (polymerization processes, compounding, vulcanization, etc) and physics (properties of rubber compounds, fatigue and adhesion of tyre cord, etc) The journal gives a good general insight into the technical and industrial problems of the Soviet rubber industry

The Wellcome Trust

The second report of the Wellcome Trust covers the period September 1, 1956–August 31, 1958 (Pp 72+3 plates London The Wellcome Trust, 1959), in which £1,059,919 was allocated by the Trustees, compared with £1,170,164 in the twenty years 1937–56 covered by the first report The fourth and final report on the findings of the Wellcome Marston Archæological Research Expedition to the Near East, published in June 1958, deals further with excavations undertaken by the late Mr J L Starkey and others at a mound known as Tell el-Duwier, about half-way between Jerusalem and Gaza Total expenditure by the Trustees on the Lachish expedition, including costs of publication, has amounted to £35,496 During the period 1956–58 grants made in aid of research in human and animal medicine and the contributory sciences have totalled £925,357 In making these grants the Trustees have followed their previous policy of supporting enterprises the merits of which were endorsed by the best available scientific opinion, but which had not hitherto received the help they needed Priority was given to tropical medicine, pharmacology, pharmacy, therapeutics, veterinary medicine and the history of medicine The report contains a full list of research grants and of travel grants during the period Travel grants were made to 167 research workers, expenditure increasing from £11,410 in 1955–56 to £20,022 in 1957–58 and in addition five block grants were made to the organizing committees of international congresses or of smaller specialist symposia abroad, bringing the total expenditure to £42,175 on 257 persons in the period The Trustees have also instituted a system with the Carlsberg Foundation of 'Carlsberg-Wellcome Travelling Research Fellowships' to encourage friendly co-operation on an exchange basis between Danish and British research workers in sciences bearing on human and animal medicine and two fellowships were awarded in each of the academic years 1957–58 and 1958–59 Capital grants for building projects during the period amounted to £543,500, with a further £115,160 to assist medical research libraries and museums, which included some building projects, and a further £171,065 allocated for expenditure on major items of research equipment In support or endowment of senior research posts the Trustees allocated £72,983, and towards various grants for research expenses and assistance, £25,107 New grants totalling £3,932 were made for work in the history of medicine and £957 to assist other scientific publications A grant was made to the Royal College of Physicians to cover the expected cost of producing a new edition of the 1928 Harvey film, by the use of colour photography, synchronized sound-track, animated diagrams and other appropriate improvements of cinematographic technique

English Rural Life

The Report of the Museum of English Rural Life for 1958 (University of Reading Museum of English Rural Life—Report 1958 Pp 24 Reading The University, 1959 1*s*) is far from formal, for it includes, in fact is mainly devoted to, a summary of the principles of display in a museum This part is contributed by Miss Margaret Fuller and Mr C A Jewell and is of interest and value to all museum curators especially those who deal with the difficult problem of exhibiting folk-life material In this report the policy of the Museum in relation to other regional museums is more clearly defined than it has been in the past and it is noted that it states its major task to be the formation of a national archive of information on all aspects of country life It is hoped that in the future a considerable proportion of the objects in the Museum will be available to supplement other collections or to form the nucleus of new folk sections.

Genetical Effects of Population Subdivision

P A P Moran has advanced a theory relating to some genetical effects of population subdivision (*Australian J Biol Sci* , 12, 2, 109 (1959)) The genetical effects of the subdivision of a population into partially isolated subgroups are considered in two particular cases In the first a probability model is studied in which the subpopulations are of finite size with migration between them In the absence of selection, the asymptotic rate of progress to homozygosity is shown to be very little affected by the subdivision In the second case a deterministic model is studied in which there are two subpopulations in which selective forces are equal and opposite. A stable dimorphism is then shown to exist if there is any small amount of intermigration

Fine Structure in Cells

G Setterfield, H Stern and F B Johnston have given an account of the fine structure in cells of pea and wheat embryos, based on observations using phase-contrast and electron microscopes (*Canadian Journal of Botany*, 37, 65 (1959)) The aim was to provide a basis for relating biochemical data on isolated cell fractions with the cytological structure *in situ* Pertinent observations include the following

The nuclei of all cells were similar, showing nuclear membranes, chromosomes, and prominent nucleoli. The cytoplasm contained highly developed structure which presumably reflected the incipient growth condition of the cells. Several cytoplasmic components were common to both embryos: small dense granules, endoplasmic reticulum, mitochondria, proplastids, amyloplasts, irregular bodies, plasma membranes, and plasmodesmata. The small dense granules, presumably ribonucleoprotein particles, occurred profusely, both free and in association with extensively developed endoplasmic reticulum. These particles are probably responsible for the microsomal fractions obtainable from embryos and seedlings. The mitochondria were usually relatively small (0·25–0·5μ diameter) although groups of very long (5μ) ones were occasionally found. Bodies resembling mitochondria in size and shape, but lacking cristae, were present and represent either immature mitochondria or proplastids. Reserve material occurred as starch in structurally complex amyloplasts and possibly as protein in the irregular bodies. In addition to these structures cells of the wheat embryos remote from the meristems contained prominent cytoplasmic bodies classified as 'dense' and 'thick-walled'. The dense bodies probably represent stored lipids while the significance of the thick-walled bodies, which showed a variety of forms, is unknown.

Rafflesia in Sumatra

AMONG the genera of plants which might well be described as wonderful, if not odd, *Rafflesia* must surely be accorded a leading place. Some thirteen species were recorded by Koorders in 1918 for the whole of the Malaysian region; but it now appears that some of this investigator's views may require revision. W. Meijer (*Ann. Bogoriensis*, 3, 1, 33 (1958)) has now added further information on *Rafflesia arnoldi* as observed by himself and colleagues in West Sumatra. From an examination of the literature and the material preserved in the Herbarium Bogoriense, as well as from his own observations, he has concluded that the *Rafflesia* species in question is identical with the original *R. arnoldi* of Robert Brown (1822) and that it occurs in both Central and South Sumatra. Its taxonomic position is discussed, and the author points out that *R. tuan-mudae* Becc. from Borneo is very closely related to, and may even be conspecific with, *R. arnoldi* R. Br., and that the key given in Koorders's monograph is incorrect as to the distinction between these two plants. Some information concerning other *Rafflesia* species occurring on Sumatra is also given. Observations on the growth-rate, mortality of the buds, and the possible mode of distribution of the seeds are recorded. It is now estimated that the entire cycle from seed to seed takes approximately 4½–5 yr.

Soil Basidiomycetes

J. H. WARCUP has contributed the results of an investigation on the isolation of basidiomycetes from the soil (*Trans. Brit. Myc. Soc.*, 42, 1, 45 (1959)). Whereas extensive series of dilution and soil plates from wheat-field and pasture soils failed to reveal these fungi, they were isolated from roots, and from hyphae, rhizomorphs, and sclerotia picked out from soil. Over a three-year period, no basidiomycete fructifications were found in the wheat-field although isolations from soil and roots showed that the field had an abundant and varied population of basidiomycetes. While fructifications were obtained from the pasture, the species thus seen fruiting were different from those isolated from soil and roots, indicating that the population was more varied than the fructifications alone would suggest. Some of the basidiomycetes were induced to form fructifications in culture.

Histological Localization of Peroxidase

D. S. VAN FLEET (*Canadian J. Bot.*, 37, 3, 449 (1959)) has observed that peroxidase is detectable in all tissues but is most reactive in the basophilic cells of the histogens. Oxidation of applied phenols and aminophenols by peroxidase produces quinones and quinonediimines that are adsorbed by nucleic acids and other basophilic substances in the formative centres of primordia. Localized reactions for peroxidase occur in the axils of leaf primordia prior to bud formation and on the surface of apical meristems in a spiral pattern marking the points for the future development of leaf primordia. Peroxidase is detectable in advance of or accompanying cell division and declines after the division phase; decline of peroxidase at the end of the division phase is related to the increase of phenols, naphthols and phenolases. Peroxidase declines in all tissues with the exception of the phloem; a continuous peroxidase system in the phloem connects primordia with adult tissue. The hypothesis is offered that the cellular units of the phloem peroxidase constitute a continuous system between primordia and adult tissue and are functional in catalysing the reduction of hydrogen acceptors essential to cell division and the initiation of primordia.

Oxidation of Krebs Cycle Acids by Apple Tissue

M. D. Hatch, J. A. Pearson, A. Millerd and R. N. Robertson, in a study of the oxidation of Krebs cycle acids by tissue slices and cytoplasmic particles from apple fruit (*Australian J. Biol. Sci.*, 12, 2, 167 (1959)), point out that it has hitherto been difficult to demonstrate the Krebs cycle in either cytoplasmic particles or tissue slices obtained from apple fruit. In the present investigation, evidence was obtained for the operation of the classical Krebs cycle–cytochrome oxidase respiratory system in cut tissue and mitochondria from Granny Smith apples. The respiration of cut tissue increased when either citrate, α-ketoglutarate, succinate, malate, fumarate, or pyruvate were added. Both the endogenous and acid-stimulated respiration were inhibited by malonate, cyanide, and azide. The rapid oxidation of Krebs cycle acids by cytoplasmic particles from apple flesh was also demonstrated. These particles showed cytochrome oxidase activity and contained a succinoxidase system dependent on cytochrome *c*.

Radiation in Industry

ARTHUR D. LITTLE, INC., undertook during 1958 a study of the anticipated need for high-level radiation sources and their potential uses in industry, on behalf of the CEM group of companies (Emerson Radio and Phonographic Corporation, General Airline and Film Corporation, and Revere Copper and Brass, Inc.) and the General Electric Company's Hanford Atomic Products Operation. A summarized version of the firm's report was given by S. E. Eaton and M. Michaelis at the seventh annual conference of Atomic Energy in Industry (Radiation: a Tool for Industry. Pp. i+28. Cambridge, Mass.: Arthur D. Little, Inc., 1959), held by the National Industrial Conference Board, Inc., at Cleveland, Ohio, during

April 8–10, 1959 The study was restricted to a survey and analysis of the available technological data and consisted of an examination of some 2,500 articles published during the past ten years and a series of some 330 interviews with leading workers in the field The pattern of current industrial activity in the applications of penetrating high-intensity ionizing radiations , present-day radiation costs , and radiation applications to chemicals and petroleum, to polymers, to pharmaceutical products, medical supplies and food, to power sources, and to miscellaneous substances such as semiconductors, are separately discussed Much basic work has been done on relatively simple systems, but more research on basic reaction mechanisms and more and better research equipment are required There is a considerable lack of knowledge both among industrial scientists and by the general public on the subject of radiation, its benefits, and the safeguards against its possible hazards Future long-term research on the effect of radiation on systems held at very low temperatures and very high pressures , the development of new techniques in solid catalyst activation , and the study of the usefulness of low-energy radiation in the 1–1,000 eV range, are some of the recommendations in the report It is emphasized that work up to date has been largely empirical, that possible unique features of radiation applications have not yet been fully explored, and that even radiation engineering is relatively undeveloped and radiation economics uncertain

Nobelium Research

In 1957 P R Fields and others reported the production at Stockholm of an isotope of element 102 in experiments in which curium targets were bombarded with cyclotron-accelerated $^{13}C^{4+}$ ions (*Nature*, **180**, 1010 and 1012, 1957) Two other groups have since reported experiments on the production of element 102 At Berkeley, A Ghiorso *et al* bombarded curium with carbon-12 and carbon-13 ions accelerated in *Hilac*, but did not observe the 102-isotope reported by Fields *et al* They detected and identified the presence of the isotope $^{254}102$ which has a half-life of three seconds In Moscow, G N Flerov and co-workers, by bombarding plutonium-241 with $^{16}O^{6+}$ ions, observed a short-lived product emitting long-range alpha particles with an energy of 8 8 ± 0 5 MeV which they ascribe to an isotope of element 102 Because of the negative results at Berkeley, Fields and his co-workers have recently made a thorough re-examination of their experimental data, and their comments and discussion on the Berkeley and Stockholm experiments are given in a paper in the *Arkiv for Fysik*, **15**, 225 (1959) They conclude that though their earlier mass assignment made in 1957 seems now less certain, nevertheless their re-examination has not led to any new conclusions regarding the interpretation of their results It is felt that judgment on the discovery of the element 102 should be reserved until additional experimental studies, including the properties of neighbouring nuclides, have been carried out

Borden Award of the Nutrition Society of Canada

The Nutrition Society of Canada has announced that the Borden award of the Nutrition Society of Canada will be given annually in recognition of outstanding research work done by one of its members The first award will be made in June 1960 The recipient of this award, which has been presented by the Borden Company Foundation, Inc , must be under the age of forty years and must have published the meritorious work within the preceding three years It is hoped that this award will further encourage research activities by younger members of the Society

Lady Tata Memorial Trust

The Trustees of the Lady Tata Memorial Trust, on the recommendation of the (European) Scientific Advisory Committee, have made the following awards for research on leukæmia and allied diseases in the academic year beginning October 1, 1959 *Grants for Research Expenses* Dr M Bessis (France), Centre National de Transfusion Sanguine, Paris , Dr B M Braganca (India), Indian Cancer Research Centre, Bombay , Prof G Klein (Sweden), Karolinska Institute, Stockholm , Dr J Pontén (Sweden), Pathology Institute, Uppsala , Dr M Simonsen (Denmark), Institute of Pathological Anatomy, Copenhagen , Dr A E Stuart (Scotland), Department of Pathology, University of Edinburgh , *Scholarships* Dr J Hastrup (Denmark), Institute of General Pathology, Aarhus , Dr E Kelemen (Hungary), Postgraduate School of Medicine, Budapest, Dr P A Pillai (India), Centre de Microscopie Electronique, Lausanne, Switzerland

Paul Instrument Fund Awards

Awards by the Paul Instrument Fund Committee of the Royal Society have been made as follows £1,000 to Dr H B Barlow, assistant director of research, Department of Physiology, and Mr P E K Donaldson, technical officer, Physiological Laboratory, Cambridge, for the development (*a*) of a device for automatically improving coding of messages, and (*b*) of a diffused storage sequence engine, the object being to advance knowledge of the operation of comparatively simple assemblies of nerve cells by making instruments which perform the same task as such assemblies , £600, in supplement of a previous grant, to Dr E T. Hall, senior research officer at the Research Laboratory for Archæology and the History of Art, Oxford, for improvements to an apparatus with which magnetic measurements may be made with the view of dating archæological material , £2,000 to Dr H Motz, reader in engineering science, University of Oxford (in association with Prof G B Walker, professor of electrical engineering, Essex College, Assumption University, Windsor, Ontario), for the construction of a linear accelerator working at 1 6 cm (*J*-band) , £5,500 to Prof R O Redman, professor of astrophysics in the University of Cambridge, for the construction and testing of a thin astronomical mirror of plate glass and of a new type of support system , £5,900 to Dr P M B Walker, Royal Society Research Fellow, Department of Zoology, Ashworth Laboratory, University of Edinburgh, for the construction of a new microspectrophotometer that will integrate over a defined but irregular area which can be altered quickly and easily

Grant for the Massachusetts Institute of Technology

Dr Julius A Stratton, president of the Massachusetts Institute of Technology, announced recently that the Institute had received a gift of

2,527,500 dollars (about £900,000) from Mr and Mrs C H Green of Dallas, Texas This represents the March 31 market value of 30,000 shares of stock of Texas Instruments Inc, in which form the gift was made The money will be used to construct a multi-story building on the Institute site, and will be a centre for the study of Earth sciences Laboratories for research work in geophysics, meteorology, oceanography and related fields will form an important part of the new building

University News: London

Dr P Grootenhuis, lecturer at the Imperial College of Science and Technology, has been appointed to the University readership in mechanical engineering tenable at that College The title of reader in sociology in the University of London has been conferred on Mr T B Bottomore, in respect of his post at the London School of Economics and Political Science The title of professor emeritus in the University has been conferred on Prof R J S McDowall on his retirement from the Halliburton chair of physiology at King's College, Prof Margaret M A Murray on her retirement from the chair of physiology at Bedford College, Prof J H Woodger on his retirement from the professorship of biology at the Middlesex Hospital Medical School, and Prof H J Collins, on his retirement from the Chadwick chair of civil engineering at University College

University College of Rhodesia and Nyasaland

Mr W Lloyd Jenkins has been appointed lecturer in the Department of Chemistry with responsibility for teaching agricultural chemistry Previously he was a lecturer in agricultural chemistry in the University College of Wales, Aberystwyth

The Night Sky in October

New moon occurs on Oct 2d 12h 31m U T, full moon on Oct 16d 15h 58m, and new moon on Oct 31d 22h 41m The following conjunctions with the Moon take place Oct 6d 00h, Jupiter 4° S, Oct 8d 05h, Saturn 5° S, Oct 28d 14h, Venus 0 9° N In addition to these conjunctions with the Moon, Venus is in conjunction with Regulus on Oct 1d 08h, Venus being 5 7° S, and Mercury with Spica on Oct 4d 09h, Mercury being 2 1° N There will be a total eclipse of the Sun on October 2, visible as a partial eclipse at Greenwich The path of totality begins at sunrise on the eastern seaboard of the United States, crosses the North Atlantic, Canary Islands and North Africa, ending in the western Indian Ocean at sunset The partial eclipse which will be seen at Greenwich begins at 11h 01m, reaches its greatest magnitude of 0 33 at 11h 58m and ends at 12h 56m The eclipse belongs to a series which began in 1599 Mercury is too close to the Sun for observation Venus is a morning star, rising at 2h 55m, 2h 30m and 2h 35m on October 1, 15 and 31, respectively Its stellar magnitude is approximately −4 3, greatest brilliancy is reached on October 8 Its distance increases during the month from 36 to 55 million miles and the visible portion of the apparent disk increases from 0 211 to 0 443 Mars is too close to the Sun for observation, conjunction being on October 29 Jupiter is also too close to the Sun for observation. Saturn sets at 21h 20m, 20h 25m and 19h 30m on October 1, 15 and 31, respectively Its stellar magnitude is +0 8, it remains in Sagittarius Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich Oct 10d 20h 13 4m, τ Cap m (*D*), Oct 17d 20h 04 4m, ξ Ari (*R*), Oct 20d 23h 35 1m, 318 B Tau (*R*), Oct 21d 23h 38 6m, 130 Tau (*R*), Oct 28d 4h 22 0m, 58 Leo (*R*) *D* and *R* refer to disappearance and reappearance, respectively The Giacobinids are active on October 9 and the Orionids during the third week of the month, conditions for both are unfavourable

Announcements

Lord Netherthorpe, president of the National Farmers' Union, and Prof F W Rogers Brambell, professor of zoology in the University College of North Wales, Bangor, have been appointed to fill vacancies in the membership of the Agricultural Research Council caused by the retirement of Sir Solly Zuckerman and Mr Frank Rayns

Dr A G Ogston has resigned from the chairmanship of the Editorial Board of the *Biochemical Journal* and the Committee of the Biochemical Society has appointed Dr W V Thorpe as his successor Correspondence and communications should still be sent to the Secretary to the Editorial Board, Lister Institute of Preventive Medicine, Chelsea Bridge Road, London, S W 1

The following officers of the Association of Consulting Scientists have been elected. *Chairman,* Dr J G Davis, Hon Treasurer, Dr G W Ferguson, Hon Secretary, Mr W H Stevens, 15 Hawthorne Road, Bromley, Kent

A meeting will be held on October 31 at the University of Nottingham with the object of forming a Society for Forensic Science Further information can be obtained from Mr S S Kind, 18 Hall Lane, Harrogate, Yorkshire

The eighth German Plastics Convention will take the form of an International Symposium on the Ageing of Plastics, it will be held during October 19–21 at Dusseldorf, Germany Further information can be obtained from the Arbeitsgemeinschaft Deutsche Kunststoff-Industrie, Frankfurt (Main), Karlstr 21

The German Society for Electronmicroscopy is holding a conference on various aspects of electronmicroscopy at the Departments of Pathology and Anatomy, Albert-Ludwigs-University, Freiberg im Breisgau, Germany, during October 18–21. Further information can be obtained from Tagung der Deutschen Gesellschaft fur Elektronenmikroskopie e V Pathologisches Institut der Universitat, Freiburg, Albertstr 19

The City of London College, in collaboration with the Plastics Institute, has arranged a series of eight lectures on plastics which will be given on successive Mondays at the College, commencing on October 5 Further information can be obtained from Mr A Fawthrop, head of the Department of Shipping and Commercial Products, City of London College, London E C 2

Erratum The author of the communication "Appearance of Granules in the Cytoplasm of Tumour-cell Cultures in Contact with Lysozyme" in *Nature* of July 18, p 202, is Mrs Dirce Babudieri Callerio, and not Prof Carlo Callerio as printed

FLUCTUATION PHENOMENA AND STOCHASTIC PROCESSES

THE theory of probability developed as a branch of pure mathematics Its applications to physics have now become so widespread that there is scarcely a branch to which it does not contribute significantly During the nineteenth century the establishment of the statistical nature of the second law of thermodynamics, the resolution of the irreversibility paradox, and the development of the powerful technique of statistical mechanics were all the result of applying statistical methods to an atomic population In the twentieth century the wave-particle paradox was solved by rooting atomic physics in the theory of probability At a less fundamental level, Brownian movement, diffusion and radio noise are physical phenomena the character of which is essentially stochastic , and radio-wave propagation, sea waves, nuclear reactors and polymer physics are examples of fields in which stochastic problems have recently attracted considerable attention

The apparatus of the mathematician has been accepted with gratitude by the physicist generating functions and characteristic functions for manipulating probability distributions , generalized Fourier analysis introducing autocorrelation functions, and leading to the Wiener–Khintchine theorem for fluctuation phenomena stationary in time In return the physicist has continually thrown up a variety of novel problems to challenge the ingenuity of the mathematician and maintain his interest

The two-day conference of the Physical Society on "Fluctuation Phenomena and Stochastic Processes", held at Birkbeck College on March 19 and 20, attracted research workers in many different fields Altogether, twenty-nine papers were presented , most of the participants were British, although contributions also came from the United States, Canada and Norway

In his opening remarks of welcome, Prof J D Bernal (Birkbeck College, London) pointed out that physics had learnt to deal adequately with the completely regular, and the completely random , it was the partially regular which still awaited treatment The nature of the liquid state, and biophysical problems connected with the structure of large molecules, were important examples of this

In the opening paper, Prof M S Bartlett (University of Manchester) reviewed the various types of statistical fluctuations which occurred in physics, and attempted to classify them in order of relative size In spite of the existence of occasional abnormal fluctuations, macroscopic averages in classical statistical mechanics had a 'stability' resulting from the large number of component systems involved The measurement of time and space averages for phenomena such as turbulence and random surface waves, on the other hand, made use of the ergodic properties of some stationary processes A fairly general 'weighted sum' type of process occurring in noise and Brownian motion theory was defined, together with the conditions for statistical 'stability' Finally, there was the class of possibly exponentially increasing and unstable multiplicative (branching) processes such as nuclear cascades

Dr R Furth (Birkbeck College) gave a comprehensive paper entitled "Fluctuations of Macroscopic Parameters" Macroscopic parameters ξ_i were operationally defined in finite regions Δs, of space and finite intervals Δt, of time of such magnitude that irregular fluctuations could be observed superimposed over the regular quasi-continuous functions $\xi_i(r,t)$ The theory of these fluctuations was mainly concerned with the determination of the second moments of the temporal fluctuations of the parameters ξ_i in a fixed Δs, and of the spatial fluctuations in one and the same Δt It was a characteristic feature of the theory that these moments could be expressed in terms of the macroscopic functions, $\xi_i(r,t)$, and that only some very general statistical properties of the random molecular processes responsible for the fluctuations needed to be known

In the temporal problem the correlation functions of the type $c_s(\tau) = [\overline{\xi_i(\tau)\xi_j(t+\tau)}]_s/(\overline{\xi_i\xi_j})_s$ could be calculated by making use of a generalized 'Langevin equation' , in the limiting case of $\tau = 0$ the second moments $(\overline{\xi_i\xi_j})_s$ might be obtained under conditions of statistical stationarity from statistical mechanics This latter procedure could be applied to the problem of fluctuations of strain and stress in crystalline solids

In the problem of spatial fluctuations the same method of statistical mechanics could be used for evaluating the spatial correlation products $[\overline{\xi_i(x)\xi_j(x+\zeta)}]_t$ of two parameters in two regions $(\Delta s)_1$ and $(\Delta s)_2$ in a homogeneous medium, separated by a distance ζ under conditions of 'quasi-stationarity', that is, when in spite of the finite speed of propagation of the interaction processes the values $\xi(x)$ and $\xi_j(x+\zeta)$ could be assumed to be simultaneous to a sufficient degree of approximation This method could be used to obtain formulæ for the fluctuations of electric charge and potential in a discontinuous system of conductors , and had been applied by E Morris to the problem of fluctuations of surface charge density on the surface of a single continuous conductor, and the fluctuations of potential on and outside its surface

Finally, the general problem of spatial fluctuations could be reduced to that of temporal fluctuations in such cases where the relevant Langevin equation had the character of a wave equation. This method was used by M N Moore for the solution of the problem of spatial fluctuations of strain and stress in crystalline solids

Several papers dealt with the mathematical properties of stochastic functions, and with their application to the analysis of experimental data Mr D G Brennan (Massachusetts Institute of Technology, Lincoln Laboratory) in a paper entitled "A New Approach to Certain Types of Random Functions" developed *ab initio* a theory of a class of stochastic processes which he hoped would have application to certain types of physical problem Mr M B Priestley (University of Manchester) considered the problem of detecting a signal containing several harmonic components in the presence of background noise When the noise had a uniform spectrum the appropriate quantity for picking out the harmonic terms was the periodogram But when the spectrum of the noise was non-uniform this could no longer be used, and he proposed a method of analysis based on the tail of the auto-correlation function. He also showed how a significance test could be constructed.

Mr. B. Landmark (Norwegian Defence Research Establishment) dealt with the provision of a stringent test for the Gaussian character of a given noise signal. An amplitude test was usually insufficient, and he suggested using the simultaneous variations in amplitude and phase. This had been applied experimentally to the scattering from ionospheric clouds[1], and the results were in good agreement with those to be expected for Gaussian noise.

Dr. L. Mandel (Imperial College of Science and Technology, London) gave an interesting example of a problem in which the approach of the quantum theory produced a substantial simplification. The distribution of the integral, E_T, over a time interval T of the square of random noise was quite complicated, and some of its properties had been deduced by Rice[2]. If we interpreted the noise as arising from an electromagnetic wave, E_T was proportional to the energy contained in a length cT of the wave train. Bose–Einstein statistics could be applied to the photons in this region, and the resulting probability distribution could be determined more readily.

The statistics of radioactive decay was the subject of a communication by Mr. A. C. Hughes. He was concerned with testing fluctuation theory for short-lived substances, that is, those with half-lives short compared with the time of observation. Experiments had been performed with an isotope of rhodium (half-life 44 sec.), and two isotopes of silver (half-lives 24 sec. and 2·3 min.); the agreement with theory was good.

Dr. M. N. Moore (Birkbeck College) spoke on the "Stochastic Kinetics of Nuclear Reactors". It could be shown that the square of the modulus of the reactor transfer function was proportional to the Fourier transform of the auto-correlation function for power noise in the reactor. Since the power noise represented the response to the minimum power input signal, measurements of transfer functions based upon reactor noise were of all possible measurements least subject to non-linear distortion. By performing the experiment at various power-levels and temperatures, it was possible to measure both power and temperature coefficients[3].

Some examples were given of new problems in probability which had been suggested by physical phenomena. Prof. C. Domb (King's College, London) said that if one wished to understand what was happening in a regular solution, one must study its fluctuation properties, or the distribution of clusters of different sizes and shapes as a function of temperature. Even for a purely random mixture this was very difficult, although one could readily establish a difference in behaviour in one, two or three dimensions. Thus for a 50 : 50 mixture if one considered clusters of up to 5 atoms, 88 per cent of the total number were accounted for in one dimension, 17 per cent in two dimensions and only 2 per cent in three dimensions. A critical probability entered in these problems in the same manner as those studied by Hammersley[4].

Dr. M. E. Fisher (King's College, London) discussed the shapes and sizes of polymer and polyelectrolyte molecules which seriously affected properties like viscosity. We should be greatly assisted in this field by a knowledge of the properties of non-intersecting random walks on lattices. These walks were non-Markovian and their behaviour probably differed essentially from Markovian walks. The only property which had been rigorously established[5] was that C_n, the total number of walks of n steps, was asymptotically of order μ^n. Some conjectures on the value of μ for a quadratic lattice had been rigorously disproved[6]. The subject suffered seriously from a lack of theorems of the 'central limit' kind. Dr. M. F. Sykes (King's College, London) dealt with methods for the practical determination of parameters in self-avoiding walks. Monte-Carlo methods had been used extensively by Wall and his collaborators[7], but Sykes and his colleagues had preferred to determine the properties exactly for finite values of n, rather than to attempt asymptotic extrapolation. When n was larger than about 10, irregular variations were small, and one could put forward the results with confidence. He estimated that for a quadratic lattice $c_n \sim n^{1/3}\mu^n$, where $\mu \simeq 2{\cdot}640$ (with a probable error $<\frac{1}{4}$ per cent). Also there was strong evidence that if p_n is the number of simple closed polygon walks of n steps, then ${p_n}^{1/n} \to \mu$.

Mr. J. M. Hammersley (Atomic Energy Research Establishment, Harwell) spoke on "Percolation Processes"[4]. These differed from diffusion processes in that the random mechanism was in the medium instead of the fluid. Practical examples of percolation processes were molecules penetrating a porous solid, or disease infecting a community. The processes could be studied in crystals or mazes, and the mathematics was more difficult than that of diffusion processes. It was possible to show rigorously that critical probabilities existed for crystals below which, for example, a fluid starting in one part of the medium would not spread to infinity. Upper and lower limits had been established theoretically for these probabilities, and Monte-Carlo methods had been successfully used to estimate them.

It was not surprising to find several papers devoted to the random walk problem and Brownian movement. Dr. P. H. Roberts (King's College, Newcastle) spoke on the "Random Walk on a Sphere". He was concerned with the geological problem of the path of the Pole as indicated by rocks. Other work in this field had assumed a lattice model, and a planar distribution[8a]. With the mathematical help of H. D. Ursell, he had used the correct distribution for a sphere, which, incidentally, differed appreciably from the distribution given by R. A. Fisher[8b].

The effect of persistence on a random walk was discussed by Mr. A. J. Allnut. In problems such as multiple scattering in foils the assumption that all directions of scatter were equally probable after collision was invalid; it was necessary to take into account persistence in the initial direction, and formulæ for the mean and mean square deviation could readily be derived. Mr. J. C. Barton (Northern Polytechnic, London) described an experimental method of simulating a one-dimensional random walk. This was a problem in which an analogue computer could be of value and could provide information on first passage times for a random walk with persistence[9]. (In the discussion Prof. Bartlett pointed out that theoretical formulæ for first passage times were available for all Markoff processes.)

Dr. A. R. Stokes (King's College, London) in his paper on "Light Scattering by Semi-stiff Chain Molecules" referred to a different application of an analogous problem. The distribution of the end-to-end distance of a flexible chain was Gaussian; stiffness in the chain restricted the freedom of the angle between successive links, and modified this distribution, thus influencing the light-scattering properties. The modified distribution had been calculated by Daniels[10], but he had found a simpler approach by using the Fourier transform of the end-to-end distance. The results could be expressed in a form suitable for practical calculation.

The Brownian movement of non-linear systems was discussed by Dr. D. K. C. MacDonald (National Research Council, Ottawa). Many problems in this field still awaited solution. Some results of his own approach[11] had been substantiated by R. O. Davies[12], although there was some disagreement with van Kampen[13], who maintained that the distribution of fluctuations was Gaussian even for non-linear systems. Dr. MacDonald mentioned that he had corresponded with Einstein, who agreed that the statement in his early work on the Gaussian nature of the distribution needed reconsideration.

Dr. A. Suddaby (Sir John Cass College, London) discussed the relation between the microscopic theories of transport processes developed by Kirkwood, and the macroscopic theory of Brownian movement. In the course of his development, Kirkwood introduced a friction constant β which was an integral up to time τ of the correlation of the total force on the particle at different times. The analogous constant in Brownian movement theory was determined by the correlation of the fluctuating force in the Langevin equation. These two values could be shown to agree provided $\beta\tau \ll 1$.

Dr. E. R. Wooding (University of Sheffield) presented a paper on "Recombination in a Plasma as a Stochastic Process". The rate at which ions of opposite charge diffused together was obtained by applying Kramer's method to solve Smoluchowski's equation for diffusion in a field of force. Charge transfer was assumed to occur after the ions approached to within a distance where they could enter a bounded orbit. An ion or atom in the vicinity of an orbit influenced the recombination coefficient. The resulting function was dependent on the degree of ionization, but was similar to that obtained by Thomson[14] at low pressures, and changed to Jaffe's relationship[15] at high pressures if the ionization was low.

Dr. G. Wyllie (University of Glasgow) discussed the Brownian motion of spin systems. There were two sources of interest in this problem, its neatness as a model for irreversible processes in quantum mechanics, and the experimental interest in nuclear magnetic resonance experiments. If one focused on individual spins, relaxation times were of the order of milliseconds, whereas for the whole spin system they ranged up to hours. By manipulating electromagnetic fields the spin system could be thrown into conditions far from the Boltzmann distribution. The fluctuating interaction between spins revealed itself in the shape of the magnetic resonance absorption line.

A group of papers was concerned with stochastic problems arising in radio physics. Mr. J. A. Ratcliffe (University of Cambridge) gave an introductory talk, and discussed some problems associated with the Fresnel diffraction patterns formed by an assembly of random irregular diffracting screens. It was well known that, if the correlation function $\rho_f(\xi)$ of the complex amplitude $f(x)$ over a one-dimensional diffracting screen was defined as $< f(x) f^*(x + \xi) >_{\text{screen}}$ and if $g(x)$ was the complex amplitude in the diffraction pattern over any plane parallel to the screen, then with certain reservations $\rho_f(\xi)$ was equal to $\rho_g(\xi)$. If the screen was statistically stationary over x and if the correlation function $r_f(\xi)$ was defined as $r_f(\xi) = < f(x_1) f^*(x_1 + \xi) >$ evaluated at two fixed points x_1 and $(x_1 + \xi)$, then it was also true that $r_g(\xi) = r_f(\xi) = \rho_f(\xi)$. If, however, the screen was not statistically stationary the last relation was not necessarily true.

Mr. Ratcliffe considered particularly the non-stationary case when the screen $f(x)$ could be described as an assembly of infinitely long random screens placed, in succession, in front of an aperture of finite width. He suggested that this simple example represented approximately the problems of the diffraction of (*a*) radio waves radiated from a radio star with a sharp boundary, (*b*) light waves radiated from a source of light placed behind a slit, or (*c*) radio waves reflected from an irregular meteor trail of limited length. He stated that, if the limiting aperture subtended less than the first Fresnel zone at the observing plane, then $r_g(\xi)$ was determined, not by the fine structure in the screen, but by the aperture bounding it. If, however, the aperture subtended a large number of Fresnel zones then $r_g(\xi) = r_f(\xi)$ and was determined by the fine structure in the screen.

Mr. S. A. Bowhill (Pennsylvania State University) discussed the scattering of electromagnetic waves from a continuous medium containing three-dimensional random inhomogeneities of refractive index. He had derived the form of the emerging angular power spectrum when the scales of the inhomogeneities were different in the three space directions. Contrary to previous results[16], he had found that the medium could not be analysed as a series of superposed thin phase screens, spaced in the propagation direction, and with independent phase profiles.

Mr. M. L. V. Pitteway (University of Cambridge) was concerned with reflexion from an irregular medium. Before proceeding to a three-dimensional solution for irregularities he thought one should obtain a solution for a horizontally stratified ionosphere[17] and treat the irregularities as a small perturbation. The power spectrum of the scattered wave could then be expressed as an integral in terms of the stratified solution. Dr. B. H. Briggs (University of Cambridge) dealt with the experimental problem of specifying the pattern on the ground (including time changes and movements) formed by reflexion from, or transmission through, an irregular ionosphere. He defined parameters which could be used to specify this pattern, and which could be deduced from observations at a few points on the ground[18]. As an example, he considered the application to radio star scintillations. Mr. R. P. Mercier (University of Cambridge) discussed theoretical aspects of radio-wave fading. A scalar wave with random variations of amplitude and phase across the wave front was taken as a simple model. It was assumed that the in-phase and quadrature components of the fluctuating part of the field were normally distributed, and a parameter was introduced to specify the intrinsic correlation of the fading. Various properties of this parameter could be derived, and used to interpret fading from the ionosphere.

"Coherence Properties of Partially Polarized Light" was the subject of the paper by Dr. E. Wolf (University of Manchester). Observing that the usual definition of Stokes parameters of a quasi-monochromatic plane electric wave was not unique, an experiment was analysed which led to a unique coherency matrix and to a unique set of Stokes parameters The degree of polarization of such a wave was also equal to the maximum value of the degree of coherence which existed between the components of electric vibrations in orthogonal directions in the wave front This suggested a new method of measurement of the degree of polarization, based on interference experiments

Prof E G Richardson (King's College, Newcastle) referred to experiments on the propagation of sound waves in a fluid having random variations in either density or momentum, whereby the amplitude and relative phase of the signal picked up after transmission through the medium fluctuated in time The former type occurred near the critical point of a fluid or of a mixture of liquids, the latter in the atmosphere or in the wake of an obstacle or, again, in a boundary layer Analyses of such measurements were presented In the case of the liquid mixture a correlation was sought between the pattern of the scattered radiation and the mean size of the clusters which formed at the critical point As an example of the second type, frequency spectra of the modulations of the sound signal transmitted athwart the wake of a cylinder involved the discerning of peaks in the spectrum against the background of fluctuation 'noise' in the general flow

Dr M S Longuet-Higgins (National Institute of Oceanography) discussed "Sea-Waves as a Stochastic Process" He showed a typical record of pressure at a fixed point on the sea bed which agreed closely with a Gaussian distribution Non-Gaussian features usually appeared when the waves were steep and near the point of breaking, or in shallow water. To describe the sea surface a random process two spatial dimensions and one of time were needed, the practical problem for wave forecasting was to relate this to winds and other relevant factors Dr Longuet-Higgins also listed a number of properties of a Gaussian surface which might be of use in determining the spectrum, these included wave slopes[19], 'specular points' and 'twinkles'[20]

The final paper was given by Prof E W Montroll (University of Maryland) on a stochastic treatment of traffic flow Experimental data indicated that the acceleration of a car in a line of traffic at time t was proportional to the velocity difference between itself and its neighbour at time $(t - \Delta)$, where $\Delta \sim 1\ 5$ sec and the proportionality constant[21] was 0 37 sec^{-1} Theoretical investigation showed that the motion became unstable when the product of lag time and proportionality constant exceeded 1/2 Thus the experimental data showed that driving was usually on the verge of instability 'Acceleration noise' was put forward as a parameter which would characterize the driver – car – road complex under various conditions[22] Reasonable agreement was obtained with traffic flow measurements[23]

The conference was organized at the suggestion of Dr Furth, who is to be highly commended on his initiative The one hundred participants would undoubtedly wish to express their thanks to him, to Birkbeck College, and to the Physical Society for the excellent arrangements

BIOMECHANICS

ON April 17 the Institution of Mechanical Engineers held a symposium on "Biomechanics" with the purpose of bringing medical men and engineers into closer contact

Biomechanics, in its broadest sense, may be defined as the branch of science which applies the principles of mechanics and the techniques of engineering to the human body in the process of its repair, and in the field of man – machine relationship, where man is the essential link in operating these machines

The symposium was opened by the President of the Institution and the papers and discussion were presented under the chairmanship of Prof S J Davies In the opening paper on the importance of biomechanics as a service to man, illustrated by a discussion of problems in metallic osteosynthesis, J M Zarek, from King's College, London, gave a brief account of the nature of biomechanics as a new field of endeavour in which some of the engineering knowledge may be of direct use to the medical man The man – machine relationship was only mentioned, as this aspect of biomechanics appears to be already well appreciated by the engineers and was not dealt with at the symposium in detail After discussing the scope of biomechanics, the general history and current British activities in this field were reviewed Problems of bone repair were considered at length and the work in the Civil Engineering Department at King's College, London, on the stress/bone formation relationship and the behaviour of metals in the human body were discussed

In the second paper, R I Tanner, from the University of Manchester, presented a paper on some tests on 'Fluon' as a material for artificial animal joints in which results of artificial hip-joint friction and wear are given They are based on the results obtained by means of simple pendulum apparatus which provides a reasonable approximation to the walking motion of a normal person

A critical review of published work on the nature of lubrication in animal joints was given by John Charnley from the Department of Orthopædics at Manchester Further, some of the experiments which have been accepted in support of the theory of hydrodynamic lubrication have been repeated by him to show that the lubrication of animal joints is almost certainly a boundary phenomenon Charnley emphasized that the coefficient of friction of animal joints reaches a very low figure and surpasses in slipperiness any combination of sliding surfaces known to engineering

A paper on the provision of workable substitutes for missing or defective limbs was presented by D S McKenzie and Brig N A M Swettenham, from the Limb Fitting Centre, Ministry of Health, Roehampton

Limb fitting has been essentially a craft until quite recently, and many ideas current in the last century exist materially unchanged to-day This situation is now changing as a great deal of research work on artificial limbs with emphasis on fundamental studies is in progress Some of the problems here are very complex The prosthesis has to replace a human component but it does not necessarily follow that its mechanical design should copy that of the part it replaces Amputation often changes the pattern of muscular control and weight bearing The paper also described some of the features governing the construction of artificial limbs Each case has to be treated individually and *ad hoc* modifications have to be made to suit individual needs In a research field of this nature it is difficult to prove that a proposed change has merit, and evaluation techniques still require much development Some devices evoke general acceptance, but more often individual responses vary and the type of case for which the new idea is best suited must be discovered Only users can supply the final answer, but they cannot give up unlimited time to experimentation Objective testing is therefore necessary to eliminate obvious flaws and shorten user trials

Following the presentation of the papers, a film entitled "Late Results of Four Massive Internal Prosthesis" was shown by A C Bingold and W G France Here the authors gave an excellent picture of how, through the co-operation of surgeons with engineers, instead of amputation, limbs can be saved and restored to their normal use

The success of the symposium, I think, was reflected in the very interesting discussion which followed and well exceeded the time limit allocated for this purpose

The Institution was honoured by the presence of Sir Harry Platt, of the Royal College of Surgeons, who, in opening the discussion, stressed the importance of interdisciplinary work between the medical men and engineers He said that the symposium had clearly demonstrated that some of the surgical techniques now in use are so complex that it is impossible for one profession only to solve the problems involved

Dr F C Harper, of the Building Research Station, showed a film and some results obtained in the course of studying the forces exerted by the human foot in walking, the emphasis there being on the wear resistance of floor surfacing materials

Dr J D Moreland and Mr S J Thurlow, of the Road Research Laboratory, discussed their investigations into the problems connected with road crash injuries

Mr E H J Smyth, an orthopædic surgeon from the Southampton and Isle of Wight Hospital Groups, presented in a very interesting manner his views on the functional significance of the formation of trabeculæ in the neck of the femur

Finally, because of shortage of time, after a number of speakers discussed a variety of subjects of their own interest, the authors of the papers answered various points raised in the discussion very briefly

In conclusion, the large attendance and the discussion were an indication that the Institution of Mechanical Engineers had organized a successful symposium which from the 'mixed' audience indicated the growing affinity between engineering and medicine in the process of alleviating human suffering

The Institution of Mechanical Engineers will shortly publish the proceedings of the symposium, which will include the discussion and communications

J M ZAREK

INTERNATIONAL STARCH CONVENTION, 1959

THE ninth annual Starch Convention, which took place at the Cereal Research Station, Detmold, Germany, during April 21–23, was attended by 360 chemists from seventeen nations The papers which were read to the meeting were divided into four sessions, on research and analysis, starch manufacture, starch fractions and derivatives and on industrial applications

The opening address was delivered by T J Schoch (Argo, Illinois), whose theme was the application of modern methods of starch chemistry to characterizing its useful properties Waxy sorghum starch, which is comprised wholly of amylopectin, can be given some of the characteristic properties of corn starch by cross-linking the polysaccharide chains with phosphate, epichlorhydrin or fatty acid groups The amount of cross-linking agent required to achieve this result is only 1 part per 1,000 parts of starch Thus waxy starches, which normally give rise to fluid pastes, are deprived of this property and become 'short' Simultaneously their resistance to shear increases greatly Another result is that such starches lose the property of gelatinizing in water at a precise temperature, and instead show a gradual increase in solubility with rising temperature Cross-linking also results in a marked improvement of resistance to freeze-thaw cycles, which has important implications for the food industry

Improved freeze–thaw characteristics show as a lower rate of sedimentation after freezing, and better gloss and transparency of the paste

The new properties of amylopectin obtained by cross-linking can be explained by a greatly reduced rate of retrogradation and greater internal rigidity of the starch molecule The technique of cross-linking can be extended to dextrines, which are used as remoistening gums on envelope flaps and labels The deterioration of such gums on ageing has been shown to be due to retrogradation of the dextrine in the presence of small amounts of water By using the hydroxyethyl derivative of dextrines for gumming purposes, the ageing characteristics of flap gums can be largely avoided Finally, Dr Schoch explained how starch films, which have been laid down by slow evaporation of water, have a greatly increased resistance to water when compared to quickly dried films This again can be shown to be due to retrogradation taking place during the slow drying of films

Prof M Samec (Ljubljana, Yugoslavia) described how the bursting and tear strength of paper can be markedly improved by using a starch size which has been previously irradiated with cobalt-60 This process might become of great importance if the cost of the radioactive material would be reduced in the future

The use of starch as sizing agent in the paper industry was described by J Seaman (Slough, Bucks) A beater size should preferably be a potato starch soluble in cold water, of which 5 per cent w/w is added to the paper pulp Such starches are manufactured by passing a slurry containing starch and borax over steam-heated drying rolls The product when re-dissolved has *p*H 8 5 at 5 per cent concentration For surface sizing it is advantageous to use an oxidized starch, which is manufactured by treating potato starch with sodium hypochlorite The material has to be cooked with water before use to give a size having *p*H 7 5 at 15 per cent solid-content For paper coating, white potato dextrine (1 part) is added to china clay (5–6 parts) and the mixture made up with water to a slurry having a solid content of 50 per cent

When selecting dextrines for coating purposes, it is essential to choose one with a maximum rate of set back to enable the coating to set on the surface of the paper as rapidly as possible

Prof M Mautner (Zagreb, Yugoslavia) described a new method for the continuous production of glucose by the acid hydrolysis of starch The starch slurry is first treated with hydrochloric acid and is then passed into a conical chamber, which rotates very quickly about its long axis The chamber is heated externally by steam and is provided with an inlet at the wide end and an outlet at its apex Ungelatinized starch particles are forced by centrifugal force to the walls of the chamber, where they gelatinize instantly In so doing their specific gravity is reduced and they are replaced by further ungelatinized granules The chamber has a peripheral speed of 30 m /sec and it can deal with 2½ tons of raw starch per hr After leaving the chamber the starch paste is fed into a series of flat, box-like heat exchangers, where the final conversion of starch to glucose takes place It is estimated that the total time required for conversion is only 18 min

At the Convention a total of twenty-two papers was read and they will be reprinted in full in the journal *Die Starke*

The actual Convention was followed during April 24–25 by the first meeting of the International Standards Organization Technical Committee No 93, which has been set up to establish international recommendations for analysis of starch, including its derivatives and by-products There were 65 delegates present from Czechoslovakia, Denmark, Eire, Finland, France, Germany, Hungary, Italy, India, The Netherlands, Norway, Switzerland and the United Kingdom The chair was taken by Prof K Heyns (Hamburg), the secretariat being held by the German Standards Association The British side of the work is in the hands of the British Standards Institute Committee on Analysis and Testing of Starch Products , ten members of this committee—representing manufacturers and users of starch and associated products, research interests and Government departments—were present The work already done by the British Standards Institute Committee enabled the British delegation to give a strong lead at these inaugural discussions of the International Standards Organization and many of the United Kingdom proposals were adopted

It was agreed that the scope of the new International Standards Organization committee should cover terminology, methods of sampling, methods of analysis and examination of starch, its derivatives (including hydrolysis products and dextrines) and its by-products

E Dux

THE EDUCATION OF TECHNOLOGISTS

THE presidential address to the Institution of Metallurgists, delivered by Prof A J Murphy on May 12, covered a field involving not only the metallurgist but also the technologist in general, and in no small measure the pure scientist as well

After dealing with matters of a more or less domestic nature, Prof Murphy turned his attention to the general background desirable in the training of the technologist From this the following has been extracted

Sooner or later in any discussion on the education of scientists and technologists the remark will be made "What a pity it is that you cannot give your bright young technical men some sense of cultural values" Often this can be recognized as the defensive manœuvre of a dyed-in-the-wool classicist, who, in an age of automation, atomic energy and satellites sighs for the day when he could with impunity, and publicly, dismiss science as something they used to call "stinks" at school

But there is more in it than that It must be admitted that far too many technically competent men are distressingly inept in communication by speech and writing This is very regrettable The blame rests primarily on the schools—of that I do not have the slightest doubt I do not believe that any reasonably intelligent boy who had been properly taught the elements of English grammar and syntax could perpetrate the mangled compositions which one encounters alike in Ph.D. theses and the scripts of technical representatives. As for some of the efforts at reported speech which one receives from secretaries of technical committees, one can only regret that the writers have not been able to experience the intellectual satisfaction to be gained from a proper appreciation of the sequence of tenses. The Institution of Metallurgists is trying to do something toward remedying this state of affairs by requiring the demonstration of at least a modest competence in the use of the English language as part of the qualification of a metallurgist. We must hope that by gradual seepage down the line this measure will encourage the schools to increase their efforts in teaching English for use.

We are all fully persuaded that premature and immoderate specialization can produce monsters. Once such damage has been done there is not much hope for rescue operations conducted in university faculties of science and engineering or in technical colleges. Again I think we must look to the schools for salvation. An awareness of what goes on outside his specialization ought to have been gained in the technologist's school days. Special lectures of one hour a week in the liberal arts, isolated from the technological course, make no appreciable impression on deficiencies in this respect which the student has brought with him to the university or technical college.

Somehow time must be found, or regained, in the schools for these opportunities to taste the many savours which go to make a full life. The late Prof. Samuel Alexander said that liberality was the "spirit of pursuit, not a choice of subject". Sir Eric Ashby, in a series of stimulating papers, and lately in his book "Technology and the Academics", has denied that technology and culture are antitheses, and has urged that technology properly taught can provide a path to culture through a man's specialization and not by by-passing it. In this respect technology has the advantage over pure science in its opportunities for developing cultural appreciation, since applied science necessitates contact with one's fellow-men outside one's specialization. If the technologist is to achieve the successful application of his science he must study his fellow man in order to understand his desires, his fears and his needs.

To the man whose training has been along the route of an apprenticeship and a Higher National Certificate qualification, corporate membership of a professional institution opens a door to promotion to positions of major responsibility which otherwise would remain closed. Much could be written about our neglect, during the thirty years or so before and after the beginning of the century, to appreciate the immensely valuable national asset which we possessed in this type of man, and we may yet have cause to regret our improvidence. Apprenticeship in the engineering and metallurgical industries fell into sad disrepute in those days. Less and less did it serve as a springboard for advancement to executive appointments save for men of exceptional ability, whom no system, however bad, could have held back; more and more it became merely a procedure for instilling into the youngster the minimum technical knowledge which operative employment required. In our time we see a new approach. Positive action is taken to encourage and help the young man in industry to broaden his educational horizon and to aim at the most ambitious target which his intellectual ability brings within his scope.

It is a good thing from time to time to count one's blessings. It adds zest to the enjoyment of good times and it helps to keep one's sense of proportion when things are not going so well. Sometimes a piece of good fortune is too obvious to be overlooked. There are also those blessings which become evident only after a little reflexion. In this category comes the privilege which we enjoy in a calling in the absorbing world of science and technology. It is indeed a happy circumstance for us that we make our livings by engaging in an occupation which commands our great interest, even apart from the tangible rewards which economic necessity compels us to exact. When we contemplate the lot of many of our fellow-citizens who must earn their daily bread by the performance of ineffably dull chores, then surely we cannot deny the boon with which by contrast we are favoured.

VISUAL ILLUSTRATION OF UNIVERSITY LECTURES

AT the annual general meeting of the British Universities Film Council, held at University College, Cardiff, on May 8 and 9, one session was devoted to a discussion, under the chairmanship of Prof. G. E. H. Foxon, on the problems of illustrating university lectures by film and related techniques. It was attended by several guests as well as the representatives of the universities on the Council.

Opening the discussion, the guest lecturer, Mr. C. E. Engel, of the Department of Medical Illustration, Guy's Hospital Medical School, and editor of *Medical and Biological Illustration*, took as his subject "The Lecture Theatre of the Future". He pointed out that considerable information was now available on several matters influencing design of lecture theatres, including the visibility of blackboards and of projection screens of different materials. The value of the 'recessed' type of screen was particularly stressed as it allows of sufficient illumination in the theatre for note-taking without impairing the quality of the projected image. Methods involving complicated arrangements of projection are usually considered unsuitable for university use because they upset the speed of the lecture and come between the lecturer and his audience by interposing another person as projectionist. Several devices to overcome this trouble were demonstrated, including: first, a projector for 2 in. × 2 in. slides with automatic slide change and change of focus; and secondly, the prototype of a magazine loading projector for loop films. The details of operation of this loop projector were demonstrated in close-up by closed-circuit television (with apparatus kindly lent by the Marconi Wireless and Telegraph Company), thereby showing another method of lecture illustration. Mr. Engel concluded by pointing out the need for a magazine-loading cine-projector operated by the lecturer by remote control so that the film sequence could be introduced precisely when required and, if necessary, repeated

Mr C J Duncan (University of Durham, King's College, Newcastle upon Tyne) said that the normal 'instructional film' with its elaborate production, titling and sound commentary was quite unsuited to the university lecture , what is required is a short piece of film which illustrates only the essential event in which the movement being dealt with occurs As an example, Mr Duncan demonstrated how, in describing a piece of apparatus, its components could all be shown by slides, thus enabling the speed of explanation to be varied on different occasions and the moving sequence showing the apparatus in use could be projected at the appropriate moment This method is of value in that it avoids the necessity of producing a complete film with all the necessary editing and titling, and so is much less expensive than an instructional film , also it is much more flexible and any subsequent modification of the apparatus or technique being demonstrated merely necessitates the substitution of a small piece of film and not the production of a completely new full-length film These short films lasting some 15–20 sec can be called 'moving diapositives', and if several are joined together by short lengths of blank film, during which the projector is stopped, several such short sequences can be shown in one lecture without re-threading the projector and thus disturbing the lecture

Prof H I Stonehill (Royal Military College of Science, Shrivenham) reviewed the use of television as a medium of instruction at college- and university-level in the United States, emphasizing how much this method was being employed there for instruction at all levels In discussing in more detail its use in universities an account of some assessments of its value was given , apparently, results so far indicate that students 'attending' lectures by television do as well in tests as those actually present in the lecture room Some students were reported to prefer television lectures because, when concentrating on the screen, they had less difficulty in preventing their attention from wandering than when in a large audience

Mr A M P Brookes (Cambridge) described experiments now going on in the Engineering Laboratories at Cambridge where, on account of large numbers, some students were 'attending' the lectures in an adjacent room to which the lecture was televised The lectures involved were those given by Mr Brookes himself, and he told of the first attempt and the modifications in technique that had been made in succeeding lectures Small television cameras can be set up in the lecture room without waste of space, so sited that they cover the movements of the lecturer and show the blackboards clearly It is important that the lecturer should appear in the picture in reasonable proportion when seen against the blackboard , close-ups which tend to turn the lecturer into a 'television personality' are to be avoided The necessity for keeping in view of the television cameras does tend somewhat to limit the movement of the lecturer on his rostrum It is of great importance that the camera covering any one blackboard remains in use long enough for students to copy any diagram or note which it is expected they shall copy At present, Mr Brookes and his colleagues are learning by trial and error, but inspection of students' note-books indicates that those receiving the lecture by television make as full notes as those in the lecture-room

During a general discussion which followed, Mr Brookes, with the aid of the equipment present, gave a demonstration of 'blackboard work' by television

This session covered a wide field, and while little summary is possible, attention may be directed to the point made by several speakers that films and television are so well adapted to mass instruction that their possible uses at university-level tend to be overlooked This is particularly so with films, for although instructional films have been available for many years, suitable film illustration for a university lecture is hard to come by This, as has already been suggested, is because instructional films are produced as complete entities There is a need for the provision of short lengths of film illustrating those particular points, which are found in several sciences, when movement plays such an essential part that it cannot be illustrated by other means Whether this can be done on a commercial basis or whether such sequences, perhaps produced in the course of research, can be exchanged between university departments remains to be seen

G E H FOXON

THE HALDEN (NORWAY) REACTOR

THE boiling heavy-water reactor of the Norwegian Institutt for Atomenergi at Halden, which is to be used for a joint programme of research and experiment organized by the Organization for European Economic Co-operation, European Nuclear Energy Agency, was successfully operated for the first time on June 29, 1959 The reactor, moderated and cooled with heavy water and fuelled with natural uranium, is located in an excavation in a rock near the paper and pulp factory Saugbrugsforeningen in Halden, 120 km south of Oslo It is the first boiling heavy-water reactor in the world, and the first boiling-water reactor in Europe Besides its main function as a power demonstration reactor for studying problems associated with boiling heavy-water reactor systems, the installation will also produce some 15 tons per hour of process steam in the secondary light-water circuit Eventually this steam will be used in the paper factory and it is believed that this will be the first nuclear process steam installation

The reactor was designed at the Netherlands–Norwegian Joint Establishment for Nuclear Energy Research, Kjeller, and was built by the Norwegian Institutt for Atomenergi The main sub-contractors were the Kvaerner-Myhren, -Thune Combine (mechanical installations), the Chr Michelsens Institutt (control and instrumentation), Høyer Ellefsen (civil engineering work), the U K Atomic Energy Authority (fuel), and the U S Atomic Energy Commission (heavy water) The total cost of the plant, including heavy water and the first uranium fuel load, was 3 5 million dollars

The Organization for European Economic Co-operation Agreement concerning the reactor was signed in June 1958 by Austria, Denmark, Euratom (representing Belgium, France, Germany, Italy, Luxembourg and the Netherlands), Norway, Sweden, Switzerland and the United Kingdom It provides for a joint programme, budget and staff for research and development work with the reactor for a period of three years Through agreements with the Institutt for Atomenergi, the United States and Finland are also associated with the reactor project At present, a professional staff of thirty, recruited from the participating countries, is attached to the project During the next six months the reactor will be operated at low power-levels to enable fundamental reactor physics experiments to be performed After this period the power level will be increased gradually up to the design power of 10 MW thermal energy

The reactor plant will be officially opened by H M King Olav on October 10

The Halden Reactor Project is one of several joint undertakings sponsored by the European Nuclear Energy Agency of the Organization for European Economic Co-operation , others are the 'Eurochemie' company for the chemical processing of irradiated fuels (established by an international convention signed in December 1957) and the *Dragon* high-temperature gas-cooled reactor project, work on which began last April

THE DANISH ATOMIC ENERGY COMMISSION

THE report on the activities of the Danish Atomic Energy Commission* for the period April 1, 1957, to March 31, 1958, deals mainly with the erection of the Risø Research Establishment and the three reactors *DR*1, *DR*2 and *DR*3, and the work of the six departments of the Establishment The membership of the Commission remained unchanged during the period under review, and Prof Niels Bohr continued to act as chairman The total cost of the Establishment was originally estimated at about 100 million kroner The expenditure so far, including that estimated for 1958–59, is about 90 million kroner, of which about 60 million kroner is for expenditure on buildings and the remainder for the three reactors and the requisite technical and scientific equipment On March 26, 1958, the Finance Committee authorized an additional expenditure of up to 2 5 million kroner on a linear accelerator to be used for experiments on the preservation of food and for other irradiation experiments

On August 15, 1957, the first of the three reactors began to operate, and by September the chemical, reactor engineering, electronics and physics laboratories together with the administration building were completed and in use Then followed the health physics department, the library and the canteen, and early in 1958 the agricultural department, the lecture hall and the buildings to house the *DR*2 reactor group were completed, leaving only the buildings for the *DR*3 reactor to be erected A detailed map attached to the report shows the complete layout of the Establishment

In the physics department one group has been working on the construction of a laboratory for investigations of beta- and gamma-ray activities , another group with neutron spectroscopy , and a third group with solid state physics, particularly the study of the effects of radiation damage to metals and graphite A study has also been made of the literature on deuterium fusion and of the theoretical aspects of the utilization of the energy from deuterium fusion The electronics department has undertaken active research on scintillation counters and on the development of a reactor simulator Two study groups were formed in the reactor engineering department The first was engaged in drafting a project for a heavy-water-moderated power reactor with an organic cooling medium, and the second for a high-temperature gas-cooled reactor

A section of the report is devoted to the International Atomic Energy Agency, and to regional co-operation in Europe, including the Organization for European Economic Co-operation and Euratom The report also gives details of geological surveys in Greenland , relations between the Commission and commerce and industry , educational activities which included experimental reactor courses with *DR*1 and lecture courses at the Technical University of Denmark , and general information services

---

* Report on the Activities of the Danish Atomic Energy Commission for the period from 1 April 1957 to 31 March 1958 Pp 62 (Copenhagen Danish Atomic Energy Commission, 1958)

ATOMIC POWER CONSTRUCTIONS, LTD.

ATOMIC POWER CONSTRUCTIONS, LTD , 28 Theobalds Road, London, W C 1, which was formed in December 1956, is carrying out extensive research and development in connexion with the national nuclear power effort The research programme is concentrated at the company's laboratories at Heston, Middlesex, and a booklet* recently prepared gives a survey of the problems being tackled In the Calder Hall type of reactor the uranium is arranged in a pattern of vertical rods embedded in a large cylindrical 'core' of graphite The heat generated in the rods is carried away by blowing carbon dioxide gas past them, and in order to economize in pumping power the reactor designer puts the whole of the carbon dioxide gas circuit under a pressure of some 20 atmospheres Consequently, the core and uranium must be enclosed in a pressure vessel

Most stringent precautions must be taken against failure of the pressure circuit in which the carbon dioxide circulates, and a major part of the work undertaken by Atomic Power Constructions, Ltd , is concerned with proving the materials and fabrication techniques which are used in the construction of the pressure vessel An important problem is creep of the steel to be used for the pressure vessel and for the heat exchangers, and in order to acquire the necessary information sufficiently quickly an air-conditioned creep laboratory containing a battery of seventy creep machines has been set up The strain ageing of steels at elevated temperatures , weldability and welding techniques for use with selected steels, and the chemical compatibility of the various materials used in the reactor with the carbon dioxide coolant gas, are some of the other problems being investigated by the Metallurgical Division A considerable expansion in facilities is planned during 1959, and additional long-term researches relating to uranium, magnesium and the weldability of steel will be started The design of the best heat transfer surface for the fuel elements is at present largely empirical and at the Heston Research Laboratories two experimental rigs are provided for experimental tests In both, the fuel element can is placed in a working section and the heat developed in the uranium simulated by an electric heater Facilities for basic studies in heat transfer and in other design problems have also been set up, and these facilities comprise a flow visualization rig and associated equipment in which water replaces the pressurized carbon dioxide as the working fluid

---

* Research and Development at the Heston Laboratories of Atomic Power Constructions, Limited Pp 10 (London Atomic Power Constructions, Ltd , 1959)

Crompton Parkinson, Ltd, the Fairey Aviation Co, Ltd, International Combustion (Holdings), Ltd, Richardsons Westgarth and Co, Ltd, and Nuclear Civil Constructors (Trollope and Colls, Holland and Hannen, and Cubitts) form the five member companies of Atomic Power Constructions, Ltd

COFFEE RESEARCH IN THE BELGIAN CONGO

TWO investigations of a fundamental character on the genus *Coffea* have recently been published by the Institut National pour l'Étude Agronomique du Congo Belge, (i) Recherches sur l'Autostérilité du Caféier Robusta (*Coffea canephora* Pierre) by M Devreux, G Vallaeys, P Pochet and A Gilles (No 78 1959 Pp 44+8 plates 40 francs), (ii) Recherches sur les Affinités Chromosomiques dans le Genre *Coffea* by J Bouharmont (No 77 Pp 94+2 plates 70 francs) The self-sterility of Robusta coffee has been known in a somewhat confused way for many years, but no convincing demonstration of this phenomenon has previously been presented This information is important in preparing a rational programme of selection The investigators of the work indicated above have now shown, under strictly experimental conditions, that this variety is quite self-sterile As a result of many controlled self-pollination experiments, using 19 clones and based on a very large number of flowers, for example, more than 15,000 in one instance, an extremely small number of fruits has been obtained, the highest percentage not exceeding 0 24 By contrast, when the flowers of the same clones were subjected to cross-pollination, a number of ripe fruits, 30–40 per cent, was obtained The self-sterility is not attributed to defects in floral structure or in micro- or macrosporogenesis but to anomalies in the formation and growth of the pollen-tubes In no case were these able to traverse the style While a genetical explanation in terms of incompatibility may be advanced, validation has still to be obtained

Observations on the chromosome numbers of thirteen species of *Coffea*, including all the well-known species such as *C arabica*, *C liberica*, *C stenophylla*, etc, have shown that all those examined are diploid with 22 chromosomes, except *C arabica* which has 44 Certain hybrids are diploid and others tetraploid The nuclear behaviour at mitosis is apparently identical in all the species Measurements of chromosome lengths show that these are all much alike It is considered that these comparisons by measurement confirm the close systematic relation of certain species, but it does not enable a general classification of the genus to be established An average idiogramme of the African *Coffea* has been prepared The author concludes that the genus is a very homogeneous one, and that the species investigated are closely related from the cytological point of view Lastly, this investigation has yielded no evidence of difficulties in obtaining interspecific hybrids

BOTANY IN SCOTLAND

AN agreeable and very well-deserved tribute has been paid to Prof J R Matthews, regius professor of botany in the University of Aberdeen, by his friends, past and present colleagues and former students, on the occasion of his seventieth birthday During his twenty-five years as regius professor he has greatly increased the stature of his Department, has helped the cause of botanical science by his work on the councils of various societies and has made many valuable contributions to botany, especially in the field of research relating to the origin and distribution of the British flora The presentation volume under consideration has been printed for the Botanical Society of Edinburgh and appears as a special number of the *Transactions* (38, March 1959 15*s*) There is a foreword by H R Fletcher, and, as might perhaps be expected, a number of the articles relate to the ecology of Scottish plants But there are also some contributions dealing with other aspects of botanical science, for example, "Some Fundamental Considerations on the New Morphology", by H J Lam, "Peristome Teeth and Spore Discharge in Mosses", by C T Ingold, a biographical essay on "The Rev John Walker (1731–1804)—a Notable Scottish Naturalist", by G Taylor, of the Royal Botanic Gardens, Kew, and J Grant Roger has contributed a useful article on the "Conservation of the Scottish Flora"

Further evidence of the work of this distinguished and active botanical society has also been published (*Trans*, 37, Part 4, 1959) This is devoted entirely to various aspects of Scottish botany Thus there are floristic studies of a number of different regions, sometimes combined with geological observations D Ratcliffe has contributed an article on the "Habitat of *Koenigia islandica*", and D G Downie on "*Rhizoctonia solani* and Orchid Seed" There is a special cryptogamic section by D M Henderson and an alpine section by D Grant Roger There is also a useful general article dealing with botanical research in Scotland This gives a brief account of the activities of the main research institutes, including those devoted to marine biology and nature conservancy, but it is not concerned with university departments of botany

HABIT OF ICE CRYSTALS GROWN IN HYDROGEN, CARBON DIOXIDE AND AIR AT REDUCED PRESSURE

By A. P. van den HEUVEL and Dr. B. J. MASON
Imperial College of Science and Technology, London

ICE crystals grown from the vapour in air at normal atmospheric pressure show a remarkable variation of crystal habit with temperature. This has been closely investigated by Hallett and Mason[1] by growing crystals on a thin fibre running vertically through the centre of a diffusion cloud chamber in which the vertical gradients of temperature and supersaturation were accurately controlled and measured. The results of many experiments covering a temperature range of 0° to −50° C and supersaturations varying from a few per cent to about 300 per cent (in very clean, droplet-free air) consistently showed the crystal habit to vary along the length of the fibre in the following manner: 0° to −3° C, thin hexagonal plates; −3° to −5° C, needles; −5° to −8° C, hollow prisms; −8° to −12° C, hexagonal plates; −12° to −16° C, dendritic stellar crystals; −16° to −25° C, hexagonal plates; −25° to −50° C, hollow prisms. These changes of habit were controlled almost entirely by the temperature, the supersaturation influencing only such secondary features as the growth-rate and the onset of dendritic and needle growth. Similar conclusions have been reached by Kobayashi[2].

In attempting to account for these changes of habit, considerable interest is attached to recent reports by Isono *et al.*[3,4] that they are further modified if the crystals are grown in an atmosphere of hydrogen instead of air, but that little change is effected by replacing air with carbon dioxide. In particular, Isono found that crystals grown in a water-saturated air at −7° C developed preferentially along the *c* axis to form hexagonal prismatic columns; but, in hydrogen, the growth-rates in the *a* and *c* directions were approximately equal. Furthermore, needle-like crystals grown in air thickened, and skeletal growth was suppressed when the air was replaced by hydrogen. Crystals grown at −16° C in air took the form of thin hexagonal plates, but those grown in otherwise similar conditions in hydrogen developed as thick plates and short hexagonal columns.

In general, the effect of hydrogen was to produce more nearly isotropic growth and isometric crystals, changes which were attributed to the high diffusion coefficient of water vapour in hydrogen, it being 3.4 times that in air. The fact that crystals grown in carbon dioxide were very similar to those grown in air at the same pressure was taken to be consistent with the diffusivity being only 0.7 times that in air.

If the rate of diffusion of water vapour were an important factor in controlling crystal habit, very similar results to those obtained in hydrogen should be obtained in air at reduced pressure since the diffusivity is inversely proportional to the air pressure. Indeed, Kobayashi[2] and Isono[4] report that reduction of the air pressure does influence the shapes of crystals grown in both diffusion- and mixing-cloud chambers.

Isono found that his results obtained at −7° and −16° C in hydrogen were reproduced in air at pressures of 80–20 mm mercury. Kobayashi reports that the hexagonal plates and dendritic crystals found at temperatures between −10° C and −20° C in air at normal atmospheric pressure persist if the pressure exceeds 300 mm., but, at less than 100 mm. pressure, they are entirely replaced by hexagonal columns, often with hollow cavities, and, at less than 70 mm. pressure, by short solid columns which now occur at all temperatures between 0° C and −30° C. Unfortunately, under the conditions of the experiment, the total pressure could not be lowered without also lowering the supersaturation of the vapour, and Kobayashi attributes the formation of solid prismatic columns at low air pressures to the slow growth conditioned by the low supersaturation. He supports this view by recording that in air at normal atmospheric pressure only solid columns are obtained in

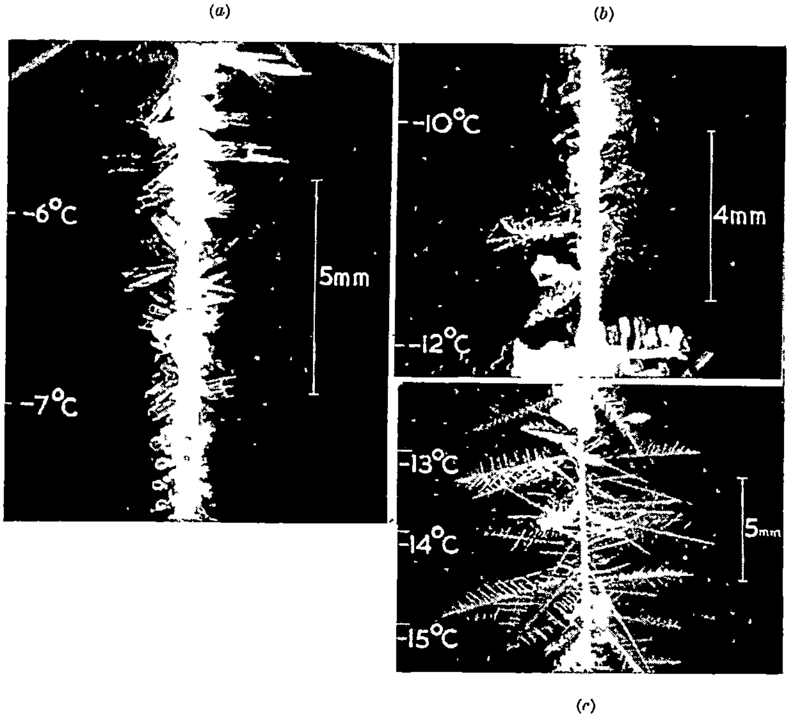

Fig. 1. Ice crystals growing in an atmosphere of hydrogen on a fibre suspended in a diffusion cloud chamber

a, Needles and hollow prisms in the temperature range −5° to −7.5° C; *b*, plates between −9° and −12° C; *c*, dendrites between −12° and −16° C

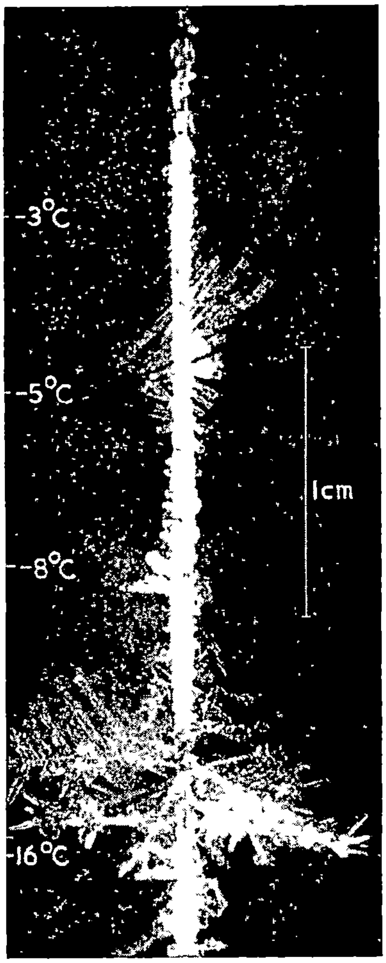

Fig. 2. Crystals grown in air at 80 mm. mercury pressure. The sequence is plates → needles → hollow prisms → plates → dendrites → plates as the temperature varies from 0° to −20° C.

the temperature range 0° to −30° C. providing the supersaturation does not exceed 7 per cent with respect to ice.

Because the results of these Japanese experiments in hydrogen and in air at low pressure, if confirmed, might throw new light on the mechanism responsible for the remarkable habit changes in ice, similar investigations have been made by us.

The crystals were grown, in aerosol-free air, in the diffusion cloud chamber described by Hallett and Mason[1]. They were supported on a fine fibre along which the temperature varied from 0° to −50° C. and the supersaturation could be varied and measured over a wide range. In a chamber filled with hydrogen at atmospheric pressure, the crystals exhibited the same variation with temperature as listed above for crystals grown in air (Fig. 1). No differences were observed except that the crystals grew much faster in hydrogen, in conformity with the diffusion coefficient of water vapour being 3·4 times that in air, and the thermal conductivity, which controls the rate of dissipation of the latent heat of crystallization, being about seven times greater.

Crystals were also grown under reduced air pressures of 300, 150, 80, 40 and 20 mm. mercury, the pressure never varying by more than 1–2 mm. during the course of any one experiment. Again, as shown in Fig. 2, the habit varied with temperature in a manner identical to that observed at normal atmospheric pressure and dendritic forms could always be produced between 0° C. and −3° C., and also between −12° and −16° C., at high supersaturations.

Crystals were grown under low supersaturations at atmospheric pressure between two parallel sheets of ice maintained at slightly different temperatures. This arrangement allowed the temperature and supersaturation to be accurately determined. Under supersaturations not exceeding 5 per cent with respect to ice, plate and sector-plate crystals appeared in the temperature range −10° to −15° C. and therefore the experiments provided no support for Kobayashi's claim that only solid prismatic columns occur at all temperatures between 0° C. and −30° C. at such low supersaturations.

Summarizing, we have been unable to confirm that the habit of ice crystals grown from the vapour is essentially modified by growing them in either hydrogen or in air at reduced pressure, although their growth-rates are affected in the sense one would expect from the manner in which the diffusivity and thermal conductivity of the environment would influence the fluxes of water vapour and heat.

We are unable to offer an explanation of the results obtained by the Japanese workers except to suggest that, perhaps, their apparatus may have been contaminated with small traces of foreign vapours such as are known[5] to affect markedly the ice-crystal habit even though present in only very small quantities.

CELL-WALL MUCOPEPTIDES OF *STAPHYLOCOCCUS AUREUS* AND *MICROCOCCUS LYSODEIKTICUS*

By H. J. ROGERS and H. R. PERKINS
National Institute for Medical Research, Mill Hill, London, N.W.7

A CONSIDERABLE number of recent studies have been concerned with the superficial layers of micro-organisms. In particular, insoluble material which is resistant to the action of several proteolytic enzymes and nucleases has been isolated. The morphology of this material is such that it may be regarded as consisting of the cell walls. Lysozyme-sensitive micro-organisms yield walls which are dissolved by lysozyme. In Gram-positive species the material has a relatively simple overall chemical composition compared with that of the cytoplasmic proteins, and its biosynthesis is inhibited by antibiotics such as penicillin and bacitracin. Elucidation of the more detailed chemistry of the structure and biosynthesis of the cell wall holds, therefore, the hope of a further understanding of the mode of action of antibiotics The purpose of the present article is to discuss some recent observations made in these laboratories and elsewhere in relation to concepts about the structure and biosynthesis of the cell walls of, in particular, staphylococci and micrococci

The work of Salton[1] and Cummins and Harris[2] firmly established that a large proportion of the substance of cell walls of representative strains of several species of Gram-positive cocci, other than some streptococci, consists of a limited number of amino-acids, two amino-sugars and sometimes one or two hexoses, these component substances were detected on paper chromatograms of acid hydrolysates of the wall structures The name mucopeptide[3] has more recently been proposed to describe the group of polymeric substances containing these compounds The earlier work was not designed to give an exact indication of the quantitative interrelationship between the components or to express any attitude towards the number of polymers combined to give the final insoluble wall structure Suggestions of possible heterogeneity at the polymer-level were, however, contained in the earlier work of Mitchell and Moyle[4], who had isolated from a cell fraction they called "cell envelopes", polyol phosphate compounds Cell walls prepared by the Salton and Horne[5] method were known to contain small amounts of phosphorus, and later Baddiley[6] and his colleagues first obtained substances which they called teichoic acids from *Lactobacillus arabinosus* One component of teichoic acid associated with the wall structure was polyribitol phosphate carrying in covalent linkage either glucose or N-acetylglucosamine to which, in turn, alanine was bound in ester linkage This type of substance was shown to be present in cocci[6] Its amount varied from negligible quantities in walls from *Micrococcus lysodeikticus* to about 30 per cent in the strain of staphylococcus wall examined, these quantities were deduced from the phosphorus contents of the walls—only a small proportion of the calculated material is recorded as having been isolated Mitchell and Moyle[7] have recently shown that their polyol phosphate also contains ribitol phosphate The presence of substances of this type which can be extracted by cold trichloroacetic acid may explain the report[8] of the presence of components soluble in trichloroacetic acid and in water in frozen dried wall preparations

The homogeneity or heterogeneity of the structure remaining (that is, the mucopeptides) after the removal of teichoic acid is still unjudged Examination of the concentration of amino-acids in the mucopeptides from various strains of staphylococci and micrococci shows that considerable differences in the molecular proportions occur Moreover, the ratios for most of the strains do not fit any simple pattern Even if the small amounts of alanine present in the teichoic acid in walls from some strains cause some distortion of the values for the concentration of this amino-acid in the mucopeptide, such considerations do not apply to the other amino-acids Park and Strominger[9] have suggested that a uridine–muramic acid peptide originally isolated by Park[10] from penicillin-treated staphylococci may be a biosynthetic precursor of mucopeptide This peptide had its amino-acids (alanine, glutamate and lysine) in simple molecular proportion and resembled in this respect the wall mucopeptide If this compound should eventually prove to be a precursor, then presumably other precursor compounds corresponding to the glycine and glucosamine present in the wall must be found The molecular ratios for the amino-acids in other strains of staphylococci or micrococci such as 11, 524 or *lysodeikticus* are not simple and the condensation of a single small peptide could not account for them If, however, there is more than one mucopeptide in the wall and possibly a multiplicity of uridine peptide precursors, as has been suggested by Ito, Ishimoto and Saito[11], then this situation is more easily explained

Table 1 AMINO-ACID COMPOSITION OF CELL WALLS EXPRESSED AS MOLAR RATIOS (GLUTAMATE TAKEN AS 1.0) IN SEVERAL STRAINS OF STAPHYLOCOCCI AND MICROCOCCI

M lysodeikticus	1.0	1.9–2.5	1.2–1.6	1.0	13

Cell walls prepared by the Cummins and Harris method, hydrolysed for 4 hr with 4 *N* hydrochloric acid and the contents of amino-acids determined (ref 13)

The action of lysozyme on a 'staphylococcus' strain 11 has provided some facts which also point towards possible heterogeneity of the wall mucopeptides This organism has a wall which is qualitatively similar to staphylococci, as can be seen from Table 1, although it is distinguished by a very low glycine content No glucose could be detected Its cytochrome composition, however, is different from other staphylococci and nearer that of *Micrococcus lysodeikticus* (Jackson, private communication)

Fig 1 shows the lysis of whole organisms of this strain by lysozyme When the enzyme is allowed to hydrolyse wall preparations, the optical density of the suspension falls to about 26 per cent of the

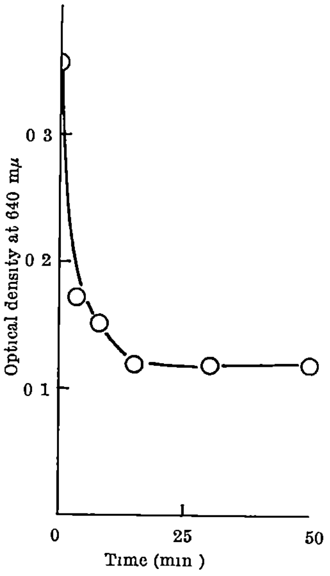

Fig 1 Lysis of 'staphylococcus' strain 11 by lysozyme A suspension of organisms grown in broth for 18 hr at 35° with agitation was prepared by centrifuging, washing twice with water, and suspending in 0.1 *M* ammonium acetate buffer *p*H 6.0 To the suspension warmed to 37° 50 μgm /ml of crystalline (Armour Products, Ltd) lysozyme were added at zero time The optical density was measured at the times indicated during incubation at 37°

Table 2 AMINO-ACID AND GLUCOSAMINE CONTENTS (EXPRESSED AS MOLAR RATIOS WITH GLUTAMATE AS 1 0) OF THE LYSOZYME SOLUBLE AND LYSOZYME INSOLUBLE PARTS OF THE CELL WALL MUCOPEPTIDES OF 'STAPHYLOCOCCUS' STRAIN 11

† Estimated from a comparison of the ninhydrin colour on chromatograms when compared with that given by standard amounts of glucosamine

initial value during 24-hr incubation at 35° Nevertheless, on centrifuging at 10,000*g* for 10 min only about 40 per cent of the material in the hydrolysate remains in solution Table 2 shows the molecular composition of the soluble and insoluble parts More definite evidence of heterogeneity has been demonstrated in walls from *B subtilis* (Janczura and Rogers, unpublished observation)

These walls contain many more amino-acids than those in staphylococcus[1], but lysozyme liberates soluble material from them containing principally alanine, glutamate, diaminopimelic acid, glucosamine and muramate but leaves behind as a small insoluble residue material containing eleven or twelve amino-acids Biochemical heterogeneity of this type may well reflect the multiple-layered nature of the cell wall which has been revealed by electron microscopic examination of sectioned bacteria[12] It is with the possibility of heterogeneity of mucopeptides in mind that the following structural and biosynthetic results must be interpreted

Structural Observations

Hydrolysis of M lysodeikticus wall Brief hydrolysis of walls from *M lysodeikticus* for 20 min with 2 *N* sulphuric acid at 100° has yielded[13] three fragments, one of which (*a*) contains muramate and the four amino-acids, while two have relatively simple composition, one (*b*) contains amino-sugars in the proportion of two moles of muramic acid to one of glucosamine, the other (*c*) one mole of glucosamine, one of muramate and one of glycine The amino-group of the glycine in compound (*c*) is not free to react with fluorodinitrobenzene and it is therefore, reasonable to suppose that the carboxyl of the muramate is linked with the $-NH_2$ group of the glycine As isolated, the $-NH_2$ groups of some of the hexosamine are free, but in the original structure before hydrolysis they are probably acetylated The oligosaccharide (*b*) is different both in its electrophoretic and chromatographic behaviour from the oligosaccharide isolated by Salton[14] from hydrolysates of the wall resulting from the action of lysozyme, as might be expected from the molecular composition of the latter which contains[15] equimolar amounts of N-acetylmuramate and N-acetylglucosamine rather than the two moles of muramate to one of glucosamine present in the acid hydrolysis product

Closer examination of the action of lysozyme on walls of *M lysodeikticus* has revealed certain fallacies in the literature in the interpretation of results It has been recognized since the earliest studies of lysozyme that material reacting in the Elson–Morgan[16] N-acetylglucosamine test is liberated Recently a claim has been made[17] that larger amounts of material reacting as glucosamine rather than N-acetylglucosamine are released Examination[15] of this latter claim has, however, shown that it is likely to be partly due to the reaction of liberated reducing groups from combined N-acetylamino sugars reacting with the free[18] ε-amino groups of lysine to give artefact colour[19] in the test and is not due to hexosamine with free amino groups The reducing group of glucose itself which is also present in the wall of *M lysodeikticus* is not necessarily involved since a similar artefact colour can be obtained from lysozyme digests of walls from the lysozyme-sensitive strains of 'staphylococcus' such as strain 11, in which, as has been shown, no detectable glucose is present

Examination[15] of the colour formed in the N-acetylglucosamine test has revealed a more complicated situation The basis of the test is the heating of the substance in dilute alkali—either sodium carbonate[16] or borate[20], during which heterocyclic ring substances which react to give colour with *p*-dimethylaminobenzaldehyde are formed Examination of the time course of chromogen formation in lysozyme hydrolysates of walls during treatment with alkali reveals that smaller molecular material in them is hydrolysed by alkali under the conditions of hexosamine tests, presumably to give free reacting N-acetylglucosamine and N-acetylmuramic acid groups which are rapidly converted to chromogen Thus, the amount of 'N-acetyl-hexosamine' estimated depends upon the degree of alkaline hydrolysis which has taken place in the test Previous results for liberation of 'N-acetylglucosamine' from cell wall material by lysozyme probably reflect more upon the alkali treatment used in the method of estimation than upon the action of the enzyme itself, no free 'glucosamine' is liberated Oxidation of the disaccharide liberated by lysozyme with hypoiodite followed by hydrochloric acid hydrolysis gave no glucosaminic acid but did give a substance which may be the lactam derived from the C-1 carboxylic acid corresponding to N-acetylmuramic acid, at all events, isolated N-acetylmuramic acid gave the same substance after hypoiodite oxidation and acid hydrolysis[15]

Thus the lysozyme-produced disaccharide accounting for about 15–16 per cent of the total hexosamine in the wall is likely to be 1–4 or 1–6 N-acetylglucosamido-N-acetylmuramic acid This assumes, for the present, that this disaccharide is not a product of a transglycosidation rather than a hydrolysis Other evidence shows the linkage almost certainly to be 1–6 No evidence is yet available about the bond between C-1 of N-acetyl-muramic acid and N-acetylglucosamine, but we may for the moment suppose that part of the mucopeptide or part of one of the mucopeptides is made up of N-acetylglucosaminido-1–6 N-acetyl muramic acid with the carboxyl group of the muramate free and partly of a disaccharide in which this group is combined with glycine

If the larger, more complicated peptide isolated from acid hydrolysates comes from the same polymer, then the rest of the amino-acids may occur as a sequence linked to the glycine This discussion leaves glucose out of account Peptide amino-sugar fragments also containing glucose have been isolated from acid hydrolysates of the cell walls and it seems likely that glucose does not occur in the form of a separate polymer It is very rapidly released[13] during dilute acid hydrolysis of the wall, a behaviour reminiscent of that of fucose in the blood group substances

We have then the following evidence about structures in the wall (1) N-acetylglucosaminido-1-6-N-acetylmuramate occurs to the extent of at least 15 per cent of the total hexosamine (2) Glycyl-N-acetyl-muramido-N-acetylglucosamine or N-acetylglucosaminido-1-6-N-acetylmuramyl-glycine occurs (3) The glycine of (2) may be further linked to a peptide chain containing glutamate, alanine and lysine (4) A lysozyme-resistant[13] structure containing two molecules of muramate and one of glucosamine exists in the molecule (5) Lysozyme so fragments the molecule that the following are formed (*a*) the disaccharide already mentioned , (*b*) at least three substances diffusible through 'Cellophane' which contain both glucosamine, muramate and the four cell wall amino-acids but no glucose , (*c*) three large non-diffusible substances[14] which have some amino-sugar and almost all the glucose associated with them This profound fragmentation of the molecule suggests that the lysozyme labile bond is scattered through the molecules of the polymer or polymers rather than occurring at frequent regular intervals as part of an unbranched backbone mucopolysaccharide chain It is clearly too early to speculate further about the structure of the mucopeptides The optical specificity of the amino-acids in the various fragments has not yet been examined, although it is known that a proportion of the alanine[9,21] and all the glutamate in the walls of some strains of *Staphylococcus aureus* and in *Micrococcus lysodeikticus* is in the -D form

Biosynthesis of Staphylococcal Mucopeptides

Biosynthesis of the mucopeptides is in some respects a less complicated process than that of cell proteins , it can occur under conditions where protein formation will not occur, such as when a single cell wall amino-acid is supplied to the organism[3,22] when chloramphenicol is added to staphylococcal suspensions, thus stopping ordinary protein synthesis[3,22,23], or in *B subtilis* when aza-guanine is present, which also brings to a halt protein synthesis[24] The process of mucopeptide synthesis is, nevertheless, sensitive to penicillin[3,25], whereas protein synthesis is not[26] Even in the presence of penicillin, however, synthesis of cell wall material by suspensions of some strains of staphylococci continues for a time at a reduced rate[3] During this time abnormal mucopeptide is formed, with a smaller content of alanine relative to the amount of glutamate[3] The biosynthesis of the ribitol phosphate teichoic acid is also stopped by penicillin[4,7]

In some strains, but not in others, a uridine muramyl peptide already referred to accumulates[3,9,10] In another strain more complicated uridine peptides accumulate[11], but the walls of the organism were found[27] to be more complicated Whether or not the uridine peptides are precursors of cell wall mucopeptides remains to be proved , that uridine compounds of the amino-sugars should be involved in building up the glycosidic bonds in the structure is eminently reasonable from other work on mucopolysaccharide and polysaccharide biosynthesis, and uridinediphosphomuramate has been reported as being present in other species of organisms[18] Also present within *Streptococcus faecalis*[29] and, as we have shown, within *M lysodeikticus* and *Staphylcoccus aureus*, are larger peptides containing the same hexosamines and amino-acids as the cell wall Amino-acid is incorporated rapidly into some of these peptides (Rogers, H J , and Mandelstam, J , unpublished observations), so they also may play some part in mucopeptide biosynthesis

Table 3 EFFECT OF DILUTION ON THE EFFICIENCY OF A STAPHYLOCOCCAL SUSPENSION IN SYNTHESIZING MUCOPEPTIDE

Mass of organisms added (μgm)	Vol of supernatant	Total counts/min incorporated	Total counts/min mgm D W * × 10^3
0	0 5	57	—
12	0 5	225	14
62	0 5	563	8 1
125	0 5	870	6 5
250	0 5	1,600	6 2
12	0	118	9 8
250	0	920	3 7
1,000	0	1,975	1 9

* mgm D W = mgm dry weight of bacteria added per ml of system

Organisms (*Staphylococcus aureus* strain 524) in suspension and crush supernatant were added to make a final volume of 2 5 ml and final concentrations of 0 5 μmole of ATP and UTP, lysine and glutamate, 1 0 μmole of alanine, magnesium, cysteine and 0 22 *M* sucrose were present Radioactively labelled glycine 1 5 μmoles/ml of glycine were added containing 0 085 μc of radioactivity as ^{14}C , 1 μc of glycine gave 2 09 × 10^5 counts per min in the counting apparatus used the mixtures were incubated for 90 min at 37° and the reactions were stopped by the addition of trichloroacetic acid to a final concentration of 5 per cent (w/v) Purified cell wall (10 mgm) was added as carrier before the trichloroacetic acid at the end of the experiment The samples were then treated as for 'T C A mixed precipitates' (ref 3) The broken suspension was made by crushing the suspension in *M* sucrose containing cysteine, magnesium and phosphate in the Hughes press working at −25° to −30° The broken preparation was then diluted to ten times its initial volume with 0 1 *M* phosphate at *p*H 7 0 and centrifuged for three periods of 15 min at 1,000*g* at 0–4° , between each spinning the sediment was removed The final supernatant was used

In order to further the study of these possible intermediates, it would clearly be desirable to have some system in which the selectively permeable membrane of the living organism is no longer functional Attempts to produce active preparations free of whole living cells similar to those which others have found capable of incorporating amino-acids into cell walls[30,31] have not so far been successful Initial experiments were very hopeful so long as the efficiency of the remaining unbroken organisms was regarded as being independent of the dilution of the suspension and the presence of 'cell sap' As Table 3 shows, however, this is not so, and even when the number of whole cells was not more than 0 05–0 1 per cent of those in the initial cell suspension the incorporating activity was equivalent to 10 per cent of that by the whole unbroken preparation Part of the stimulating activity of the 'cell sap' was shown to be due to its content of nucleic acid (Table 4), a striking parallel with previous observations[30] made with broken cell preparations Some degree of specificity existed, in that nucleic acid isolated by the technique of Jones[32] from the strain of staphylococcus examined was much more effective than thymus deoxyribonucleic acid In another type of experiment, living cells were labelled in their cell walls, added to part of the crush

Table 4 , STIMULATION OF CELL WALL SYNTHESIS BY NUCLEIC ACIDS ISOLATED FROM *Staphylococcus aureus* STRAIN 524

	Total counts/min /mgm added cells × 10^3		
	Mixed TCA ppt Exp 1	Mixed TCA ppt Exp 2	Cell walls Exp 1 and 2
No additions	3 7	3 7	3 7
+ Supernatant	10 7	10 0	9 90
+ Nucleic acid	9 0	9 2	9 30

The conditions for incubation were as described in the legend to Table 3 The supernatant was the same as for the experiment shown in Table 3 and was replaced where indicated by 0 15 mgm /ml of nucleic acid (mixture of deoxyribonucleic acid and ribonucleic acid in the proportions of 7 1) isolated from *Staph aureus* 524 and 50 μgm /ml of cells were added Carrier cell wall was added as previously described (cf Table 3) and cell walls were re-isolated by the Cummins and Harris (ref 2) procedure

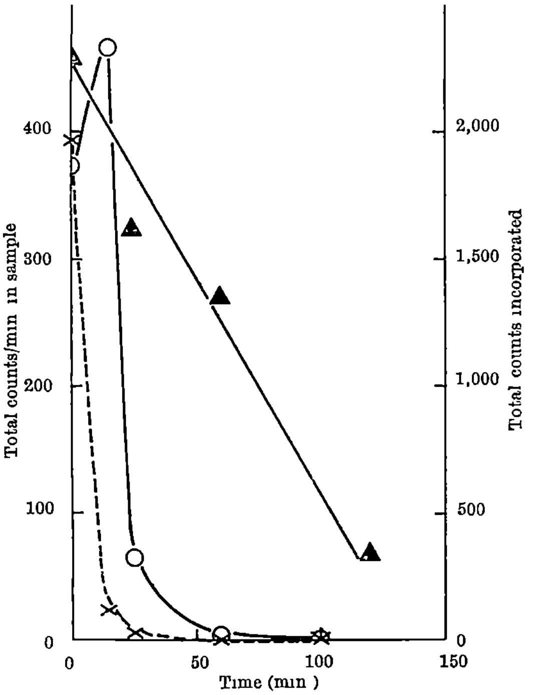

Fig 2 The sedimentation of whole cells from a broken preparation during centrifugation at 1,000*g* at 0–4° Whole cells of *Staphylococcus aureus* strain 524 were labelled in their cell walls by incubation with labelled glycine (ref 22), washed and prepared as a thick suspension which was then added to the diluted crush The crush was prepared from *Staphylococcus aureus* strain 524 by passing a thick suspension of cells in *M* sucrose through the Hughes press working at −30° The crush was then diluted with either 0 1 *M* sodium-potassium phosphate buffer, *p*H 7 0 ×, or with further *M* sucrose (▲) At the times indicated the centrifuge was stopped, and samples taken from the supernatant In order to obtain as representative samples as possible without disturbing the sediment, the pipette was moved slowly down the tube while the sample was drawn into it The samples were mixed with trichloracetic acid to give a final concentration of 5 per cent (w/v) and the precipitate washed once with 5 per cent trichloroacetic acid and dried by washing with acetone and ether The dried precipitates were weighed and assayed for radioactivity at infinite thickness Total radioactive counts (that is, weight × specific activity) are recorded ○ shows the ability of samples of the supernatants to incorporate radioactive glycine into cell wall material when tested under the conditions given in the legend to Table 3

and incorporating activity of the cell wall and residual radioactivity due to whole cells remaining in the supernatant after centrifugation at 0–4° compared. Two observations from Fig 2 can be made (1) that centrifugation at 1,000*g* in the presence of sucrose can be a very inefficient way of removing whole cells , (2) a difference between the rate of deposition of whole cells and the incorporating activity of the preparations is apparent, thus suggesting that incorporation might be taking place into some particle less dense than the whole cell This difference, however, can be largely accounted for by the increasing efficiency of the decreasing number of whole cells

RELATIONSHIP BETWEEN PHOTOPHOSPHORYLATION AND THE HILL REACTION

By Dr H E DAVENPORT

Agricultural Research Council Unit of Plant Nutrition (Micro-nutrients), Research Station, Long Ashton, Bristol

ARISING from the work of Hill[1], it is now well known that isolated chloroplasts illuminated in the presence of a suitable hydrogen acceptor will evolve oxygen

$$2A + 2H_2O \xrightarrow[\text{chloroplasts}]{\text{light}} 2AH_2 + O_2$$

Little doubt now remains that photolysis of water in the Hill reaction with production of reducing power and oxygen represents a partial model of photosynthesis in a cell-free system

Recently, Arnon, Whatley and Allen[2] have made the important observation that when a phosphate acceptor system (adenosine diphosphate, Mg^{2+} and PO_4^{3-}) is included in the Hill reaction system with coenzyme II or ferricyanide as hydrogen acceptor, oxygen evolution is stoichiometrically related to phosphate esterified into adenosine triphosphate Moreover, in the ferricyanide reaction the rate of production of oxygen is stimulated two-fold by addition of the phosphate acceptor

In the present work a similar stimulation of the Hill reaction rate by phosphate acceptors has been observed with coenzyme II as hydrogen acceptor The reduction of substrate amounts of pyridine nucleotides by catalytic amounts of chlorophyll has been shown to require a protein factor readily extractable from chloroplasts[3],[4] A preparation of this factor was obtained from spinach leaves by the method of San Pietro and Lang[4] Chloroplasts were obtained by grinding spinach leaves in 0 4 *M* sucrose containing 0 05 *M tris* buffer *p*H 7 8 and 0 01 *M* sodium chloride The fraction sedimenting between 500 and 1,500*g* was resuspended in the same medium Reduction of added pyridine nucleotide was followed by observing the increase in optical density at 340 mμ after a period of illumination The blank cell contained all the reagents except pyridine nucleotide Fig 1 shows that the reduction of coenzyme II is stimulated 2 5-fold by the presence of the phosphate acceptor system and that all the components of this system are necessary for appreciable stimulation In these experiments, contrary to the findings of San Pietro and Lang[4], coenzyme I was not reduced either in presence or absence of the phosphate acceptor

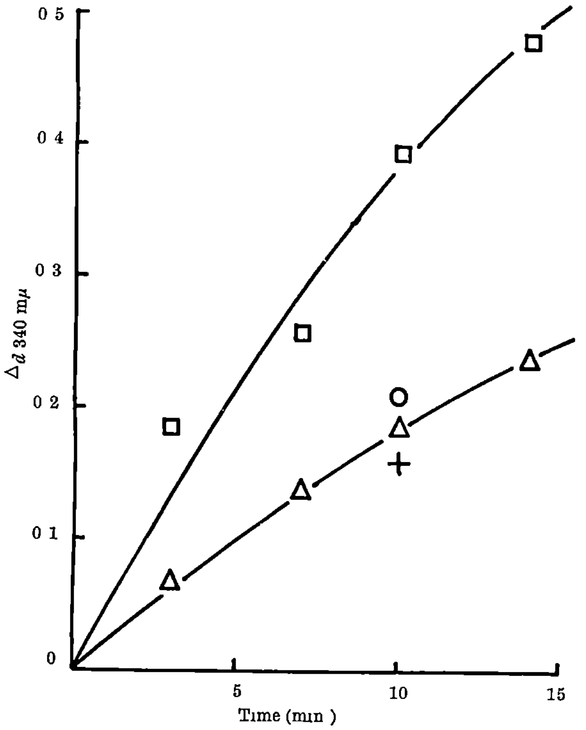

Fig 1 Effect of phosphate acceptor system on the rate of reduction of coenzyme II by isolated chloroplasts The reaction mixture contained, in a final volume of 2 5 ml , leaf protein 0 26 mgm , chloroplasts containing 23 μgm chlorophyll and (except where otherwise indicated) the following in micromoles *tris* buffer, *p*H 7 4, 80 , coenzyme II, 0 5 , adenosine diphosphate, 2 , magnesium chloride, 10 , phosphate buffer, *p*H 7 4, 80 Illumination by 500-watt projector lamp at 1 ft temp 16° □, complete system , O, magnesium omitted , +, adenosine diphosphate and magnesium omitted , Δ, adenosine diphosphate, magnesium and phosphate omitted

Arnon *et al* [3] in their observations on phosphorylation accompanying coenzyme II reduction by illuminated chloroplasts have shown that addition of catalytic amounts of flavin mononucleotide or menadione abolish both oxygen evolution and the accumulation of reduced coenzyme II and stimulate phosphorylation A probable mechanism for this effect suggested itself in the course of the present work All the leaf and chloroplast protein fractions active in mediating coenzyme II reduction were found also to possess a very active coenzyme II diaphorase activity similar to that reported by Avron and Jagendorf[5] Diaphorase in the presence of a rapidly autoxidizable hydrogen acceptor should function as a reduced pyridine nucleotide oxidase Menadione and flavin mononucleotide are listed by Avron and Jagendorf as hydrogen acceptors for their coenzyme II diaphorase from chloroplasts Their effect in reoxidizing reduced coenzyme II produced photochemically by a chloroplast system containing San Pietro and Lang leaf extract is shown in Fig 2 Here also pyocyanine is shown to have a similar

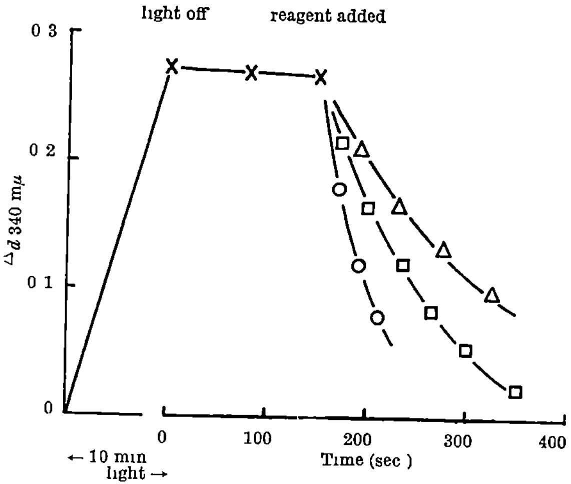

Fig 2 Reoxidation of photochemically reduced coenzyme II by some catalysts of photophosphorylation Reaction mixture as Fig 1 (complete system) At the time indicated 0 05 μmole of the following added Δ, flavin mononucleotide , □, pyocyanine , O, menadione

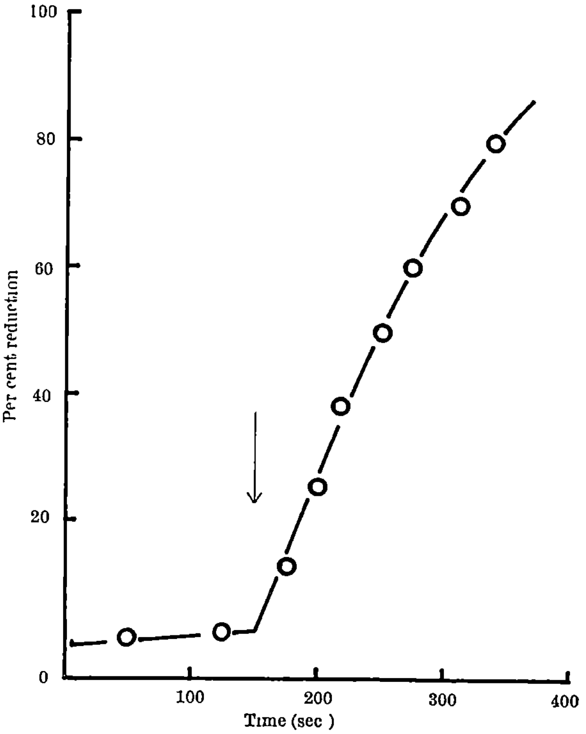

Fig 3 Catalytic effect of pyocyanine in promoting reduction of methæmoglobin by illuminated chloroplasts Reaction mixture contained chloroplasts equivalent to 35 μgm chlorophyll, whale muscle methæmoglobin, 0 35 μmole , phosphate buffer, *p*H 7 4, 150 μmoles and water to 5 ml Pyocyanine (0 05 μmole) added at time indicated by arrow Illumination by 500-watt projector lamp at 1 ft , temp 18°

activity Pyocyanine has been found by Walker and Hill[6] to resemble flavin mononucleotide and menadione as an active catalyst of photophosphorylation It has not previously been recorded as an autoxidizable hydrogen acceptor of the chloroplast diaphorase

These observations suggest that these photophosphorylation catalysts may function by maintaining a level of oxidized coenzyme II in competition with the light-driven reduction of the coenzyme In the intact leaf this level would be maintained by utilization of the reduced coenzyme in carbon dioxide fixation An objection to the concept is that the catalysts stimulate phosphorylation by chloroplasts in the absence of added coenzyme II and leaf extract It has, however, been shown that isolated chloroplasts contain significant amounts of pyridine nucleotides[7] Moreover, in the present work it was found that both the diaphorase and pyridine nucleotide reductase activities remained in association with the chloroplasts isolated in isotonic media Such chloroplasts in conjunction with pyocyanine do in fact bring about re-oxidation of reduced coenzyme II in the absence of added leaf extract

A necessary condition for a mechanism of this kind to function is that the photophosphorylation catalysts should be shown to be reduced by illuminated chloroplasts This was demonstrated indirectly by using the catalysts to couple the reducing power of illuminated chloroplasts to the reduction of methæmoglobin Methæmoglobin is not reduced directly by isolated chloroplasts[8] Fig 3 shows that addition of a catalytic amount of pyocyanine to the system results in a rapid reduction of the hæm-protein It thus appears that the pyocyanine can act as a hydrogen acceptor in the Hill reaction, but in the absence of a further reduction step is rapidly reoxidized by free oxygen or its precursors in the system Similar results were obtained with flavin mononucleotide and menadione

The experimental details of this work will be published more fully elsewhere

STRUCTURE OF α-HYDROXYACETYLENE COMPLEXES OF PLATINUM(II)

By Dr J CHATT, L A DUNCANSON and R G GUY

Imperial Chemical Industries, Ltd , Akers Research Laboratories, The Frythe, Welwyn, Herts

THE best characterized co-ordination compounds containing olefinic hydrocarbons as ligands are those of platinum(II) They were discovered in 1830[1] Nevertheless, corresponding complexes of acetylenic hydrocarbons have proved somewhat difficult to obtain, and their preparation has been reported only recently[2,3] Our study[3] showed that the stability of the complexes depends critically upon the structure of the acetylenic hydrocarbon, $R\,C \equiv C\,R'$ It appeared that the more electronegative and conjugative the nature of the hydrocarbon radicals R and R' the lower the stability of the complexes It is therefore surprising that complexes of the dihydroxyacetylene, $Me_2C(OH)\,C \equiv C\,C(OH)Me_2$ (*ac*), with strongly electronegative hydroxyl groups attached to the α-carbon atoms should form relatively very stable complexes of the types $K[acPtCl_3]$, *cis*-$[ac,NH_3PtCl_2]$ and *trans*-$[ac,\text{amine}PtCl_2]$[4], and so we have prepared a series of complexes of α-hydroxyacetylenes and their methyl ethers, compared their stabilities, and examined their infra-red spectra to see whether the hydroxyl groups contribute in some direct way to the stability of the complexes

The hydroxyacetylenes form complexes of the type $K[acPtCl_3]$ by direct reaction with aqueous K_2PtCl_4 or with $K[C_2H_4PtCl_3]$ in acetone, but up to the present it has not been possible to prepare from these the non-ionic bridged complexes $ac_2Pt_2Cl_4$ On the other hand, the acetylenic hydrocarbons form the bridged complexes directly, and the salts of the type $K[acPtCl_3]$ are usually unstable in water, eliminating potassium chloride and reverting to the bridged complex The methyl ethers form considerably less stable complexes than do the hydroxyacetylenes

In Table 1 we list a representative selection of the complexes of hydroxyacetylenes and their methyl ethers, with pertinent infra-red spectral data

In these complexes the triple bond is co-ordinated to the metal as shown by the lowering of some 200 cm^{-1} in the triple bond stretching frequency ($\nu_{C \equiv C}$) This should be compared with the lowering of 150 cm^{-1} observed in the corresponding olefin complexes[5] It is interesting, too, that the hydroxyl groups are also profoundly modified when the hydroxyacetylenes form complexes, the O—H stretching frequency ($\nu_{O\text{-}H}$) being lowered by 110–140 cm^{-1}, depending on the substituent on the α-carbon atom This fact, and a number of supporting observations which cannot all be presented here, lead us to suggest that the electron pairs on the oxygen atoms in the hydroxy-

and methoxy-acetylenes interact with the vacant $6p_z$-orbital of the platinum atom as shown in Fig 1 Alternatively, in the case of the hydroxyacetylenes, the hydrogen atoms of the hydroxyl groups may interact with electrons in the $5d_{z^2}$-orbital of the metal Thus the unexpected stability of the complexes would arise because the hydroxyacetylenes behave as multidentate ligands, and the platinum(II) atom has a very distorted octahedral configuration such as has been demonstrated[6] in certain complexes of the type $[o\text{-}C_6H_4(AsMe_2)_2]_2PtI_2$

Intermolecular hydrogen bonding between the hydroxyl groups, or a hydroxyl group and a chlorine atom, is rejected as the cause of the lowering in the O—H stretching frequency, because there are no bands which can be assigned to free hydroxyl groups in the spectra of carbon tetrachloride solutions of the complexes, and the spectra of the solutions are unchanged on addition of dioxane Intramolecular hydrogen bonding between the hydroxyl groups and the chlorine atoms is sterically impossible if the triple bond lies perpendicular to the plane of the platinum and chlorine atoms, as does the double bond in the olefin complexes[7,8] In alkyne complexes of the type *trans*-[Bu^t C≡C R,piperidinePtCl$_2$], the N—H stretching frequency (ν_{N-H}) is independent of the group R in the alkyne, having a value[3] of 3,221 cm^{-1} In the hydroxyacetylene complexes it changes considerably as substitution about the α-carbon atom is changed, and especially on methylation of the hydroxyl groups This suggests that there is a route from the N—H bond to the place of substitution other than through the triple bond On the other hand, the N—H frequency (3,228 cm^{-1}) of the corresponding allyl alcohol complex, in which the hydroxyl group would not be expected to interact with the $6p_z$- or $5d_{z^2}$-orbital for steric reasons, is identical with that of the corresponding complex of allyl methyl ether

The stability of the dihydroxyacetylene complexes is highly dependent on the structure of the glycol, RR'C(OH) C≡C C(OH)$R''R'''$ When $R = R' = R'' = R''' = Me$, stable complexes, Na[*ac*PtCl$_3$] and K[*ac*PtCl$_3$], are readily formed, but the introduction of even one hydrogen atom (R = H, $R' = R'' = R''' = Me$) leads to the production of unstable gums, presumably[9] due to oxidation of the —CH(OH)— group to C=O Complexes of acetylenic glycols containing one or two phenyl groups (for example, $R = R'' = Ph$, $R' = R''' = Me$) are less stable and have been isolated as potassium salts but not as sodium salts Hydroxyacetylenes with phenyl groups conjugated to the triple bond, for example, Ph C≡C C(OH)Me_2 and o-HO C$_6$H$_4$ C≡C C$_6$H$_4$ OH-o and the diyne diol Me_2C(OH) C≡C C≡C C(OH)Me_2, also give unstable complexes, which we have not been able to isolate as sodium or potassium salts, but which might be isolated as salts of larger cations[2] Again it appears that absence of conjugation and a high positive inductive effect of the substituent groups favour the formation of stable complexes

HETEROSIS AND THE GENETICS OF COMPLEX CHARACTERS

By WATKIN WILLIAMS

John Innes Horticultural Institution, Bayfordbury, Hertford

HETEROSIS is one of a group of phenomena for which an adequate genetic interpretation has not emerged The group comprises inbreeding depression, hybrid stability or homœostasis, general and specific combining ability, as well as hybrid vigour in its broadest sense In discussing the role of inbreeding and the superior yield of hybrids, Fisher[1] concluded that the removal of deleterious recessives as a result of inbreeding could account for not more than 1 per cent of the improvement in yield in hybrids, and that increases of the order of 20 per cent remained to be explained Interpretations based on the superiority of the heterozygote or 'over-dominance'[2] have not proved entirely acceptable because whenever over-dominance has been investigated using genetic markers, it has not been found generally to occur[3]. In the absence of a clear-cut unifying hypothesis, present-day concepts of heterosis have become surrounded by highly sophisticated escape clauses involving all the known intricacies of gene action.

Heterosis and its allied expressions are properties of quantitative characters, particularly of such characters as yield, stature, viability and reproductive efficiency. That all expressions of this kind are complex interactions between simpler growth processes is immediately obvious, and this common denominator of quantitative characters is frequently referred to in discussions on heterosis. Nevertheless, the implications inherent in the absence of a direct relationship between gene and complex phenotypic expressions are seldom recognized in interpretation.

In one of the first attempts at explaining hybrid vigour, Keeble and Pellew[4] suggested that the inheritance of height in peas could be explained on the basis of two complementary loci each possessing one dominant and one recessive allele. Excess height in the hybrid resulted from the complementarity of dominant alleles from opposite parents, one conditioning length of internode and the other thickness of stem. (Although in certain circumstances thickness of stem may contribute to stature in plants, it should be noted that the components mostly directly concerned with height are internode length and internode number. This, however, does not affect the principles revealed by the work.) The genetic interpretation advanced by Keeble and Pellew achieved meaning and simplicity only because of the recognition that stature as a measurable character was not a primary expression of gene function, but resulted from multiplicative interaction on the phenotypic level between components which segregated in a manner suggesting direct genic control. The components of height in this material were not heterotic, and nothing more complicated than dominance was necessary to provide an adequate genetic explanation of the results. This early model of the behaviour of heterotic characters, although widely quoted as a special case, has not been fully explored and understood in later work. Hagberg[5,6], although recognizing a similar system in data on *Galeopsis* under the term 'combination heterosis', considered it could be different from 'transgressive heterosis' in which the hybrid is superior in one or more of the components of growth. In this connexion he neglected the most important aspect underlying Keeble and Pellew's interpretation, namely, that height in the pea remained genetically transgressive only so long as the components of height remained unidentified. The complexity of quantitative characters generally is such that the resolution of ultimate cell processes is a matter of utmost difficulty. In these circumstances, therefore, it is more rational to suspect the unitary nature of the component characters than to attribute hypothetical properties to the genetic system when departures from a complementary model are encountered.

Recent evidence from a study of inheritance of yield in the tomato has indicated that systems basically similar to the model governing height in the pea may be of common occurrence. It seemed, therefore, desirable to inquire how far the large body of experimental fact available concerning heterosis and allied phenomena fits in with a simple genetic system when due weight is given to interactions on the phenotypic level between the components of complex expressions.

Heterosis for Yield in the Tomato

The five characters—number of flowers, date of first flower, average weight of fruit, number of fruit and yield of fruit—were studied in three F_1 hybrids. The parents and their F_1 hybrids were compared using means of thirty replicates set out in randomized blocks.

None of the hybrids exceeded the better parent in any of the characters with the exception of yield per plant. Yield in all three hybrids exceeded the highest yielding parent. Yield when measured as weight is a product of number and weight of fruit, and in two of the hybrids number of fruit equalled the 'mid-parent' while the average weight of fruit was slightly in excess of this value. The third hybrid inherited phenotypic dominance for a high number of fruit from one of its parents but in weight of fruit it was only slightly in excess of the lower parent. Heterosis in the compound character was a product of various levels of expression of the components in the F_1, ranging from dominance of the better parent to a slight excess over the poorer parent. Heterosis, therefore, is clearly a property of the phenotype, and is conditioned by the nature of the association between the unit characters in the parents. When two parents differ reciprocally for two interacting components, and if the F_1-levels compensate one another in such a way that their product is greater than in the parent, heterosis is inevitable. Table 1 gives a simple example showing the consequence of mating reciprocally different parents.

Table 1

	Component *A* fruit number	Component *B* fruit weight	Yield
Parent *X*	3	1	3
F_1 (heterosis for yield)	2	2	4
Parent *Y*	1	3	3

The genetic system in the above model is one of blending inheritance, and it is difficult and unnecessary to envisage the operation of the remotest form of interaction on the genetic level. The genes or gene products controlling average weight and number of fruit need not and probably do not interact in the sense that an enzyme and a precursor might interact in a synthesis. Complex characters such as yield can be based on units of the genetic system which act completely independently of one another. Interaction occurs on a higher level of organization, among the components of the phenotype. Thus to interpret hybrid vigour in terms only of gene interaction is a basic misconception which has contributed greatly to the present confused state of the subject.

The system described in the tomato has wider application as can be seen from investigations on the inheritance of yield in wheat[7]. Yield of grain and the component characters weight per grain, grain per spikelet, spikelets per ear, ears per plant, were studied in all possible crosses between four varieties. None of the components showed heterosis, and their levels in

F_1 hybrids were on average slightly in excess of the 'mid-parent' Owing to the small number of comparisons possible in a 4 × 4 diallel cross, one cannot determine with any degree of certainty whether the excess was real Grain yield in all crosses was heterotic, the average yield of the parents and F_1 families was 31 9 ± 0 76 and 37 7 ± 1 02 respectively The authors interpreted this behaviour as being the result of multiplicative as distinct from additive gene action, and concluded "it can be said with confidence that gene interaction plays a part in determining the control of this character" It now seems doubtful whether an interpretation based exclusively on genetic considerations was entirely justified

Detailed examination of the individual wheat crosses shows that all six parental combinations possessed varying patterns of inequality such as was described for the tomato hybrids Four of the six were reciprocally different for all four components Since the component-levels in the hybrids were close to, or slightly in excess of, the 'mid-parent', heterosis for grain yield was inevitable In wheat, as in the tomato, an essentially additive genetic system conditions a multiplicative somatic basis to yield which, when analysed as a simple character, leads erroneously to a non-additive genetic interpretation

In a further study on heterosis among 153 hybrids in a diallel cross of 18 inbred lines of the tomato[8], further aspects of heterosis have been revealed which are relevant to this discussion First, in certain crosses heterosis has been found for yield components such as number of fruit, and this is interpreted as evidence that the component itself may be a product of sub-units Secondly, heterosis for both yield and its components was expressed only in hybrids between the poorer parents Hybrids involving the best parents were inferior to the high parent in the crosses The best varieties possess optimal levels in the yield components whereby maximal yields are achieved The highest levels of yield in the tomato can be expressed in homozygotes There is therefore no advantage for an inbreeding species such as the tomato in heterozygosity *per se* Thirdly, the components, number and weight of fruit, are negatively correlated, $r = -0\ 66$ ($n = 18$) and $-0\ 70$ ($n = 153$) in the parents and hybrids respectively This implies that in the course of the production of a certain finite weight of fruit, a variety producing large numbers will have small fruit and vice versa The maximal level at which each single component can function separately is far in excess of what can be achieved by their product The phenotype cannot sustain the production capacity that potentially resides in the multiplicative relationships between maxima at each of the unitary divisions of a complex expression When the limits for the respective functions are pushed too far by selection, or by inbreeding in outbreeders, a physiological breakdown occurs This frequently expresses itself as sterility, reduced viability or susceptibility to disease[9–11], and may be the basis of concepts of physiological limits[12]

Heterosis and Inbreeding Depression

Inbreeding is invariably associated with loss of vigour in cross-fertilizing species The commonly accepted explanation for this behaviour is based on the dominance hypothesis, and on the segregation of homozygous genotypes The extent of the average depression in a randomly breeding population where there is no selection depends only on the relative difference in expression between the segregating dominant and recessive alleles A genetic system which is strictly additive in expression cannot account for average inbreeding depression because, in the absence of selection, gene frequencies remain unchanged and the mean of the inbred population is therefore unaltered This appears at first sight to exclude the possibility of commonly occurring systems such as were described for tomato and wheat being concerned in inbreeding depression

The dominance hypothesis, despite the fit to average values of inbreeding, presents to my mind one unattractive feature Correspondence between experimental evidence and the dominance hypothesis centres around progeny averages, and the drop in vigour is related to the frequency of the homozygous recessive which after about five generations of selfing will be approaching the limit of $\frac{1}{2}$ at each locus The homozygous dominant will also have the same frequency, and for n loci the frequency will be $(\frac{1}{2})^n$ The failure in practice to isolate vigorous homozygous dominants has, on the dominance hypothesis, been attributed to the size of n and to linkage A purely mechanistic explanation of this kind is not entirely acceptable for the interpretation of a vital process Furthermore, in view of the thousands of inbred lines that have by now been studied in maize, it is inconceivable that chance recombinants of near maximal expression would not have appeared if the cause was one merely of permutation It must also be noted in this connexion that the chance of isolating recombinants will depend not on the potential n, but on that portion which is heterozygous In crop plants such as maize in which some form of selection for vigour has been practised for centuries, the number of unfixed loci may be fewer than is generally assumed in attempts to make the dominance hypothesis acceptable It may be prudent, therefore, to explore other possible factors of causality

The negative correlation between the components of complex expressions and the concept of physiological limit may provide the missing factor necessary to explain inbreeding depression in terms of additive genetic factors Selection experiments already mentioned clearly indicate the undesirable consequences of extremes of selection and of genetic fixation above the optimal level for fitness In terms of the components of fitness, physiological breakdown means that the tolerance-level of the product of component interaction has been exceeded Too many components are simultaneously at too high a level A proportion of the genotypes following inbreeding of heterozygotes should also show loss of fitness similar to that resulting from intense selection Multiple homozygotes for hypermorphic alleles segregating after inbreeding represent genotypes where all the components are simultaneously at a high level, and might be expected to belong to a class where fitness is severely reduced They are the equivalent of a highly selected, closed population where sterility, susceptibility to disease or other forms of debilitation are reducing fitness

The elimination of dominants has been demonstrated by Fisher[13] in populations of *Paratettix texanus* in which it was estimated that double dominants were eliminated to the extent of not less than 40 per cent in each generation The mechanism underlying this selective elimination of genotypes is almost certainly physiological and corresponds very closely to the system postulated here to account for inbreeding depression

If, as seems likely from the above considerations, 'compounds' of dominants or of hypermorphic alleles are to a greater or lesser degree self-eliminating in outbreeders, the dominance hypothesis is not the only explanation for inbreeding depression The pattern fits additive gene action equally well

A distinction, therefore, has to be made between gene interaction and the interrelations of the component parts of the phenotype Phenotypic characters may be multiplicative and may consequently show a mutually dependent relationship while the gene system is strictly additive and its units are strictly independent in function Heterosis in complex characters has been shown here to occur in hybrids simply as a result of a reciprocal inequality of independent gene action in the parents Given reciprocal inequality in the levels of component characters in the parents, intermediate levels in hybrids inevitably lead to heterosis in the complex character It appears, therefore, that many of the difficulties that are encountered in the interpretation of heterosis arise out of the failure to recognize the component parts of complex expressions

Multiplicative interaction between adjusted levels of component characters may govern the control of the physiological limit, as is indicated by negative correlations between components of yield in the tomato It is suggested that mal-adjusted, maximal levels of expression in sub-characters may be responsible for inbreeding depression in outbreeding species leading to the self-elimination of genotypes homozygous for several dominant or hypermorphic alleles. Inbreeding depression, like heterosis, may therefore be explained simply on the basis of interactions on the somatic level which are controlled by a complementary, essentially additive genetic system

TURNIP YELLOW MOSAIC VIRUS NUCLEOPROTEIN PARTICLES WITH DIFFERING BIOLOGICAL AND PHYSICAL PROPERTIES

By R E. F MATTHEWS
Plant Diseases Division, Department of Scientific and Industrial Research, Auckland, New Zealand

PREVIOUS work[1] has shown that purified preparations of turnip yellow mosaic virus contain two types of particle One is a nucleoprotein containing 37 per cent of ribonucleic acid within a roughly spherical shell of protein The other is an apparently identical protein containing no ribonucleic acid The nucleoprotein is infectious while the protein is not The ratio of nucleoprotein to protein particles in the preparations is close to 2 1[1,2] The sedimentation patterns obtained in the ultracentrifuge with both these components give no indication of inhomogeneity[1,3]

The value of density gradient centrifugation under equilibrium conditions in strong cæsium chloride solutions for the fractionation of macromolecules has recently been demonstrated[4,5]

We have now found, using sedimentation into dense cæsium chloride solutions under non-equilibrium conditions, that the nucleoprotein particles of turnip yellow mosaic virus fall into at least two classes with respect to density and infectivity

Turnip yellow mosaic virus was isolated from infected chinese cabbage plants by the ammonium sulphate procedure[1] or by differential centrifugation Preliminary tests with whole virus preparations showed that incubation with strong cæsium chloride solutions for 2 hr at room temperature, followed by 14 hr at 4°, had no detectable effect on the infectivity of the virus To avoid anomalous effects due to crystallization or precipitation of the virus at room temperature in the strong salt solutions employed during sedimentation, all manipulations were carried out at temperatures between 4° and 10° C

In the sedimentation experiments 1–10 mgm of a virus preparation in solution in 0 1–0 6 ml water was layered over 3 5 ml of cæsium chloride solution (density = 1 39–1 43) in a 'Lusteroid' tube The samples were then centrifuged for 200–240 min at 32,000 r p m in the Spinco model L preparative ultracentrifuge using the No $39S$ rotor Under these conditions the virus protein component stays in the boundary between the water layer and the cæsium chloride solution The nucleoprotein sediments through the salt solution and resolves into bands which can be located visually by scattered light (Fig 1)

The various components were withdrawn by piercing the wall of the tube with the needle of a hypodermic syringe, and dialysed to remove salt The bands cannot be removed quantitatively by this procedure, but other methods we have tested lead to substantial mixing of closely spaced bands Estimates of relative amounts of material in various bands were based on the ultra-violet absorption curves of the extracted samples Such estimates on duplicate pairs of bands varied by as much as 25 per cent

In preparations of virus made by the ammonium sulphate procedure, two sedimenting bands appear. The faster-sedimenting band (B_2) usually contains 1/5–1/20 as much material as the slower band (B_1) If these two bands are removed and the material from several tubes combined and run again, each band shows a slight contamination with the other on the second run A third sedimentation usually gives material with no observable contamination This result suggests that the bands are not produced by the action of cæsium chloride on a uniform population of particles Both bands give typical virus nucleoprotein spectra, and the nitrogen/phosphorus ratios suggest that both types of particle have the same

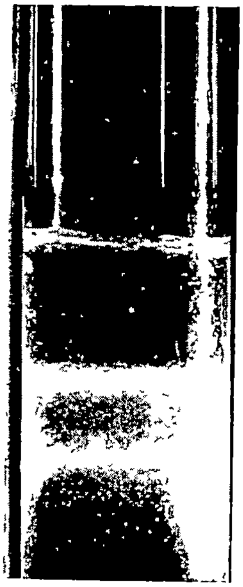

Fig. 1. Fractionation of turnip yellow mosaic virus nucleoprotein in a dense cæsium chloride solution. Of the two nucleoprotein bands appearing in the photograph, the upper (B_1) is infectious, while the lower (B_2) is non-infectious. 4 mgm. of a virus preparation in 0.15 ml. of water was layered over 3.5 ml. of a cæsium chloride solution (density = 1.41). The tube was photographed after 220 min. centrifugation at 32,000 r.p.m. in the Spinco No. 39*S* rotor

content of ribonucleic acid. Solutions of the B_1 and B_2 components equalized with respect to optical density at 260 mμ were tested for infectivity by inoculation to half-leaves of chinese cabbage. The infectivity of the B_2 component compared with B_1 from once-sedimented bands ranged in different experiments from 25 to 6 per cent.

On three times sedimented bands the B_2 material had only 3 per cent the infectivity of B_1. Thus the B_2 band is very probably completely non-infectious. However, to test the possibility that B_1 and B_2 were two different strains of the virus of differing infectivity multiplying together in the plant, four single-lesion isolates were made from plants infected with virus from each band. The isolates were multiplied in chinese cabbage. No symptom differences were observed. Virus isolated by an initial high-speed centrifugation followed by one ammonium sulphate precipitation from each isolate gave a similar band pattern in all cases. The B_2 band was present in about 1/20 the amount of the B_1 band. That virus strains were not involved was confirmed by the production of the B_1 and B_2 bands from a 'necrotic' strain of the virus which is biologically distinct from the type strain.

The B_1 and B_2 bands appear in similar proportions in virus prepared from the same plant material, either by the alcohol–ammonium sulphate procedure, or by differential centrifugation alone. It therefore seems unlikely that either of these bands is an artefact of the procedure used to isolate the virus.

However, in virus material isolated by centrifugation only, a third more slowly moving band (B_0) appears following sedimentation in cæsium chloride. This band is not visible in most ammonium sulphate preparations, and can be largely removed from virus prepared by centrifugation by one ammonium sulphate precipitation. The fact that band B_0 sediments into a cæsium chloride solution of $D = 1.40$ suggests that it must contain some ribonucleic acid. The ultra-violet absorption spectrum and the nitrogen/phosphorus ratio show that the material in the B_0 band contains a lower proportion of ribonucleic acid than the B_1 component and its infectivity is substantially less. However, the B_0 material has not yet been obtained sufficiently free from contamination with B_1 for definitive chemical analysis or infectivity tests.

A detailed study of the serological behaviour of these nucleoprotein components has not yet been made. However, all three give similar virus precipitation end-points (based on the optical density of the solution at 260 mμ) when tested with an antiserum prepared against unfractionated turnip yellow mosaic virus.

The experiments described above suggest that these nucleoprotein components are not artefacts of the purification or isolation procedures, although it may be very difficult to prove beyond doubt that they exist as such in the plant. The ability to fractionate a virus nucleoprotein preparation into infectious and non-infectious classes of particle should be useful for more detailed studies on the inactivation of the virus by various agents. The fact that turnip yellow mosaic virus nucleoprotein as usually prepared is not homogeneous may be particularly relevant for structural studies on the virus, for example, for end-group assays on the ribonucleic acid, where homogeneity of the starting material is an essential prerequisite.

NITRATE REDUCTION BY AQUEOUS EXTRACTS OF EXCISED TOMATO ROOTS

By C. S. VAIDYANATHAN and Prof. H. E. STREET

Department of Botany, University College of Swansea

EXCISED tomato roots are normally supplied their nitrogen as nitrate (45 mgm. N/l.) in a medium of *p*H 4.5–4.8[1]. By substituting ferric ethylenediamine tetraacetate for the ferric sulphate of White's medium, active growth in nitrate occurs over the *p*H-range 4.0–7.2 and in ammonium (4.5 mgm. N/l.) at *p*H 6.8 or above[2]. Nitrite (7.0 mgm. N/l.) at *p*H 6.0–6.8 and glutamine (4.8 mgm. N/l.) at *p*H 6.8 can also function as nitrogen sources for root growth. A preliminary study has now been made of the nitrate-reducing activity of aqueous extracts from excised tomato roots (Best-of-All) grown with these different nitrogen sources and in presence of 0 001 p p m molybdenum

The extracts were prepared by grinding the fresh roots with three volumes of water at 4° C followed by centrifuging at this temperature for 15 min at 600*g* 1 ml of this supernatant was added to 3 ml buffer and the completed reaction mixture adjusted to 5 ml and incubated at 20° C

Nitrite was determined by the sulphanilamide-N-(1-naphthyl)-ethylenediamine hydrochloride method[3], hydroxylamine and hyponitrite by the Czaky modification of Blom's procedure[4] and ammonia by the Conway microdiffusion technique in conjunction with the phenol–hypochlorite method[5] The formation of nitrite from nitrate could be studied since nitrate reduction was not stimulated by addition of manganese whereas reduction beyond nitrite proceeded only very slowly in its absence

Extracts from nitrate-grown roots, in presence of 0 2 *M* orthophosphate buffer (*p*H 7 0), did not reduce nitrate (50 μmoles potassium nitrate) to nitrite in absence of added co-factors or in presence of combinations of molybdenum (0 1 μmole), reduced diphosphopyridine nucleotide (0 3 μmole) and flavin mononucleotide (0 5 μmole) However, the further addition of aldehyde-free ethanol (3 5 m moles), lactate (0 35 m mole), succinate (3 0 μmoles) or glutamate (1 5 μmoles) led to the formation of 5–7 mμmoles nitrite in 3 hr The necessity for these additions and the fact that a further small enhancement of nitrite formation followed the simultaneous addition of 0 8 μmole nicotinamide[7] suggest the presence in the root extracts of a diphosphopyridine nucleotide oxidase[6] By contrast, similarly prepared extracts from 15-day-old tomato seedlings showed the nitrate reductase activity (5 3 mμmoles nitrite/ 3 hr) without the addition of any dehydrogenase substrate

The formation of nitrite by the extract of excised roots in the presence of molybdenum, diphosphopyridine nucleotide, flavin mononucleotide and ethanol began to deviate from linearity within 2 hr although the nitrite content continued to increase for at least 10 hr Activity could be detected over the *p*H range 5 7–8 0 with optimum activity at *p*H 6 5–7 0[8] When tested at 10^{-3} *M*, potassium cyanide caused 90 per cent, and copper sulphate 50 per cent, inhibition of activity , diethyldithiocarbamate, *o*-phenanthroline and 8-hydroxyquinoline were inactive as inhibitors at this concentration 10^{-3} *M* sodium fluoride was slightly stimulatory Omission of molybdenum caused up to 20 per cent reduction in activity

Extracts from excised roots grown for 15 days with ammonium or glutamine as nitrogen sources had barely detectable nitrate reductase activity, whereas, in a simultaneous test, extracts from nitrate- and nitrite-grown roots formed 5 2 and 4 5 mμmoles nitrite, respectively, in 2 hr Similar adaptive formation of the reductase has been reported from work with rice seedlings[9] and wheat embryos[10] It is an essential part of future work to study this adaptive formation in excised roots over the short time periods which have been used in work with leaf fragments[11]

Verhoeven[12] has emphasized that at least three different types of nitrate-reducing systems are known and therefore, in encountering lack of nitrate reduction by excised root extracts in presence of added molybdenum, diphosphopyridine nucleotide and flavin mononucleotide, we tested a number of other combinations of possible electron donors and activating metals This led to the detection of an enzymic reduction of nitrate to nitrite for which ascorbic acid and ferrous iron are essential co-factors Ascorbic acid causes a non-enzymic destruction of nitrite at the high acidity of the sulphanilamide reagent used for the nitrite determination[13] This was reduced by the presence in the reaction mixture of iron and root extract Higher values for nitrite were obtained by addition to the reaction mixture of 100 mgm 'Norit' carbon[14] prior to the nitrite determination, despite the known adsorption of nitrite by this reagent[15]

The standard reaction mixture used in assaying the activity of the ascorbic acid–ferrous iron enzyme system contained, in 5 ml 3 ml 0 2 *M* phosphate buffer (*p*H 7 2), ascorbic acid (1 1 μmoles) ferrous sulphate (0 7 μmole), molybdenum (0 1 μmole), 50 μmoles potassium nitrate and 1 ml root extract Root extracts prepared on separate occasions differed in activity , nitrite formation in 2 hr at 20° C ranged from 3 5 to 8 1 mμmoles Omission of molybdenum reduced activity by up to 15 per cent No activity could be detected with boiled extract or when either iron or ascorbate was omitted, except that ascorbate alone had low activity in presence of 0 3 ml saturated solution of sodium fluoride, possibly due to fluoride inhibition of the dissimilation of endogenous electron donors[16] Nitrite formation did not occur in presence of root extract, buffer and homocysteine, but this latter substance alone among those tested significantly enhanced activity in presence of ascorbate (for example, 0 15 μmole homocysteine raised the nitrite production in 2 hr from 3 7 to 6 5 μmoles)

No results have yet been obtained on which to assess the *in vivo* significance of this ascorbic acid–iron activated system Study of its activity in reduction below the level of nitrite was precluded by the demonstration that ascorbate + iron caused a non-enzymatic destruction of hydroxylamine without formation of detectable quantities of nitrite or ammonium

Using a reaction mixture containing diphosphopyridine nucleotide, flavin mononucleotide (or 0 65 μmole glutathione), 1 5 μmole nitrite, 0 1 μmole manganese and 3 ml 0 2 *M* pyrophosphate buffer (*p*H 7 5) extracts from nitrate- or nitrite-grown roots caused complete disappearance of nitrite in less than 3 hr Only very low activity occurred in absence of added manganese[17] Very little or no ammonium formation accompanied disappearance of nitrite, and the main reduction product appeared to be hyponitrite since it could be oxidized back to nitrite by iodine, and hydroxylamine could not be detected by the *o*-phenanthroline method[18] Extracts prepared from roots grown with ammonium or glutamine as nitrogen sources showed barely detectable nitrite reductase activity

Extracts from nitrate-grown excised roots formed ammonium from nitrite (1 5 μmoles), hyponitrite[14] (1 0 μmole) or hydroxylamine (4 3 μmoles) when both lactate (0 35 m mole), succinate (3 0 μmoles) or formate (6 1 μmoles) and nicotinamide (0 8 μmole) were added to the reaction mixture Only about 30 mμmoles ammonia arose during the complete destruction of the added nitrite Hyponitrite destruction proceeded slowly and extension of the incubation period to 10 hr was required to obtain 20 mμmoles ammonium Hydroxylamine disappeared completely within the 2 hr incubation period but only 30–35 per cent of the nitrogen was recovered as ammonium, suggesting the possible formation of oxime-like compounds

Excised tomato root extracts in presence of added diphosphopyridine nucleotide and flavin mononucleotide can effect reduction of nitrate, nitrite, hyponitrite and hydroxylamino, in agreement with results for *Neurospora crassa*[17,18] The reduction steps beyond nitrite are activated by manganese In this chain the hyponitrite reduction step appears to be rate limiting Roots grown upon ammonium or glutamine have very low nitrate- and nitrite-reducing activities as compared with nitrate- and nitrite-grown roots A thermo-labile system for which ascorbate and iron are co-factors and which *in vitro* effects nitrate reduction is also present

A NEW APPROACH TO THE DATING OF THE DEAD SEA SCROLLS

By Prof D BURTON, M.B E., J B. POOLE and Dr R REED

Department of Leather Industries, The University, Leeds, 2

SINCE their discovery some twelve years ago, the Dead Sea scrolls have attracted considerable interest for the light they may throw upon historical Judaism and Christianity The scrolls, mostly written upon materials derived from animal skin, were found in a number of caves at the edge of the Judaean plateau, a dry and largely infertile region about a mile from the western shore of the Dead Sea The richest collection of manuscripts came from Cave 4, a mere stone's throw from the ruins of a settlement known as Khirbet Qumran

It was early considered that a connexion might exist between the settlement and the scrolls , thus for a number of seasons archæologists excavated the site[1] The oldest levels were of Israelite occupation and dated from the eighth–seventh centuries B C The major part of the finds, however, pointed to an establishment which was probably built in the reign of John Hyrcanus (135–104 B C) and which was elaborated up to 31 B C , when it is thought to have been abandoned following a severe earthquake in Judaea The site lay deserted until the time of Herod Archelaus (4 B C –A D 6), when it was reoccupied by the previous settlers until it was finally destroyed by Roman solders in A D 68 during the first Jewish revolt

Some controversy still surrounds the identification of the settlers, but the majority view[2] is that they were either the Jewish religious sect called the Essenes or another Jewish group having much in common with the Essenes It is generally believed that the scrolls were the property of the settlers, and thus the archæological datings of the occupation of Qumran constitute criteria for dating the manuscripts

The large number of scrolls which have been discovered has also enabled palæographers to trace with greater certainty the evolution of Hebrew script and thus, independently, to date the copying of the manuscripts Briefly, the scrolls cover the period from the late third century B C to the second half of the first century A D , while the manuscripts regarded as peculiar to their owners (for example, the Manual of Discipline) are considered to have first appeared in the middle of the second century B C (ref 3) This latter date corresponds with the time when the Dead Sea community first segregated themselves from their fellow Jews, and also is in substantial agreement with the earliest settlement levels at Qumran However, these majority views have not been universally accepted, and throughout Del Medico[4] has maintained that no direct connexion between the scrolls and the settlement existed Del Medico considers that the scroll caves are deposits (*genizoth*) of books either worn out through extensive use or unacceptable in character to the Jewish authorities If this view is correct, the date of the final abandonment of the settlement obviously could not be used as a guide for dating the scrolls Independently, Sukenik[5] had come to a similar conclusion Furthermore, Driver[6], Teicher[7] and Zeitlin[8], while not acepting the *genizoth* hypothesis, all favour dates later by as much as several centuries than those indicated above

Thus a need still exists for additional methods of dating the scrolls and preferably for those free from the subjective element inherent in the palæographic approach and involving the examination of the chemical and physical nature of the actual scroll materials

No such dating tests on the scrolls themselves have hitherto been made. Linen from Cave 1 and palm wood from the settlement ruins have been dated by the radioactive carbon technique and gave median dates of A.D. 33, with a standard deviation of 200 years for the linen[9] and of 7 B.C. and A.D. 18, each with a standard deviation of 80 years, for the palm wood samples[10]. However, the exactness of this dating technique for archæological purposes is limited and the method can give at best only general confirmation of dates established by other means[11].

The fact that many of the scrolls are made from animal skins, the major fibrous component of which is collagen, affords the possibility of an independent method of dating by measuring the shrinkage temperature of the fragments. Unpublished work from this laboratory has shown that the scrolls are parchments, made mainly from the skins of sheep and of goats. Parchment is made from animal skins which have been unhaired and then allowed to dry under tension, usually by stretching on a wooden frame. The resulting material is durable and needs no further chemical treatment, though often, for writing purposes, the surface is made smooth by mechanical means. Thus the making of parchment is quite distinct from that of leather, where the unhaired skin (pelt) is stabilized by treating it chemically with a tanning agent. Skins processed as parchment may last for very long periods provided they are kept dry. Indeed, this is the reason why the Dead Sea scrolls are still in existence. Any degenerative changes occurring in the collagen fibres present in dry parchments are thus likely to be due mainly to the passage of time. Moreover, these changes should be reflected in a lowering of the shrinkage temperature of the collagen fibres. Accordingly, the shrinkage temperatures of a number of scroll fragments were compared with those of other parchment-like materials of known age, in an attempt to establish a correlation between age and shrinkage temperature. The materials studied were:

Group *A*. English parchments covering the period 1193–1955 A.D. Supplied by the Public Records Office, the Chapter Library of Canterbury Cathedral, Dr. M. L. Ryder, Wool Industries Research Association, Leeds, 6, and Mr. T. H. Gardner, of Ampthill, Beds.

Group *B*. Parchments from the Wady Murabba'at caves, dating from the second Jewish revolt, A.D. 132–135.

Group *C*. Scroll fragments from Cave 4, Qumran. These and the Murabba'at fragments were supplied by the Department of Antiquities, Hashemite Kingdom of Jordan, and by Mr. J. M. Allegro, University of Manchester.

Group *D*. Egyptian Aramaic letter fragments of the fifth century B.C., supplied by the Bodleian Library, Oxford.

Group *E*. Egyptian raw hide axe-hafting, c. 1300 B.C., supplied by the Department of Egyptian Antiquities, British Museum.

The shrinkage temperatures were determined by the method of Borasky and Nutting[12] as slightly modified by Gill[13]. Small samples of the materials were rehydrated for 1 hr. in distilled water and small fibres teased from them, before mounting (between circular cover slips) on the heating stage of the microscope. Heat was applied at a constant rate (2 deg. C./min.) and, so far as possible, fibres of similar size were used. The shrinkage temperature was taken as being that at which the fibre first began to shrink.

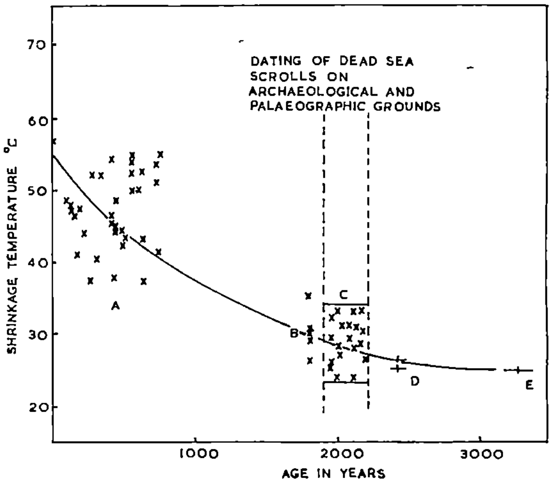

Fig. 1

Usually the mean of three determinations was taken for each material, and the results are shown in Fig. 1.

As regards their shrinkage temperatures, the scroll fragments lie closer to the older samples in groups *B*, *D* and *E* than to the relatively modern parchments (group *A*), which all show higher values. Hence it is likely that the scroll fragments are indeed old and that they are slightly older than the Murabba'at samples, the age of which is well authenticated. Moreover, it is unlikely that the scroll material dates from medieval times, as Zeitlin[8] has suggested. The present findings on the date of the scrolls are thus in general agreement with the assessments based on archæological, palæographic and radioactive-carbon studies. One could be more certain of the usefulness of shrinkage temperature as a guide to age if more parchments older than A.D. 1200 were available for study; but such samples are very difficult to obtain. It should be emphasized that this method of dating necessarily only gives a general guide to the date at which the scroll materials themselves were processed from animal skins. It throws no direct light on the dates at which the scrolls were copied and deposited in the caves.

We wish to thank the Department of Scientific and Industrial Research for providing a special grant for this work; also those people who have kindly supplied us with the various samples.

FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

Monday, October 12

Institution of Electrical Engineers (at Savoy Place, London, W C 2), at 5 30 p m —Discussion on "Is the Present Pace of Electrical Progress Good for the Community ?"

Society of Chemical Industry, Surface Activity Group (at 14 Belgrave Square, London, S W 1), at 5 30 p m —Dr Chas M Blair "The Resolution of Petroleum Emulsion"

University of London (in the Anatomy Lecture Theatre, University College, Gower Street, London, W C 1), at 5 30 p m —Prof C D O'Malley (University of California Medical School) First of three lectures on "Andreas Vesalius—The Development of a Scientist" (Further lectures on October 14 and 15)*

Bee Research Association (in the Meeting Room of the Zoological Society of London, Regent's Park, London, N W 1), at 6 30 p m —Dr F G Smith "Bees and Beekeeping in the Tropics", illustrated by a colour film "Tanganyika Beeswax" 8 p m —Prof G F Townsend "The Activity of Royal Jelly Against Leukaemia and Ascitic Tumours"

Royal Institute of Chemistry, London Section (joint meeting with the Ewell County Technical College Faraday Society, at the Ewell County Technical College, Reigate Road, Ewell, Surrey), at 7 p m —Dr A T James "Gas Phase Chromatography"

Tuesday, October 13

Physical Society, Low Temperature Group (at the Royal Institution, Albemarle Street, London, W 1), at 4 p m —Dr H London "Superfluid Helium" (First Simon Memorial Lecture)

Institution of Electrical Engineers, Measurement and Control Section (at Savoy Place, London, W C 2), at 5 30 p m —Prof A Tustin "The Relationship of Physical Mechanisms to Psychological Processes" (Chairman's Address)

Society of Chemical Industry, Food Group (joint meeting with the Chemical Engineering Group, at 14 Belgrave Square, London, S W 1), at 6 15 p m —Mr G C Eddie and Mr S Forbes Pearson "Engineering Aspects of Recent Research Projects in the Preservation of Fish"

British Association for the Advancement of Science in association with Granada TV Network (at the Guildhall, London, E C 2), at 8 30 p m —Sir Edward Appleton, F R S First of the Inaugural Series of The Granada Lectures on the theme of "Communication in the Modern World"

Wednesday, October 14

British Coal Utilisation Research Association (at the Institution of Civil Engineers, Great George Street, London, S W 1), at 5 30 p m —Sir Eric Rideal, F R S "Coal—a Colloid and a Chemical" (Eighth Coal Science Lecture)

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, London, W C 2), at 6 p m —Discussion on "Graduate Training in Industry", opened by Mr W H Taylor

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Mr H Desmond Carter "The Engineer, Life and Diesel Engines" (Presidential Address)

Society of Chemical Industry, Corrosion Group (at 14 Belgrave Square, London, S W 1), at 6 p m —Mr K H R Wright "Fretting Corrosion"

Thursday, October 15

Society of Chemical Industry, Corrosion Group (joint meeting with the Iron and Steel Institute, at 14 Belgrave Square, London, S W 1), at 2 p m —Discussion of the 6th Report of the B I S R A Corrosion Committee

Institution of Mining and Metallurgy (at the Geological Society of London, Burlington House, Piccadilly, London, W 1), at 5 p m —Scientific Papers

Linnean Society of London (at Burlington House, Piccadilly, London, W 1), at 5 p m —Dr C R Metcalfe "A Botanical Visit to the West Indies", Dr Norman K B Robson "Iter Zambesiacum 1958–1959"

Institution of Electrical Engineers, Utilization Section (at Savoy Place, London, W C 2), at 5 30 p m —Mr T E Houghton "The Electrical Engineer and the Heavy Chemical Industry" (Chairman's Address)

Illuminating Engineering Society (at the Royal Institution, Albemarle Street, London, W 1), at 6 p m —Sir Lawrence Bragg, F R S "The Nature of Light" (Golden Jubilee Lecture)

Society of Chemical Industry, Road and Building Materials Group (at 14 Belgrave Square, London, S W 1), at 6 p m —Dr E D Tingle and Mr N Wright "An Investigation of the Weathering of Road Tar in Open Textured Surfacing", Dr J R Dewhurst "An Investigation of the Setting of Road Tar in Surface Dressing"

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W 1), at 7 30 p m —Sir William MacArthur, K C B , D S O "The Identification of Some Pestilences of the Past" (Presidential Address)

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Scientific Assistant (with a biological degree, the ability to write correct English, and preferably some knowledge of foreign languages) for work which includes the abstracting and reviewing of biological literature—The Director, Commonwealth Bureau of Plant Breeding and Genetics, School of Agriculture, Cambridge (October 15)

Scientific Officer (male, with a first- or second-class honours degree in physics or chemistry, and preferably some experience of polymers or biological systems, or ionizing radiation), at the Royal Military College of Science, Shrivenham, Wiltshire, for a two or three years' programme of fundamental research (of an academic character and intended for publication) on effects of high energy radiation on polymers in solutions, and an Assistant Experimental Officer or Assistant (Scientific) (with a qualification in physics or chemistry at G C E 'A" level, or alternatively some laboratory experience) for work on the same programme—Technical and Scientific Register (K), Ministry of Labour and National Service, 26 King Street, London, S W 1, quoting A 410/9A (October 19)

Gordon Craig Fellow (graduate in medicine) in Urology in the Department of Surgery at the University of Sydney and in the Department of Urology at the Royal Prince Alfred Hospital—The Professor of Surgery, The University, Sydney, Australia (October 23)

Lecturer or Assistant Lecturer in the Department of Education—The Registrar, The University, Leeds 2 (October 24)

University Tutor or Assistant Lecturer in Microbiology—The Secretary, The Queen s University, Belfast (October 30)

Lecturer or Assistant Lecturer in Pure Mathematics—The Registrar, The University, Leeds 2 (October 31)

Lecturer (with an honours degree of a British university and appropriate teaching experience) in Philosophy at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Hong Kong, November 6)

Lecturer (preferably with qualifications in stratigraphical and structural geology) in Geology at the University of Sydney, Australia —The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, November 7)

Scientific Officer (with a good honours degree, and preferably with postgraduate experience and an interest in soil zoology) in the Entomology Department—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (November 14)

Senior Demonstrator (with experience in physical chemistry), and a Laboratory Technician (with experience in physical chemistry) in the Department of Chemistry, University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (November 14)

Lecturer in Pathology—The Secretary, The University, Edinburgh (November 15)

Lecturer (preferably with special qualifications in biometry or biochemistry and physiology or mycology and plant pathology) in Botany at the University of Tasmania—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, November 30)

Mycologist (with a good honours degree in botany with mycology as a special subject, and a knowledge of the more fundamental aspects of animal and human mycoses), at the Commonwealth Mycological Institute, Kew—The Secretary, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Bucks (November 30)

Senior Research Fellow (with a postgraduate degree or research experience in the biochemistry or immunology of parasitic infections) in Immunology—The Registrar, University of Queensland, St Lucia, Brisbane, Queensland, Australia (December 1)

Entomologist (with a good honours degree in zoology, with at least two years' postgraduate experience or training in agricultural entomology) in the Department of Agriculture, Nyasaland, to control crop pests—The Department of Recruitment, Colonial Office, London, S W 1, quoting BCD 63/4/016

EXPANSION OF EDUCATIONAL AND TRAINING FACILITIES IN BRITAIN

WHEN moving the second reading in the House of Lords on April 28 of the Factories Bill, which amplifies and amends the Factories Act, 1937, the Earl of Dundee pointed out that it empowered the Minister, under Clause 25, to improve his advisory services by the collection of information, the investigation of problems of health, safety and welfare, including the establishment of laboratories not only for research but also, as Mr Ian MacLeod had explained in the House of Commons, for wider purposes and the dissemination of the results to industry The Bill, in fact, constituted a new departure in factory legislation, and he emphasized the constructive and co-operative aspect of the work of the factory inspectorate There are now 409 inspectors, and it is hoped to have 445 very soon , but quality and experience are regarded as more important than numbers Other innovations in the Bill, which received the Royal Assent on July 29, empower the Minister to make special regulations as to the measures to be taken in factories to reduce the risk of fire, including regulations prescribing requirements as to the internal construction of a factory and the materials to be used, and call for the provision and maintenance in every factory of appropriate and readily available means for fighting fire.

In the debate, Lord Wilmot of Selmeston remarked that the Bill is an outstanding example of Parliament at its best in the active co-operation of Government and Opposition in pursuit of a common aim Lord Stonham expressed the hope that in promoting a partnership of safety in the factories, the Government would greatly strengthen the provisions for consultation and research into safety, and suggestd that full information was a prerequisite of confidence Lord Taylor estimated that sickness and accident in industry in Britain represent a loss of £780–£1,000 million a year, mostly through minor illness and minor accident, and he stressed the importance and value of an efficient industrial health service, including such a co-operative and mobile industrial health service as had been created at Harlow The Earl of Dundee particularly welcomed this suggestion as providing a solution to the problem of making trained assistants available to the smaller type of factory

The Bill obviously strengthens the contribution which science can render to industrial health and safety On the second reading of the Bill in the House of Commons last November, the Minister of Labour and National Service emphasized the critical importance of the strength and efficiency of the factory inspectorate, and this was recognized on all sides Mr Robert Carr, however, directed attention to the way in which the growing complexity of industry has increased the difficulty of progress simply by enforcement It has become more and more impossible for a general inspectorate to possess all the technical qualifications needed to cover the whole range of industry in its area With all the help it can draw from a more or less centralized and specialist branch, to which we must look increasingly for encouragement and advice for major advances in the future, we are once again reminded of the importance of the continual expansion of education and training facilities in Britain

Three other recent debates have also stressed the importance of this factor, and particularly the need to implement the recommendations of the Carr Report on recruitment and training of young workers in industry Intervening in the debate on secondary education in the House of Lords on February 26, Lord Rochester urged that the employment of young people, and particularly their training as apprentices, should be regarded just as much a part of their education as that which they receive at school, and that before steps were taken to raise the school-leaving age further, the possibility of industry absorbing them all at any one time each year, instead of three times as at present, should be examined Lord Rochester thought that to limit intake to one occasion in the year might in practice prove a retrograde step even to the technical education of the boys, but he urged that from the point of employment the problem is much too important to be handled without the closest consultation both with the trade unions and the employers

That aspect was also stressed in a debate on the effects of automation, on a motion of Mr F Lee in the House of Commons on May 1 Mr Lee's motion, recognizing the need for British industry to keep abreast of modern production methods, and also the need to allay fears of heavy unemployment, urged an intensive study of the probable consequences of automation, and that the Government should invite industry to co-operate in introducing the necessary changes with a minimum of hardship to its employees, and in supporting the motion Mr Austen Albu emphasized the bearing of technical education Mr MacLeod, in his reply, referred to the survey which had been made by the Department of Scientific and Industrial Research in 1954, and to the general endorsement of the conclusions of the report in July 1956 by the National Joint Advisory Council A subsequent inquiry by the Board of Trade, the results of which were published in the *Board of Trade Journal* of February 1958, suggested that automation would tend to decrease the number of unskilled labourers but increase the number of skilled technicians of all kinds Firms did not expect automation to lead to any severe reduction in the size of their labour force, partly because that force would be re-deployed substantially within the factory, and partly in consequence of an increased level of activity Mr. MacLeod believes, however, that increase in apprenticeship training is the responsibility of industry, and that the Government can only indirectly stimulate that He referred to the studies of technical change which the Department of Scientific and Industrial Research is already sponsoring and thinks that this work on the social aspects of technological innovation might be better co-ordinated and given more publicity He undertook to raise this question with the National Joint Advisory Council.

In opening a debate on youth employment problems on April 30, Mr. A Robens suggested that the future of Britain is based on the development of our technical skills, and that we must take firm action to ensure that our people are highly skilled and able to make full use of the possibilities offered in electronics, nuclear power and transfer machines. Our educational programme, including the development of technical education, contemplates an output of about 20,000 scientists and technologists a year by 1970, and to make full use of the technologists some five or six technicians are required for each technologist The production of these technicians and craftsmen is regarded by Mr Robens as the key problem, and to meet the needs of the increased number of school-leavers we should be taking about 135,000 into skilled apprenticeship a year. The evidence of recent months, he asserted, is that there are insufficient vacancies for boys who have the necessary educational qualifications, and he believes that only by persuasion or legislation will industry be induced to provide the extra training places required, many of which would be surplus to present requirements He said that the trade unions have a responsibility here —in the printing trade and in the shipbuilding industry the number of apprenticeships is strictly limited.

Mr Robens advocated re-examination of the length of time required for an apprenticeship and challenged the practice of restricting entry to those leaving school at fifteen or sixteen He believes the older boy with added educational qualifications would be likely to acquire his craft skill more rapidly, and further, that full employment could not be guaranteed on the basis of an inevitable job Mr Robens suggested that since industry could not do this on its own, the Ministry of Labour should assist by making use of redundant Royal Ordnance factories or Ministry of Supply factories, so as to meet the needs of the small firms for training apprentices Something more was required than had been recommended by the Carr Committee

The Parliamentary Secretary to the Ministry of Labour and National Service warmly welcomed Mr Robens's speech, though he thought the prospects of employment for boys and girls depend on economic expansion and not merely on the size of the bulge, and he was not convinced that opportunities for apprenticeship are as limited as Mr Robens suggested He believes that the Government's part should be, first, to provide adequate facilities for technical education, and secondly, to shape the conditions in which industry can best play its own part The Industrial Training Council should take a most important part in developing a strong and effective leadership in industry towards expanding training opportunities in each individual industry, and the Council has, in fact, already asked both employers and trade unions to examine urgently the Carr Report The Government also proposes to make a grant of £75,000 to the Council to further the appointment of training development officers, either by the Council itself or by employers' organizations, joint industrial councils or similar bodies He was confident that the Carr Report has already had a profoundly beneficial effect on the situation

Mr Robert Carr, who also spoke, explained that the Carr Committee was influenced in its recommendations by the view that more rapid progress would be achieved by building on practice and tradition rather than by breaking completely with the present system, even if the Committee did not condone the present rigidity of much of it He believes that it is essentially in the smaller and medium-sized firms that an increase in training could take place in the skills we need, and that help with the first year's training of an apprentice is particularly desirable Pre-apprenticeship courses could be developed in technical colleges, but the development of group apprenticeship schemes requires further attention, and small and medium-sized firms could be helped by more block release in technical colleges as an alternative to day release While welcoming Mr Wood's announcement, Mr Carr said he thinks there might be a capital grant towards the establishment of joint training centres and tax remission to firms in respect of the number of their apprentices, and finally he stressed the importance of quality.

Mr A Albu, who pointed out that only between 20 and 30 per cent of school leavers receive any further training at all—and in some occupations only 2–3 per cent receive any serious training for their employment—quoted an estimate that we would need 1,300,000 skilled workers and 450,000 technicians by 1966 To provide these, about 86,000 extra apprenticeships would be needed each year, or nearly three times the present number He suggested a levy, based on the number of skilled workers employed, to enable training workshops to be established in technical colleges, and also that the Industrial Training Council should be reconstituted under an independent chairman, with a specialist and highly qualified staff Stress was laid by Miss Elaine Burton and by Miss Joan Vickers on the importance of the Youth Employment Service, and the need to see that this is properly supported, and that youth employment officers are sufficiently well paid to attract able and really qualified people to such posts

Sir Edward Boyle, who replied on the debate, said that to achieve the objectives laid down in the 1956 White Paper on Technical Education, we must achieve an average increase in the number of part-time day release students of about 40,000 a year Although in 1958 there had been a recession of

17,000 part-time day-releases, the advanced levels in technical colleges are progressing well and the colleges are also diversifying their courses and providing new types of courses for the ordinary craft apprentices and technicians The teaching force of the colleges is increasing and in 1958 reached a record total of 13,500 The technical colleges, however, cannot do their best without the active co-operation of industry, and Sir Edward stressed the need for close and regular contact between the staff at the technical college and the training officers and apprentice supervisors in the factory

It is against the background of these debates that the report of the Ministry of Education for 1958* is appropriately considered, particularly the important chapter which reviews developments in technical education since the War, and more especially progress since the White Paper on Technical Education was issued in 1956 Some further information bringing the report more up to date was given in speeches of Lord Hailsham in the House of Lords debate on February 26 and in that of Sir Edward Boyle in the House of Commons on April 27 Sir Edward Boyle pointed out that during the past four years the number of pupils per full-time teacher in primary schools has declined from 32 1 to 30 6, while the number of pupils per full-time teacher in secondary classes has only risen from 20 9 to 21 4 in spite of the movement of the bulge from primary into the secondary schools From now onwards, apart from the year of intermission in 1962, the increase in the teacher force should more than match the increase in school population, and Sir Edward Boyle anticipated that primary classes of more than forty children should be virtually eliminated by the middle 1960's, with no deterioration in staffing standards in secondary schools

From 1959 Sir Edward thinks that an annual net increase of 6,000 teachers can be assumed, as 16,000 students should complete teacher training courses in 1959 and 17,000 in 1960, and this output should be maintained, an increased number of graduates is also expected to enter the schools, and wastage is unlikely to increase More recently, on June 26, Mr Geoffrey Lloyd, the Minister of Education, said that in addition to the programme for 12,000 places announced last September, he has authorized forthwith a programme of 4,000 training college places which should be effective by 1964 Sir Edward Boyle also said that the selection of highly qualified entrants who could complete a course in two years instead of three was being considered

"Education in 1958" records that although in January 1958 there were nearly 6,840,000 children in maintained and assisted schools, the rate of increase has fallen by nearly half, the rise in the number of children older than fifteen was more than double that for the previous year Nevertheless, the percentage of senior children in over-size classes remained the same although the number of over-size senior classes was slightly larger in January 1958 The total number of students taking advanced courses at technical colleges has increased from 9,500 at the time of the White Paper to more than 11,000, and of these nearly 6,500 are enrolled in sandwich courses, compared with about 2,300 early in 1956 During 1958–59, more than 19,600 out of 23,000 students admitted to universities in England and Wales, excluding those from overseas, were receiving awards from public funds, compared with 14,000 during 1954–55

Apart from the firm expression of the Government's conviction that anything like a uniform pattern of secondary education throughout Britain would be wrong, and that instead wide experiment and flexibility in organization should be encouraged, the two chapters on further education are those of most direct interest to the scientist and technologist The first of these provides a convenient concise summary of the progress that has been achieved in technical education during the past five years, without, however distinguishing as clearly as had been done in some recent debates in Parliament between the technician and the technologist One encouraging feature is the decreasing proportion of part-time education at the advanced level In the mid-1950's, more than three-quarters of technical college students who obtained professional qualifications did so by part-time study only By the late 1960's about one-half of those qualifying each year as scientists and engineers will probably have come from a technical college and less than one-third of these will have taken part-time courses

The review refers to the shedding by the colleges of advanced technology of the less advanced work, and there is some discussion of the problem of broadening a technological course It is recognized that a concept of teaching is needed in which the mere imparting of information is replaced by a more active kindling of the student's mind and interest through the personal help and guidance of the teacher, and it is the Government's policy that the colleges of advanced technology should be staffed on a basis generous enough to enable them to provide a tutorial system throughout a diploma of technology course Apart from the great benefit to the students, this should encourage the staff to adopt teaching methods which will increasingly encourage students to work on their own and to think for themselves Of the £70 million authorized for investment in technical college building in Britain during the quinquennium ending in 1961, the colleges of advanced technology claimed about £10 million Encouraging progress is recorded in regional co-ordination at the advanced level, in co-operation between the colleges and industry and in the development of research and postgraduate studies, and to a lesser extent in the development of courses in management studies The need for residential accommodation, however, will only partly be met by the 3,000 places to be provided under the five-year programme, of which nearly 2,000 will be at the colleges of advanced technology, including about 1,000 at the entirely residential college at Loughborough Recruitment of suitable teaching staff for advanced scientific and technical courses is likely to remain a serious and urgent problem, and related to this are the conditions of service for such staff Here the improvement in the climate of opinion about advanced technological education could well be a decisive factor

---

* Education in 1958 Being the Report of the Ministry of Education and Statistics for England and Wales Pp v+261 (Cmnd 777) (London H M Stationery Office, 1959) 12s net

The report stresses the distinctive functions of the colleges of advanced technology and of the universities and rightly urges that both are needed. It would be more reassuring, however, to see the distinctive functions of the technical colleges and of the colleges of technology clearly recognized, and the need to keep the supply of technicians and craftsmen in balance with the expansion in numbers of both technologists and scientists This could well prove a major weakness, and although the apprenticeship system receives notice in the report, the Carr Report is merely noted and its implications even for technical education are not discussed Lord Hailsham's speech in the House of Lords on February 26 was limited essentially to secondary education, and although he referred to the improvement of facilities for teaching science, he did not touch on this vital aspect Between 1947 and 1957 the number of advanced level passes in the General Certificate of Education rose from 10,000 to 14,000 in mathematics, from 8,000 to 15,000 in physics, and from 7,000 to 13,000 in chemistry , and since the War more than £20 million has been spent on the provision and equipment of science laboratories at new and enlarged maintained secondary schools of all kinds and £3 million has been spent in three years on independent and direct-grant schools by the Industrial Fund for the Advancement of Scientific Education in Schools

This report from the Ministry of Education, and the debates in Parliament referred to earlier, demonstrate that the Government is aware of the many problems involved in expanding technical and technological education in Britain , it is the duty of professional associations and similar bodies to impress on those concerned the importance of striking a true balance between the diverse interests involved

CONCEPTUAL FOUNDATIONS OF SCIENCE

Patterns of Discovery

An Inquiry into the Conceptual Foundations of Science By Prof Norwood Russell Hanson Pp ix+241 (Cambridge At the University Press, 1958) 30*s* net

THE general thesis of this book is that observational data become significant only when seen against a given conceptual background or *Gestalt* (p 90) The theme is worked out at various levels Thus Chapter 1 discusses interpretative activity of plain observers , Chapter 2 illustrates, through a historical discussion of the work of Galileo, Descartes and Beeckman on the problem of free fall, the influence of purely geometrical as against physical attitudes on the direction of research , and Chapter 4 emphasizes the importance of physical (as compared with purely mathematical) preconceptions in their hold on Kepler's astronomical thinking Comparatively, these are historical issues, though Prof Hanson here sometimes flirts with something more important, as when he writes that "conceiving of an hypothesis has a logic" and is not merely a matter of intuition or hunches (p 71) Of course it is not But as to "logic" , when we inquire further we are after all given no more than the tame if correct remark that the physicist's task is to find the simplest formula which will include all the known data (p 84)

Hanson's conceptualist thesis is indeed mostly intended to throw light on a number of traditional philosophical issues such as the nature of causal relations (Chapter 3 causes being interpreted as "theory-loaded" (p 54) entities) , the logical status of the laws of classical dynamics (Chapter 5 whether they are considered as definitions or as conventions or as empirically testable statements depends on "the organisation of concepts" (p 96)) , as also the question whether the Indeterminacy Principle states "merely a technical" or rather "a conceptual impossibility" (p 136 , Chapter 6) This last question, perhaps the most interesting in the light of recent discussions on the ideas of Bohm and others, does not receive much clarification, being discussed merely as a further illustration of a philosophical thesis

Altogether, though this book abounds in a wealth of illustrative studies, remarks and quotations, at the end one is left with the feeling of a somewhat hazy and impressionist picture There is a great deal of trailing of the coat , the *bête noire* being "the philosophers", who now fail to grasp the elementary facts of physical reasoning (p 88) , now "think physicists confused" about the use of law-statements (p 109) , and who are finally told that not they but men like Kepler, Galileo, Newton, Einstein and others have developed physics (p 113) Sneering was never a good substitute for argument , it is never certain who these philosophers are that so dismally misunderstand , and on the few occasions when they are named, their arguments are peculiarly misrepresented Thus some contemporary logicians are chastized for having represented physical theory either as an inductive generalization, or as a piece of pure deduction, or, again, as inverse deduction, namely, the postulation (the "thinking up") of hypotheses accounting for the facts (pp 86 ff) Armed with this logical terminology, Prof Hanson imputes to the logician the absurd doctrine that the physicist first thinks up hypotheses at random and then sees what he may perchance deduce from them (pp 71 ff) Surely it was perfectly obvious that what the logician meant was think up hypotheses in the light of the problems they are meant to solve

Disentangling the puzzles and paradoxes of the language of science is a delicate operation , the statements that emerge after due reflexion, when honestly put, are deserving perhaps of slightly more respect than a hasty misreading of the evidence might suggest Prof Hanson writes that "because of the inadequacy of philosophical discussions" of the topics dealt with in his book, he proposes to use physical theory and theorizing as "the lens through which these problems will be viewed" (p 2) One reader at least has certainly gained the impression that the method is, on the contrary, the perfectly standard one of running a definite philosophical line.

But no greater damage could be done to genuine philosophy of science than to suggest that there is an easy way to a solution of its problems , let alone that they may be settled by simply inspecting the metaphysics and the language of science

The book seems most stimulating in its discussion of some of the case-studies referred to, even though one might have wanted some explanations on occasion which would have made the matter less mystifying to the general reader (Who of these understands the theory of the hodograph ? (p 106)) It can certainly be warmly recommended as accompanying reading to more sustained studies in the subject

GERD BUCHDAHL

THE WEEVILS OF FRANCE

Faune de France, Vol. 62

Coléoptères Curculionides (Troisième Partie) Par Adolphe Hoffmann Pp ii+1209–1840 (642 figures) (Paris Editions Paul Lechevalier, 1958) n p

It is now more than forty years since the last comprehensive work on European beetles appeared The present volume in this well-known series deals with the remaining weevils occurring, or likely to occur, in France and Corsica It is issued, unusually, in a stout and durable cloth binding Keys to all groups, including sometimes the varieties of a single species, are given Each couplet usually contains several easily observed characters and the keys appear to be reliable There is a full description of each species, together with many references

The figures are even more numerous than in the earlier parts, averaging more than one per page They exhibit a variety of styles and techniques but seldom reach the standard one expects nowadays in a work of this kind Some of the figures of antennae and tarsi are particularly crude , stippling and shading are frequently used where a simple line drawing would be far more effective

The author's system of classification is rather individual and open to criticism Following Reitter (1912) he has included some twenty or so subfamilies as tribes under the name "Calandrinae" Also the Attelabidae are denied their full family rank , *Rhynchites* was even used as an example of the Phanerognathi in the introduction (Part 1) In addition a number of long-established generic names (for example, *Dorytomus*) have been sunk, though in such cases an explanation is given and the reader can form his own opinion with the aid of the references The fact that the general classification of weevils has not been studied since 1866 and that the new Code of Zoological Nomenclature has yet to appear in print reduces the weight of these criticisms Furthermore, this work is essentially a faunistic study, not primarily intended to make a fundamental contribution to anatomy or taxonomy

It is in its faunistic aspect that the value of this work lies The author has taken the greatest pains to record accurately and often in great detail both the distribution and the biology of every species as far as these are known Again many references are given Many galls, etc , and leaf-rolling techniques are illustrated

Following the main body of the text is a lengthy list of additions and corrections to the whole work, also a list of food-plants with their associated weevils and a general index

R T THOMPSON

THE INVERTEBRATES

The Invertebrates Vol 5

Smaller Coelomate Groups—Chaetognatha, Hemichordata, Pogonophora, Phoronida, Ectoprocta, Brachipoda, Sipunculida, The Coelomate Bilateria By Libbie Henrietta Hyman (McGraw-Hill Publications in the Zoological Sciences) Pp viii+783 (London McGraw-Hill Publishing Company, Ltd , 1959) 104*s* 6*d*

The fifth volume of Dr Hyman's series on animal phyla is devoted to the smaller cœlomate groups, except the Echiurida These she divides into three sections the enterocœlous cœlomates or Deuterostomia (Chaetognatha, Hemichordata and Pogonophora), the lophophorate cœlomates (Phoronida, Ectoprocta and Brachiopoda) and the protostomatous cœlomates (Sipunculida) It must have been a difficult task mastering the literature on such widely varied forms of life , the bibliography is excellent

Each chapter is arranged on the same lines as those in previous volumes—history, general characters, classification, morphology, embryology, ecology and physiology, geographical distribution and relationships, so that it is easy to find a particular section. The illustrations are good on the whole, mostly copied from original papers, but a few have deteriorated in reproduction, such as *Bathyspadella*, Fig 15*A*, and the nervous system of phoronids, Fig 87. Lettering by numbers enables the reader to test his knowledge, and this is applied uniformly throughout the book

Some phyla have been exhaustively dealt with elsewhere, such as the Hemichordata, by van der Horst , others are little known or have not been adequately treated in available books and monographs It is to the latter groups that the zoologist will gratefully turn first Here for the first time we have a clear account, largely translated from the Russian, of the new phylum Pogonophora, the beard bearers, deep-sea worm-like creatures with a heart and vascular system but no digestive canal The dredging of twenty-two species of pogonophores, chiefly from the Behring and Okhotsk seas and from the Skagerrak off Norway, is one of the most remarkable finds in modern zoological research, comparable with the discovery of *Latimeria* and *Neopilina*

More than a third of the volume is devoted to the Ectoprocta, a group which "is burdened with a large and fantastic terminology" Dr Hyman therefore has correlated the terms used for the parts of the colony with those employed in invertebrates generally For her study of the Ectoprocta she travelled to Brazil, to consult with Prof E Marcus, who had worked so extensively on that group The result is an excellent account Dr Hyman prefers to call the phylum Ectoprocta and to use Bryozoa in a popular sense only, since the latter name included the Entoprocta, which must now be removed from close association with the Ectoprocta

The chapter on Brachiopoda is also a competent piece of work, especially for the palæontologist It is strange that the name is misspelt on the dust cover and the title page

The final chapter, entitled "Retrospect", enables the author to correct a few mistakes in the earlier volumes, to add short accounts of recent work not previously known and to state her views on current trends in zoology The last she does very forcibly :

"Hemichordata *must* be removed from Chordata and made an independent phylum of invertebrates"; "The concept Gephyrea must be obliterated from zoology"; "Ctenophora are a sharply delimited group with definite characteristics that entitle them to separate phyletic rank. It is even not at all settled that they have originated from Cnidaria"; "The Entoprocta are maintained as a phylum distinct from the Ectoprocta".

The volume reaches the high standard of all McGraw-Hill publications. Its cost in Britain is certainly very high, but its value as a compilation of up-to-date knowledge is undoubted. All zoologists will wish Dr. Hyman renewed health so that she may complete the great task she has set herself, and will look forward to the next volume, which is to deal with the Mollusca.

N. B. EALES

MODERN THEORY OF THE INTEGRAL

An Introduction to the Theory of Integration

By Prof. Adriaan C. Zaanen. Pp. ix+254. (Amsterdam: North-Holland Publishing Company; New York: Interscience Publishers, Inc., 1958.) 50s.

PROF. ZAANEN'S reason for adding to the considerable number of books surveying the field of modern integration, from the classical Lebesgue theory to the developments of Radon's extension of this theory to abstract spaces, is that such accounts generally rely either on the approach through measure theory or on the concept of the linear functional; he wishes the young analyst to be familiar with both procedures. Thus after a brief preliminary section on set theory, he defines measure over a semi-ring and builds up a more general measure by an extension procedure; then Stone's method of defining the Daniell integral as the extension of a linear functional over the class of step functions is seen to be practically a special case of the extension procedure for measure. The author gives plenty of illustrations, particularly helpful in showing how the older theory fits into the more modern, so that, for example, the extension procedure applied to the Riemann integral yields the Lebesgue integral. Fubini's theorem on the reduction of a multiple integral to repeated integrations is carefully studied, as is the tedious but important Radon-Nikodym theorem, which may be regarded as a very high-level version of the change of variable in an integral. Later chapters give some applications, such as unitary transformations in Hilbert space, and ergodic theory. Measure over a Boolean algebra is excluded, but Carathéodory's book is available; and integration over a locally compact space and the related Haar measure are omitted, since an account of the relevant topology would have substantially increased the size of the volume.

The exposition is clear and precise, provided the reader pays unremitting attention, and provided he does not neglect the exercises, an integral part of the text. "The student who omits them is like the man who, when attending an excellent dinner, wants to race through the main courses only, and (under the misapprehension that it is merely the nourishing value that counts) refuses to touch the wines and little delicacies which are offered him"; and the author is offering Montrachet, not Coca-Cola.

INTERNATIONAL CYTOLOGY

International Review of Cytology, Vol. 7

Edited by Prof. G. H. Bourne and Prof. J. F. Danielli. Pp. x+684. (New York: Academic Press, Inc., 1958.) 16 dollars.

THIS volume, issued under the auspices of the International Society for Cell Biology, is probably the most valuable and interesting of the series, of which it is the seventh. Among the well-known contributors are Don W. Fawcett, Françoise Haguenau, Johannes Rhodin, F. G. Spear and Paul Weiss. The articles by Spear on the biological effects of radiation and by Ilse Lasnitzki on carcinogens, hormones and vitamins in organ cultures are topical in view of widespread interest on the effects of atomic tests, and of cigarette smoking. Spear gives a comprehensive historical review on radiation physics, the general response of living tissues to radiation and radiation chemistry, and has cleared the ground for a new approach to this field. He quotes J. A. V. Butler: "We are at the moment in the position of a man who tries to elucidate the mechanism of a telephone exchange by throwing bricks into it and observing some of the results". Naturally, Spear's section on the possibilities of chemical protection against radiation effects is of considerable interest. A number of chemical and physical agents are claimed to have such protective action in certain cases. He lists cysteine, glutathione, BAL, thiourea, glucose and ethanol. The intimate cytological results of radiation could not be examined more than cursorily by Spear. Many years ago M. J. D. White discovered as a by-product of his work on the effects of X-rays on the maturation phase of locusts that in many cases the single sperm 'middle-piece' became double, triple or even quadruple. Recent work at the Argonne National Laboratory, by Tahmisian's group, working under the auspices of the U.S. Atomic Energy Commission, has shown that the insect 'middle-piece' arises from a number of separate bodies which normally fuse to form the 'neck body'; radiation prevents their fusion, but does not prevent their growth. Further work along these lines with electron microscopy should be fruitful.

Ilse Lasnitzki, using the watch-glass plasma-extract clot technique of Fell and Robison, has investigated the effect of carcinogenic hydrocarbons on human fœtal lung, and mouse prostate, the influence of sex hormones on embryonic development of sex organs, and the changes produced by vitamin A. Lasnitzki provides some remarkable photomicrographs of the effects of 3,4-benzopyrene from cigarette smoke, on the bronchiolar epithelium. Carcinogenic hydrocarbons and sex hormones stimulate cell division in basal cells of skin and vagina, and thus induce abnormally high proliferation.

The section by Françoise Haguenau, a distinguished member of the French School of electron microscopy, goes into the question of ergastoplasm or endoplasmic reticulum. The name ergastoplasm was coined by Garnier (1897, 1899) for the *Nebenkerne* in gland cells. His work was amplified by other members of the Nancy School of Histology, such as Prenant and Bouin. Copies of their figures occur in many of the major works on histology. Happily, Haguenau also mentions the contributions of the Japanese cytologist Sakae Saguchi in this connexion. Electron microscopists entered the field, and by about 1947 really good electron micrographs of gland cells had begun to appear, pioneer work being carried out at the American National Cancer Institute by Dalton *et al.*, and at the French Cancer Institute at Villejuif by Oberling's group. The way was then open for the excellent high-resolution studies by the Swedish workers under Sjostrand, and by the active Rockefeller group led by Porter. During this enriching period, a controversy arose on nomenclature as a result of the continued use of Porter's term 'endoplasmic reticulum', which the Americans in particular believed proper to describe the ultrastructure of the classical ergastoplasm discovered by the French. Space allowed to the reviewer does not permit further reference to this topic, but Haguenau remarks, "It has been emphasized that the general acceptance by electron microscopists of the word *ergastoplasm*, in its original context would do much to bring order to the present terminological confusion".

Don W. Fawcett writes on the structure of the mammalian sperm as determined by electron microscopy. Naturally with the higher magnification and excellent resolution of the modern electron microscope, recent authors provided with these blessings have been able to better the often pathetic past efforts of the optical microscopist in this field. Nevertheless the electron micrograph has not produced any new basic facts except possibly for recognition of the peculiar lamellation of the Golgi apparatus—yet Pollister (Vol. 6 of this series) claims that Jan Hirschler did understand that the Golgi apparatus was essentially a lamellated structure. Of great interest to-day in the structure of the metamorphosing spermatid is the neck region. Fawcett holds that the base of the flagellum is connected to the head by a segmented body that is probably a highly modified distal centriole, but the reviewer has yet to see any micrograph of this region which does not show a special neck body, centriole adjunct, archoplasm (Grassé, Carasso and Favard), etc., which is material separate from the proximal centriole. In fact, the electron microscope has shown that the head centriole is not the major attachment area of head and flagellum—there is a separate structure or packing which reaches its highest state of development in insects. There seems to be no recent evidence that the centriole divides more than once in normal spermatogenesis. It must now be admitted that the mammalian post-nuclear body and the neck body or centriole adjunct are different structures.

Paul Weiss discusses cell contact—that is, (1) contact relations between cells and their physical substrata, (2) the mutual reactions of cells on contact with one another and (3) the transmission of specific agents and influences from one cell to another by direct contact. Weiss considers a cell to be in contact with another body not only if the two surfaces are in direct apposition, but also if they are separated by a narrow space occupied by a molecular population the free mobility of which is restrained. In his usual suggestive manner, Weiss has investigated the 'bobbin' structures at cell interfaces of epidermal units, and goes on to discuss the possibility that in cancer cells undergoing metastasis there is a close relation between loss of specific surface contact on one hand and mobilization and proliferation on the other. Mobilized normal cells, after recovering co-aptive relations (for example, epithelia meeting their own kind), cease to proliferate, whereas cancer cells under comparable conditions evidently do not. Weiss omits mention of the paper by Dalton, Kahler and Lloyd (*Anat. Rec.*, 111, 1951).

Papers emanating from Sjostrand's laboratory have been marked by helpful interpretative drawings which can only be made up by close study of many micrographs. These drawings will be used gratefully by authors of histology books. Johannes Rhodin's study on the anatomy of kidney tubules is a good example of Swedish work, the diagram on page 506, Fig. 14, being excellent. The studies on kidney by Pease, Dalton, Rhodin and others can now be followed by experimental work.

Another paper from the Karolinska Institutet is by Hans Engstrom and Jan Wersall. Engstrom is a practitioner in the ear, nose and throat clinic of the University of Gothenburg, yet has managed to collaborate in this erudite study of the structure and innervation of the inner-ear sensory epithelia.

A further paper is by L. M. J. Rinaldini, of the University of Cordoba, Argentina, whose work was carried out at the Strangeways Research Laboratory, Cambridge. No doubt Rinaldini will read Weiss's article with appreciation, as the two valuable papers have certain meeting points. Rinaldini has covered a great deal of difficult ground in an interesting manner, and of all the papers here mentioned, this has needed the widest grasp of the international literature on biochemical and biophysical cytology.

The supposed hypothalamo-neurohypophysial neurosecretion has been carefully considered by J. C. Sloper, of the Charing Cross Medical School, London. The subject of neuro-secretion is one that is largely made up of doubtful histology and worse cytology. Degenerate and effete cells stain darkly in toluidine blue, iron hæmatoxylin, etc.—these are supposed in some cases to be neurosecretory, whereas to the reviewer the most convincing vertebrate nerve cell secretions are those demonstrated by electron microscopy by Palay, Van Breemen, J. D. Green and others. In the case of the sympathetic neurones of the mouse, similar fine 'secretory' bodies exist in animals a few days old, and soon disappear; older cells become packed with formed bodies which are heaped aggregations of effete mitochondria lying mainly at the axon end of the nucleus. Sloper remarks that future investigations will be facilitated by a more exact knowledge of the nature of 'neurosecretory' material, and he feels unable to equate the several categories of inclusions demonstrated by various workers.

The remainder of this volume has papers on the "Lymphocyte", by O. A. Trowell of the Radiobiological Unit at Harwell, on "Autoradiographic Studies with S^{35}-Sulphate", by D. D. Dziewiatkowski, of the Rockefeller Institute, on "Recent Advances in the Study of the Kinetochore" (centromere), by A. Lima-de-Faria, of the Institute of Genetics of the University of Lund, and finally on "Lamellibranch Muscle" by J. Bowden, of the Anatomy Department of the Queen's University, Belfast. These valuable studies are all of the highest standard, and it is regrettable that they cannot be reviewed here at length.

Looking back on the various volumes of this series, which have appeared under the guidance of Bourne and Danielli, one is impressed with the fact that the problems encountered in the study of the living cell nowadays seem to become more complex and more insoluble. It would be pretentious for us to think otherwise. J. BRONTE GATENBY

A Defence of Free Learning

By Lord Beveridge Pp xiv+146 (London Oxford University Press, 1959) 18*s* net.

IN this book Lord Beveridge has drawn in the main on the documents collected for their work by the Academic Assistance Council and the Society for the Protection of Science and Learning to give a sober but moving narrative of twenty-five years work in Britain to help university teachers and scholars driven from their work on political or racial grounds It is not a philosophical or theoretical argument for academic freedom but a factual account of what has been done in Britain alone, beginning with the expulsions from Germany initiated by Hitler in 1933 and continuing down to the problems presented by the intolerance persisting after the Second World War, including the Hungarian persecution of 1956-57 It is a story little known outside the universities and is told without embellishment, save, perhaps, where in his concluding chapter "The Folly of Tyrants", Lord Beveridge, summarizing, points to the rich harvest which Britain has reaped by her reception of these refugees There are indeed some dark places in the story and Lord Beveridge does not attempt to conceal them On the other hand, he does not overstress them and points out fairly enough that, even in the darkest hour of 1940, there were always those in Britain ready to protest vigorously against administrative error or tardiness and to insist on the revocation of stupid decisions Five debates in the House of Commons in less than eight months of desperate war testify to a sense of justice and a vigilance of which Britain has a right to be proud The most moving chapter is, perhaps, that entitled "Wandering Scholars", in which Lord Beveridge sets forth some of the typical experiences of these scholars collected from their replies to an inquiry sent out in June 1958 No eloquence could make the human issues plainer, nor is more needed by way of argument to demonstrate that here is a continuing problem calling for forethought and imagination, as well as practical help if its difficulties are to be resolved and some of the existing gaps, notably in relation to professional work, are to be closed

In writing this book, Lord Beveridge has added to the debt which Britain as well as wandering scholars owe him and his colleagues, first on the Academic Assistance Council and then in the Society for the Protection of Science and Learning

R BRIGHTMAN

Systematic Mineralogy of Uranium and Thorium

(Bulletin 1064, U S Geological Survey) By Clifford Frondel Pp viii+400 (Washington · U S Govt Printing Office, 1958) 1 50 dollars

FOR the past ten years an intensive investigation into the mineralogy of uranium and thorium, undertaken in connexion with economic studies of radioactive ore supplies, has been in progress in the laboratories of the U S Geological Survey, the U S National Museum, and the Mineralogical Department of Harvard University The vast amount of new information forthcoming from these researches has now been assembled by Prof Frondel of Harvard, in a monograph which is quite the most outstanding work among the half-dozen or more major text-books on radioactive mineralogy that have appeared in the U S S R , North America and France during the past two years Each of close on a hundred mineral species is very fully described according to its synonymy, composition, crystallography and crystal habit, physical and optical properties (with X-ray powder diffraction interplanar spacings), synthesis, criteria for identification, mode of formation, and natural occurrence Comprehensive determinative tables are given in an appendix and there is a bibliography of 800 items Although the work has been three years in the press and thus gives no account of the most recent discoveries, no earlier book in this field has achieved anything like the same coverage and certainly none can parallel this inexpensive Bulletin in accuracy of data and freedom from misprints Most of the opaque multiple-oxide minerals of uranium, other than species of economic importance such as brannerite, davidite, and the pyrochlore-microlite series, have still to be studied in detail , for the rest, the many geologists and mineralogists now concerned with uranium ores will unhesitatingly accept this monograph as their foremost authority.

C F DAVIDSON

Numerical Analysis and Partial Differential Equations

By George E Forsythe and Paul C Rosenbloom (Surveys in Applied Mathematics, Vol 5) Pp x+204 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd , 1958) 60*s* net

THIS survey contains two unrelated essays In the shorter of the two, Forsythe summarizes recent work in numerical analysis, with special references to developments in the U S S R There is an account of the chief Russian automatic computers, details of which have been available only in the past two or three years Forsythe also stresses the skill with which Russian workers have brought to the service of numerical analysis some of the most up-to-date tools of pure mathematics, such as constructive function theory and functional analysis The bibliography is helpfully selective rather than blindly comprehensive, and the author's comments on the various items are crisp and efficient

Rosenbloom's essay does not attempt to describe all recent contributions to the study of partial differential equations, but it gives a valuable indication of the way in which the theory of function spaces and the transform calculus have yielded fresh results about elliptic and parabotic equations. The young research worker should find this a helpful guide to some of the main lines of advance ; the bibliography, of some 700 items, may well frighten the novice, and some further annotation would have been an advantage.

T A A BROADBENT

Clinical Biochemical Method.

By Dr A L Tárnoky Pp x+239 (London Hilger and Watts, Ltd , 1958) 50*s* net

MOST large clinical biochemistry laboratories have their own particular methods for routine examinations, or more likely use modified classical ones in the light of their experience Dr A L Tárnoky's book describes the methods used routinely in his laboratory at the Royal Berkshire Hospital It is a straightforward bench manual giving most of the usual tests arranged in alphabetical order Each test is described under the headings of principle, specimen required, method, result, normal value, reagents required and remarks There is a small but valuable appendix which gives procedures for checking analyses in a laboratory, lists of books and references and a list of manufacturers There are only a few diagrams , for the class of worker who would most depend on this book, spectroscopic charts and illustrations of electrophoretic patterns, for example, would have been of great value Again, the omission of any mention of paper chromatography or of serum transaminase tests is noticeable On the other hand, the directness and simplicity of the text are much to be commended

This book will be very useful to technicians, clinical pathologists and doctors in smaller hospitals in Britain and overseas, and to medical research workers who need to do routine clinical biochemical tests as part of a larger research scheme It forms a useful addition to the larger and more well-known text-books of clinical biochemistry

Biological Laboratory Data

By Dr L J Hale (Methuen's Monographs on Biological Subjects) Pp x+132 (London Methuen and Co , Ltd , New York John Wiley and Sons, Inc , 1958) 15*s* net

BOOKS intended as laboratory aids are by no means rarities and cover a great variety of subjects, while they range in their appeal from the beginner to the advanced research worker This book falls rather into the latter category and it has some unusual features which single it out among those devoted to the biological sciences The emphasis on the mathematical side, for example, is conspicuous Out of a total of one hundred and twenty-seven pages, twenty-three deal with mathematical data, twelve are devoted to statistical data and formulæ and thirty-five to physical and chemical data This is not an overweening proportion but it is more extensive than in most books of this size and type and the material is very handily presented

The result, however, has been somewhat to repress the more strictly biological matter, so that cultural methods for the laboratory get only seven pages, inclusive of a page of references to other works, while histological and histo-chemical data cover only fourteen pages This seems meagre considering the enormous amount of such data available and a better balance might easily be achieved There is no doubt, however, of the value of the material which the book contains and the mathematical sections alone should ensure it a wide popularity among biologists, who so often feel the need of guidance in that field

R C McLean

The Salmon

By Dr J W Jones (New Naturalist Special Volume) Pp xvi+192+12 plates (London William Collins, Sons and Co , Ltd , 1959) 18*s* net

ON the whole Dr Jones has written a readable book The chapters dealing with the spawning of adult salmon and young males are the best in the book, as it is there that Dr Jones has drawn largely from his own work and experiences An important chapter is devoted to scale reading from which many of the details of the life-history of the salmon have been discovered

The chapter on "Salmon in the Sea" is frankly disappointing, as sufficient use has not been made of the information amassed in the past thirty years, so the reader does not get a clear picture of the long migrations which salmon often make when returning to the river of their birth

Other chapters deal with the early life of the salmon, the return to the river, the return to the sea and the salmon river The book is completed by four useful appendixes dealing with the characters of salmon and trout and their hybrids, a key to the genera of the Salmonidae, etc , a description of the parasites of salmon and methods of estimating lengths from scales Serious readers will also find the bibliography of value in their more extensive reading

One serious criticism of the book I have to make is that many of the illustrations are poor The publishers inform us in a note opposite the title page that in this series of publications "the animals and plants are described in relation to their homes and habitats with the *help of fine photographs*", the italics are mine Plates 4, 5, 6 and 7 are certainly not based on fine photographs as I have often seen better in angling magazines

Arthur E J Went

Nitration of Hydrocarbons and other Organic Compounds

By A V Topchiev Translated from the Russian by Catherine Matthews Pp vi+329 (London and New York Pergamon Press, 1959) 90*s* net

TRANSLATIONS of foreign texts are seldom successful unless carried out by workers in the same field with freedom to incorporate recent material The pitfalls are well illustrated by this book, which is both out of date and unreadable There are one or two references to papers published early in 1954, but none to the more recent literature Since much work of fundamental importance to this field has been published during the past five years the book is of little value as an account of the subject, although it does contain a rather complete account of the earlier literature and a useful summary of Russian papers that are not readily accessible in Britain

It is most unfortunate that the distinguished author of the book could not have been persuaded to revise it during translation

M J S Dewar

Commonwealth Universities Yearbook, 1959

Pp xxvii+1407 (London Association of Universities of the British Commonwealth, 1959) 84*s* , 13 dollars

THE invaluable "Commonwealth Universities Yearbook" is now in its thirty-sixth edition There are no major changes from last year's edition, when the new enlarged format was introduced, but the size has increased from 1365 to 1435 pages, mainly in order to accommodate expansions in university staff

The University of Sherbrooke in Canada and Sardar Vallabhbhai Vidyapeeth in India are mentioned for the first time, and the University College of Fort Hare in South Africa now has a complete entry Two events which occurred in Australia as the book was going to press are also mentioned briefly the founding of Monash University in Victoria and the transformation of the New South Wales University of Technology into a multi-faculty University of New South Wales

The valuable essays in higher education in the various countries have been brought up to date, and where necessary additions have been made to the maps showing where the universities are located

New features of this edition include a full-length summary of admission requirements by the Canadian Universities, and information on the transfer courses at certain British universities whereby students who have previously studied arts subjects can switch to science

BEHAVIOUR IN CONVENTIONAL AND EXTRA-TERRESTRIAL FLIGHT

SOME FUTURE ASPECTS OF AVIATION MEDICINE

By AIR COMMODORE W. K. STEWART, C.B.E., A.F.C.

Royal Air Force Consultant in Aviation Physiology, Institute of Aviation Medicine,
Royal Air Force, Farnborough

AVIATION medicine is the normal clinical practice of medicine as applied to the special circumstances of flight; but in this survey it refers to the basic sciences of physiology, psychology and biochemistry.

The growth of aviation medicine has been largely due to preceding advances in combustion, aerodynamics and metallurgy; in turn, these advances were the result of operational plans, either civil or military. At the present time, most aircraft or missiles appear to have a cycle of approximately ten years for the stages of planning, development and production, and it is reasonable to assume that some such cycle will be entailed in the future. Past experience in the conduct of biological research has indicated that such a period should be sufficient for the production of the major contributions from aviation medicine. It is also sufficient for the design and installation of the capital equipment required, both for fundamental and applied work.

It has become clear, however, that a significant contribution to a particular phase of the programme will depend on adequately trained staff. No institute or laboratory of aviation medicine will survive in the future if it lacks staff of the proper orientation in the relevant biological disciplines.

Since these are likely to be of a complex kind, skilled research workers will be correspondingly few in number. It is held, therefore, that it is necessary to plan future activities in aviation medicine so as to ensure the early derivation of biological information.

Survey of Some Future Problems

For the purpose of this review, it will be assumed that manned aircraft will continue to be used in an era of unmanned ballistic missiles, or vehicles, and later in an era of orbital-manned vehicles. Such aircraft may be hypersonic, may operate at low altitudes, or in the outermost layers of the atmosphere, for short or very long durations. They will subject their occupants to stresses and environmental changes, different in degree, but on the whole basically similar to those of contemporary aircraft, and this, to some extent, may be also true for orbital-manned vehicles.

The experience gained in the past fifteen years in applied physiology and psychology is sufficiently extensive to encourage the belief that problems arising in these disciplines can be successfully solved, since the techniques involved and equipment necessary can be foreseen to a considerable extent.

For extra-terrestrial flight, many of the problems, weightlessness, for example, can only be solved either by extrapolation from poorly quantified data, or by direct experience.

Hazards such as the effects of corpuscular radiations and cosmic rays will almost certainly be a more worthwhile sphere for laboratories of physics than for an institute of aviation medicine. In considering the philosophy of extra-terrestrial flight, it is always difficult to justify biological participation since apart from the remote possibility of acquiring data of importance to microbiology, it is unlikely that purely physiological studies will advance general knowledge in proportion to the cost of the venture.

The proper function of biological researches is undoubtedly to further manned exploration of the upper atmosphere or beyond, and even here it is wise to hesitate in considering, not whether this is feasible, but whether it can ever lead to more than an *ad hoc* determination of the ultimate limits of man's endurance.

However, the value of manning a satellite may ultimately depend on those functions of the central nervous system which are difficult to simulate, either in absolute terms or in size and weight. It is probable that what a man can be expected to do in a satellite could only be determined by actual experience; but it is unfortunate that the environmental conditions which he will encounter are those most likely to affect the logical and purposive functioning of the brain.

The problem here is that the behaviour of animals and man is still very far from being understood; aberrations of behaviour in flight are still more difficult to investigate, and if any occur in the occupant of a satellite the determination of their basis might be quite impossible. Clearly, advancement of such knowledge would be of benefit, not only to those nations with official programmes of the 'man in space', but also to aviation in general, and would constitute a field in which expenditure of effort and money would be justified.

Every practitioner of aviation medicine has some acquaintance with cases of abnormal behaviour in flight. For many of these cases, no simple answer can be given, although they are commonly referred to as 'manifestations of disorientation', but analysis of near accidents has shown a higher frequency than suspected of misinterpretation of visual information and illusions of different kinds.

Some of these illusions were hypnagogic in nature; others led to panic or startle reactions. Some were obviously associated with reduction in sensory input and probably an element of perceptual conflict. In future manned flight, there will be an increased exposure to the factors probably initiating such changes in behaviour It has therefore become mandatory to review their relationship to physiological mechanisms, and to try to determine the primary stimuli for chains of reaction Do disorders in behaviour determine physiological events, or is it necessary to postulate underlying abnormalities in the neuro-physiological or homœostatic spheres ? Probably both mechanisms are implicated at different times

The classical problems of behaviour in flight, such as fear and fatigue, are entirely material to this argument Hence it is essential to derive such advances in knowledge that adequate theories can be constructed, adequate in the sense that they can produce methods of prediction of alterations in learned behaviour under stress, whether this stress be neurogenic or systemic in origin The purpose of this review is to indicate some avenues of research which could be explored and which might prove of value, not only in conventional aviation medicine, but also in what is rather loosely termed 'space medicine'

Survey of Brain Mechanisms

It is impossible to prophesy how far theories of integration of nervous action will have advanced in the era of the hypersonic aircraft and manned missiles, and it is therefore probably legitimate to commence with Hebb's[1] ideas concerning the conceptual nervous system He related the function of the brain-stem, or arousal system of Moruzzi and Magoun[2], to the level of the 'cue' function in learning For general reviews of the physiological and psychological aspects those of Jasper, Gloor and Milner[3] or Duffy[4] should be consulted

Stress It is proposed to regard stress from the point of view of Fortier[5] and Fortier *et al* [6], namely, that there are basically two types of stress—neurogenic, initiated through perceptual processes, and systemic, initiated through chemical and metabolic processes In both, the hypothalamus appears to influence anterior pituitary secretion via the hypophyseal portal vessels Permanent interruption of these vessels lowers the normal rate of secretion of adrenocorticotrophic hormone, abolishes reflex secretion of adrenaline in response to stress and also that of the gonadotrophic and thyrotrophic hormones There are indications that the tasks of flight can be regarded in these terms as a stressful occupation, with enhancement of the secretion of adrenaline and noradrenaline, of the output of 11- and 17-ketosteroids, or uro-pepsinogen accompanied by alteration in gastric function

It has not, however, been possible to state that the degree of stress represented by biochemical findings is of unusual severity or to relate them to the degree of fatigue experienced The fact that aircrew trainees hyperventilate more or excrete more ketosteroids than their instructors may merely represent higher levels of arousal than higher intrinsic levels of stress If stress and arousal be synonymous, then it may be necessary to postulate that certain forms of learning set represent stress also Unfortunately it is impossible to investigate the immediate physiological reactions of man exposed to an overwhelming event such as a major loss of control in the air

Further, the physiological parameters which had been investigated in the intact man are second- or even third-order variables , but this does not deny the importance of techniques, such as those of Malmo and his associates[7] It would seem to be important to extend their approach possibly by applying techniques, such as Merton's[8], in order to derive more fundamental knowledge of how anxiety may alter reflexive physiology

If a given level of arousal be equated with stress, then a reduced sensory environment should also, from some points of view, be regarded as stressful In future aircraft or vehicles, in which such factors may well operate, and may be enhanced by fatigue, there will also be the interposition of alterations in environmental and temporal rhythms Both these states may be found in nuclear-powered aircraft as well as satellite or orbital vehicles, and some understanding of their inter-relationship is certainly necessary The approach of Lewis and Lobban[9] into biochemical aspects of alterations in environmental time should be combined with that of Bexton, Heron and Scott[10] into the intellectual effects of perceptual isolation

Behaviour during stress In the future it will be important to ensure that memory and learning will remain as stable as possible during acute stress occurring in a crucial period of a sortie

Tyhurst's[11] study of behaviour in disaster situations on the ground is especially significant in that 75 per cent of individuals affected showed definite impairment of decision-taking, and it is likely that in any normal population of aircrew there must be a significant proportion of men who would evince similar reactions Even if the motivation and training are different, it would be desirable for their safety to select crews in which the 'cue' function alters as little as possible with high levels of arousal In order to do this, much more knowledge will have to be acquired by neurophysiologists

Vogt[12] has pointed out that not only are the hypothalamus and the reticular activation systems of the brain-stem particularly rich in sympathin content but also that loss of this content is accompanied by an increase in secretion from the adrenal medulla It may also be significant that the non-specific thalamic nuclei contain more than three times as much sympathin as the specific thalamic nuclei, since Mahut[13] has demonstrated that electrical stimulation of the non-specific intralaminar nuclei can produce learning deficits in rats provided that stimulation occurs within a given period of the activation of the cell-assemblies concerned

Activity in the arousal system does not stop abruptly following a sensory stimulus, probably because of release of adrenaline Rothballer[14] has determined that the system is likely to be composed of adrenaline-sensitive elements which give an immediate arousal effect upon the electroencephalograph, and other adrenergic or transmitter elements, which are responsible for the long-lasting effects In any stressful situation such as flight, the level of arousal is probably at an optimum as a result of prolonged training , it is also envisaged that the level of circulating adrenocorticotrophic hormone and the feed-back control of the blood value of adrenocortical hormone are also stabilized at a high normal value What happens to this system when a new situation arises in flight which may have originated from lapses in attention or perceptual conflict ?

It can be postulated that corticofugal impulses along the descending pathways to the arousal system[15] may reduce its noradrenaline content and initiate the reflex discharge of adrenaline from the adrenal medulla , and the new level of circulating adrenaline may affect adversely the stability of the arousal system.

It is important to consider that the neurogenic stimulus must be maximal, and the rate of build-up of disorganization of perception must be sudden. Too often one elicits histories of near-accidents of this type: "I have been teaching jet instrument flying for some time with complete confidence in the right things happening if the right control movements are made; but on this occasion, panic and delusion completely took control of my faculties, and I was unable to think and act as I knew I should." Here is a sudden misapprehension leading to a sudden effector activity and the rapid rate of loss of control in high-performance aircraft only reinforces the "panic and delusion".

Despite the fact that the injection of adrenaline into the lateral ventricles of cats produces behavioural effects similar to light barbiturate anæsthesia[16], and despite the probable existence of neurohumoral loops as postulated by McDermott *et al.*[17], how does the disorganization of integrated behaviour arise?

Milner[18] has further elaborated Hebb's theory in the light of recent advances in neurophysiology, and in particular with introduction of the concept of neural inhibition as an active process. This has been demonstrated in the spinal cord on mono-synaptic reflexes by Eccles and his co-workers[19], both by physiological and pharmacological techniques (Curtis *et al.*[20]) and in the neurones of the motor cortex by Li[21].

Even if it is difficult to extrapolate from observations on single neurones by micro-electrode techniques to the organized behaviour of the whole animal and thence to man, the fact that active inhibition can be demonstrated in neurones is of extreme importance. But does one require to postulate the presence in the central nervous system of substances which appear to have an inhibitory action upon dendritic function[22]?

The maintenance of efficient performance in future tasks will depend to a considerable extent on whether there is impairment of attention or vigilance by either fatigue or stress. Mackworth[23] has demonstrated the importance of vigilance in work tasks, and it may be postulated that in any form of ballistic vehicle there may well be increased lag in perceptual feed-back with an enhanced rate of impairment in vigilance.

This is related to two neurophysiological problems in the mechanism of attention. Where and how does the inhibition of a sensory input occur when a more effective perceptual stimulus is presented? And what is the relationship to habituation?

Sharpless and Jasper[24] have already shown that habituation occurs readily in the arousal system when a tone is presented repetitively, but that re-arousal occurs when the frequency of the tone is altered. This is a situation well known to aircrew, who may first gain cognizance of an impending emergency from aberrant noise in the engine.

In the conscious animal, neurophysiological techniques such as indwelling micro-electrodes are of the greatest importance to the elucidation of these problems, particularly when the experimental orientation includes psychological constructs. There are also indications that neuropharmacology may well be implicated.

Hebb[25] has summarized the data on the function of acetylcholine in the central nervous system by stating the situations or cell-masses to which it appears to be limited. There may be significant contributions to theory if there were any relationship between the rich content of acetylcholine in the caudate nucleus and the selective impairment of the delayed alternation response in the monkey produced by stimulation[26]. Acetylcholine, as well as adrenaline, has a direct action upon the neurones of the reticular system[27], and both drugs have no direct effect upon specific sensory projection systems. The use of micro-injection techniques might elicit much data which may elucidate the physiology of the central of sensory inflow. Dawson[28] has reviewed the evidence for the existence of mechanisms of this nature which suggests that there might be a continual control on afferent sensory transmission from centres in the cortex, brain-stem or cerebellum.

Since attention is a much more subtle process than can be accounted for by the arousal system, a controlled sensory block is of great interest and may be the basis for the direction of perception or the selective use of cues. However, arousal does tend to depress evoked cortical potentials in an 'unattended' sensory modality and an element of behavioural alarm may be essential for some of the inhibitory changes which accompany shifting of attention[29].

Neurophysiological studies of such changes should further the establishment of psychological theories of attention.

Inter-Disciplinary Research

If it were possible to measure in any individual, values for learning or 'cue' functions, in relation to values of arousal as affected by environmental or emotional processes, then some estimate of the probable stability of an individual's behaviour during exposure to neurogenic stress might be obtained.

A general approach could be adopted initially in which pilots who have experienced certain types of near accident could be compared with pilots who have not had illusions in flight. Some techniques are more appropriate than others; Stennett[30] has shown that an inverted *U* relationship exists between performance-level and level of arousal, using as criteria palmar conductance, electromyographic gradients and the alpha component of the electroencephalograph. It is probable that such techniques would merely give group identification, and the relative placing of any one individual within a group would not be sufficiently accurate for practical purposes.

For more detailed investigation, use could be made of flight simulators of modern type situated in a reduced sensory environment. The aim would be to repeat in some degree the observations of the Cambridge Cockpit Group, and when fatigue had resulted in lapses of attention, or decrease in vigilance[31], to introduce a perceptual conflict in orientation. Not only would such methodology require development, but also physiological variables should be recorded which show less temporal independence than the electroencephalograph and palmar conductance.

In order to investigate the effects of neurogenic stress upon man, methods of inducing fear or anxiety are obviously required, other than the usual ones of incentives or pain[32]. Again, use can be made of isolation, by immersion in water[33]. If it were possible, for example, to create an illusion of sudden reversion of bodily orientation, data of great interest could be derived from the recording of such variables as electroencephalograph, pulse-rate, respiration electromyograph and muscle blood flow by electronic means.

The correlation of results with anterior pituitary and adrenal activity would be clearly desirable; but it would be essential to employ techniques which would give more direct functional measures than eosinophil counts or urine extractions. Bush and Sandberg[34] have established by chromatography the identity of the major circulating adrenocortical hormone in human plasma as 17-hydroxycorticosterone (compound *E*), although the amounts are small. Nelson *et al.*[35] found only 4–10γ per 100 ml. of whole blood in resting normal subjects.

Even if the aggregate of data from such investigations would prove to be of considerable value, it is unlikely that their interpretation could adequately decide orders of precedence in events, so that considerable animal experimentation is clearly required.

Investigations on Animals

Rats. It has been postulated that the general stressful conditions of flight lead to a sustained increase in activity of the hypothalamic-pituitary-adrenal axis; it is known that an intravenous injection of adrenocorticotrophic hormone leads to an increase in output of hydroxycorticosterone within 10–20 min., and that continuous infusion of the same amount of adrenocorticotrophic hormone leads to a sustained rise in adrenal output.

Though enough is known about the peripheral or somatic actions of corticosteroids, very little is known about their action on the central nervous system and nothing about the stability of the feed-back control of the enhanced level of cortico-steroids on man. It is evident from animal data that there is a neurohumoral loop of some magnitude which should have some central as well as peripheral actions, but which has a delay of minutes and is therefore probably concerned with metabolic rather than primary nervous activity. For example, this loop might be concerned with the maintenance of arousal but scarcely with rapid alterations in the level of arousal.

Vogt has speculated that the rich content of sympathin, in the reticular system and hypothalamus, may have a behavioural function; reduction in content is caused by the administration to dogs of drugs known to effect stimulation of the sympathetic nervous system and the reflex release of adrenaline. Purpura[36] has demonstrated, in cats with crossed circulations, the persistence of arousal or electrical excitability of the cortex, after cessation of stimulation of the bulbar reticular formation in the ipsilateral animal. He also demonstrated similar effects in the unstimulated animal, but with a delay of 30–80 sec.

It is possible, therefore, that stress, by causing increased activity in the brain stem reticular formation and a reflex secretion of adrenal medullary hormones, influences cortical activity in a non-specific manner. Intense stimulation of this second hormonal loop within a generally stressful environment, which has already resulted in enhanced activity in the production of corticosteroids, may have some relationship to abnormalities in behaviour.

There are many factors which are still unknown. The role of the limbic system of the brain has received much attention in various aspects of responses to stress, particularly with reference to emotional behaviour; but little is known of its possible relationship to the hypothalamic control of hormonal output, except that the reticular system is probably implicated. Again, the relationship of the sympathica-adrenal medullary system to the pituitary adrenal cortical system has many puzzling factors. In man, Sandberg *et al.*[37] found no effect from the infusion of adrenaline on adreno-cortical secretion but Harwood and Mason[38] found a fairly marked effect on the dog.

It is therefore proposed that studies be carried out on the possible relationship of various aspects of behaviour and the activity of the brain-stem reticular formation as determined indirectly by its sympathin content or by the output of cortico-adrenal steroids.

Beach[39] found that morphine injections result in a significant increase in exploratory behaviour in rats, as compared to a control group, but not as compared to a hungry group. He considered that this effect was probably due to lowering of perceptual threshold through increased activity of the reticular formation of the brain stem, but he did not relate his findings to those of Vogt[40], who found that morphine caused loss of hypothalamic sympathin with concomitant secretion from the adrenal medulla.

Again, Petrinovitch and Bolles[41] found in studies on delayed alternation in rats that 12 out of 16 animals met the criterion of learning—the remainder could never learn to alternate their responses on the *T*-maze. These animals were subjected to a water deprivation schedule and it was found that in order to develop the delayed alternation response to its full, a loss in body-weight of 20 per cent was necessary. Although it was concluded that memory served as a cue for the correct response, no further investigation was made into the failure in training of the four rats which did not lose weight.

Thirst schedules are used in many comparative psychological investigations in order to induce a learning set, but the probable physiological processes involved are infrequently considered. Hunger is usually considered as a drive. However, Hebb[42] has equated drive with arousal on the hypothesis that an increase in drive or arousal from a low to a moderate level and likewise a decrease from a high to a moderate level will favour the learning of responses.

All initial handling of rats should therefore be considered as stressful, and the physiological literature abounds in warnings that even methods of examinations involving taking of blood induce an eosinopænia. The literature of this aspect of psychology is also large; not only does constant handling affect growth and resistance to stress, but it also affects behavioural performance, such as reduction of numbers of errors in re-learning on a water-filled closed-field maze.

It would appear to be worth while investigating the influence of some of those methods used in physiological psychology on, for example, the corticosterone content of rats' adrenals, the animals being killed by rapid decapitation, analysis being carried out by paper chromatography[43]. Holzbauer[44] has demonstrated that, in decapitated rats, the hormonal stores of the adrenal cortex reflect the secretion-rate at the time of death. She found significant variations between unstressed rats belonging to different colonies; but the largest differences were between stressed and unstressed rats.

For example, the influence on intelligence of rearing rats in a free environment, as determined by the closed-field test of Rabinovitch and Rosvold[45], should be re-investigated , if there should be any correlation between corticosterone secretion and behaviour under these conditions, then it might be possible to show some relationship between the response of the adrenal cortex and 'brightness' and 'dullness' within similar strains

Dogs The biochemical properties of the adrenal cortex of each species are probably specific and genetically determined The secretion of the rat is unlike that of most other experimental animals and also of man, but those of the dog and the monkey are sufficiently similar to man, since a large proportion of the total secretion would appear to be compound *E*

Consideration should therefore be given to the dog as an experimental animal, if results of significance can be derived from experiments with rats

The general plan of these further behavioural studies might well follow that of Thompson and Heron[46], who investigated the effects of early experience on both the problem-solving capacity of dogs and on exploratory activity They found that the dogs reared in an environment which was restricted in perceptual content evinced significantly greater activity, but had a permanent decrement in intelligence compared to their litter mates which were reared in a normal environment

24-hr food deprivation schedules were used in trials on delayed reactions and it can be postulated that the stress of testing was different in the two groups

In four normal dogs, delays of 240 sec were achieved after an average of 230 trials, but the restricted dogs could not achieve any delay If a modification of Vogt's technique[40] for the estimation of sympathin in the central nervous system were used, then it might be possible to relate the sympathin content of the reticular formation and the intralaminar thalamic nuclei to differences in behaviour

If the sympathin content were higher in the normal dogs, then it could be deduced that the impaired learning of the restricted dogs was related to the activity of the reticular formation , but further experimentation would be required to relate the strength of drive or of drive reduction to learning

A series of investigations on learning set might provide more data of significance It is known that stimulation of the central median nucleus of the thalamus (non-specific) produces facilitation of cortical sensory neurones[47] , also stimulation of intralaminar nuclei may interfere with learning If these findings be related, then during the formation of learning set, two physiological processes may be involved—the determination of the motor response by the linkage of the appropriate active cell assemblies and the progressive reduction in the activity of the arousal system

Determination of this latter by Vogt's techniques might be more meaningful to behaviour studies than micro-electrode techniques

Summary

The future problems in aviation medicine are subtle and difficult Many are concerned with the determination of behavioural responses to neurogenic stress in conditions where it is impossible to reproduce fully this stress on the ground It would appear that studies on man should be supplemented by animal investigations and that a multi-disciplinary approach would enable adequate theories to be constructed on the relationship of alterations in perceptual learning to stress

With the verification of such theories or important parts of them, it should be possible to derive new selection processes for personnel involved in future flight or extra-terrestrial travel

A BONE IMPLEMENT FROM STERKFONTEIN

By Dr. J. T. ROBINSON

Transvaal Museum, Pretoria

A MEASURE of controversy has been aroused by Dart's thesis that *Australopithecus* used bones, horns and teeth as implements. Evidence for this view has mainly come from Makapansgat, but it is the purpose of this article to report the discovery of a bone implement at Sterkfontein. This single find supports Dart's view in proving that bone was employed artificially in the Transvaal during the known australopithecine period ; on the other hand, whether this new find represents australopithecine handiwork is quite a different matter.

The specimen under consideration was found on June 4, 1958, during a five-month excavation season devoted to further exploration of the Sterkfontein extension site. This abuts on, and is continuous with, the type site from which approximately a hundred specimens of *Australopithecus* have been recovered. As already reported[1,2], the Sterkfontein deposit (type plus extension sites) consists of three different breccias : (*a*) lower or type site breccia, which has yielded numerous *Australopithecus* remains but neither stone artefacts nor *Equus* ; (*b*) middle or red-brown breccia, which has yielded 228 stone artefacts, a few small pieces of *Australopithecus* as well as remains of *Equus* ; (*c*) upper or brown breccia, which is thin and patchy and has yielded *Equus* but neither *Australopithecus* nor artefacts. Where the upper breccia occurs in the area actually excavated, it is separated from the middle breccia by a thin drip-stone or stalagmite. The bone implement was wholly encased in solid red-brown (middle) breccia a short distance below the stalagmite.

The maximum dimensions of the specimen are : length, 9¾ cm. ; width, 3 cm. ; and thickness, 1½ cm. In most places the thickness is roughly a centimetre. It consists of a portion of a long bone which had been split longitudinally. One half was then apparently broken in a manner which left one end pointed. The surfaces resulting from the breaks which formed the point have become polished completely smooth, while most of the natural bone surface has retained its original appearance—except for an appreciable amount of manganous staining. The specimen was originally longer than at present. In excavating the breccia in which it was embedded, it was broken into a number of pieces, all but a very few small pieces being recovered. The butt end was apparently slightly longer before the recent breaking occurred. Evidence of ancient damage to this end suggests that the specimen had originally been even longer.

In view of the differences of opinion which exist about the reality of bone implements associated with australopithecines, it is necessary to examine the reasons for regarding this specimen as an artefact. Two common groups of agencies may produce post-mortem alteration to the natural shape and appearance of a bone. These are (*a*) natural weathering agencies, and (*b*) animals, including man.

Under (*a*) the following may be considered :

(1) *Water*. This could have acted by rolling and abrading the specimen while loose—in a stream-bed, for example. This action would first affect all ridges or other prominences. This is not true of the specimen in question. The most marked smoothing is not on ridges, and at least one fairly delicate ridge is present and scarcely affected. Most of the surface has not been smoothed at all. Rolling may thus be discounted. But water may also have affected the specimen in another way. If the bone became partially exposed by weathering of the breccia, the exposed portion could have been smoothed by sand-bearing water flowing over it periodically while the protected portion remained unaffected. This can also be discounted, since the smoothed portions are related to the unsmoothed portions in such a way that the one could not have been exposed without at least some of the other also. Furthermore, the entire specimen was in solid breccia overlaid by a stalagmite as well as a later breccia. All other bone in the immediate neighbourhood was fresh and showed no signs of artificial smoothing.

(2) *Wind*. Wind-blown sand particles can readily smooth off rock, glass, bone and other such objects.

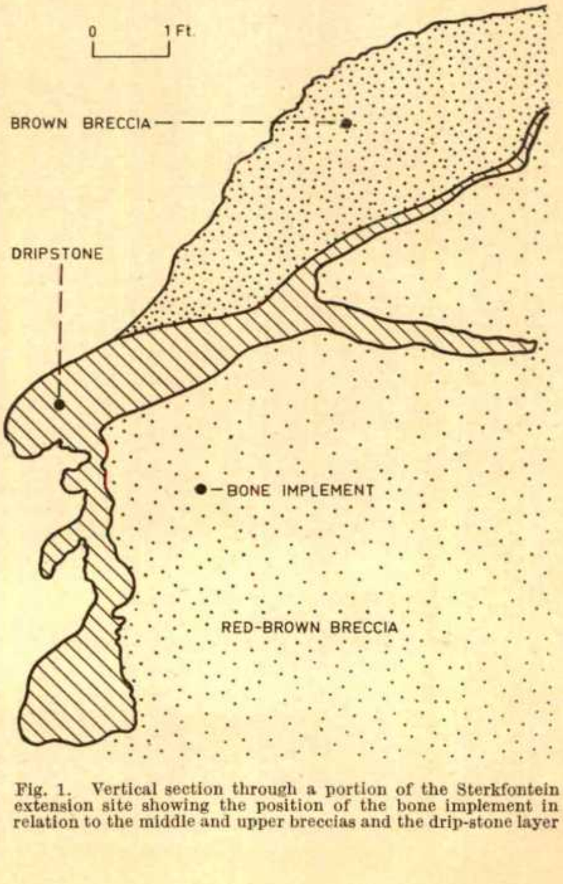

Fig. 1. Vertical section through a portion of the Sterkfontein extension site showing the position of the bone implement in relation to the middle and upper breccias and the drip-stone layer

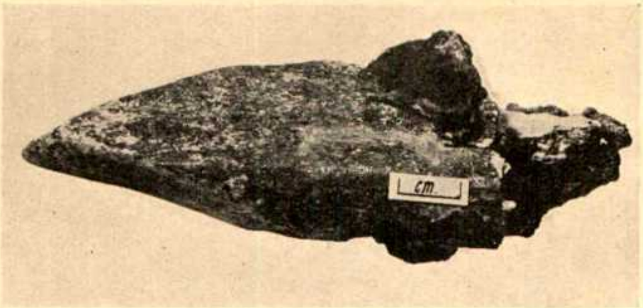

Fig. 2. Bone implement from Sterkfontein. Some breccia is still adhering to the specimen

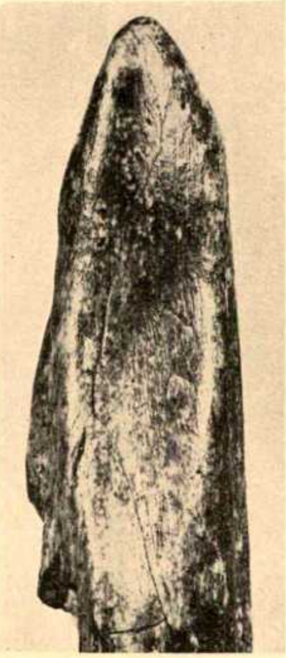

Fig. 3. Enlarged view of apex of the Sterkfontein implement, showing one of the two main polished surfaces

However, this mechanism is indiscriminate in that all exposed parts are affected. The marked localization of the smoothed areas on the specimen and the relationship of smoothed to natural surfaces render wind action improbable in the extreme. Furthermore, the action of blown sand is to produce a fine frosting on the affected surfaces, not a smooth polish.

The nature, relative size and distribution of the artificial surfaces and the circumstances of preservation eliminate also the remote possibility of chemical weathering.

Under (*b*) may be considered :

(1) *Carnivores.* The carnivores which commonly chew bones and which could conceivably be concerned in this instance are hyænas, the larger cats and the dog group. All these splinter the shafts of long bones or consume them entirely. It is impossible to see how any of them could produce either the shaping or the polishing here involved.

(2) *Rodents.* Some modern rodents gnaw bones found lying about, especially in caves. This is particularly true of porcupines, and many fossil bones bear witness to the antiquity of this activity. Unwary observers may be misled by such bones as they are often gnawed along the shafts to produce a sharp edge or around the broken ends of shafts to produce chisel edges and similar effects. Examples occur among the bones found at Hopefield[3]. However, the unmodified results of porcupine gnawing are fairly easy to detect since the marks made by the chisel-shaped incisors are visible. Where weathering has afterwards smoothed the bone, the gnawing may not be easy to detect—as in the case of some of the Hopefield bones which occur in shifting, loose sand where smoothing may thus occur easily.

This cannot be the explanation of the nature of the Sterkfontein specimen. There is no trace whatever of gnawing anywhere on the bone. If the smoothed portions are regarded as areas of weathered porcupine gnawing, then it is difficult to explain why the other parts of the bone are totally unweathered, since a marked degree of weathering would be necessary to remove all traces of gnawing. Examples of rodent gnawing do occur in small numbers in this site and an example is shown in Fig. 5. But neither this nor any of the other bones so far found in this site exhibit the marked differential smoothing found on the bone under discussion.

There appears to be no other reasonable explanation than that a hominid used the bone in a manner which polished smooth the surfaces utilized and did not affect the other parts. This is certainly the immediate impression given by the appearance of the specimen. It does not seem likely that it was used for digging, since soil would affect all surfaces of the specimen at the digging end and would also produce a more scratched surface than is the case. The only possibility seems to be that it was used for scraping or rubbing something with a definite and fairly soft surface—for example, the under-surface of animal skins. Under a stereo microscope a small amount of very fine scratching is detectable on the polished surfaces. This is much finer than that to be seen on Natufian bone implements from Mount Carmel, which show clear evidence of having been shaped deliberately, some of the shaping having been done with a blade of some sort ; some of the other surface marks on these specimens may either have been made with a stone blade with an uneven edge or be the result of use. There is no evidence of cutting on the Sterkfontein specimen.

It seems, therefore, that the characteristics of the Sterkfontein specimen can only be explained as a by-product of intelligent hominid behaviour. As

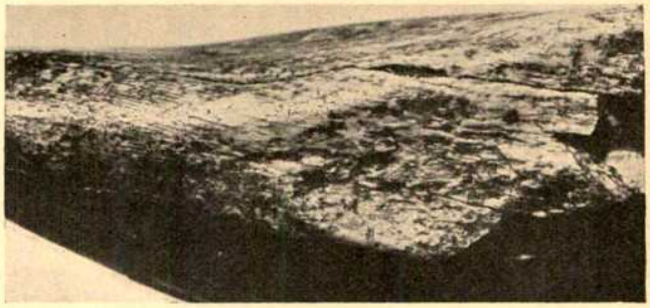

Fig. 4. Enlarged view of a portion of the Sterkfontein specimen showing a shallow oval hollow (near centre) with completely unsmoothed surface partly surrounded by polished surface

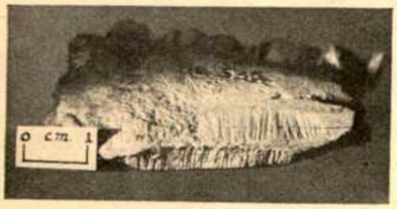

Fig. 5. Fragment of fossil bovid mandible, from Sterkfontein extension site, which had been gnawed by rodents

such it is the first clear-cut example of the utilization of bone from the Sterkfontein area and probably the best at present known from the australopithecine era. It certainly appears to be clear evidence of the artificial utilization of bone at that time-level. Since this specimen came from the same breccia which has yielded the stone artefacts from this site, it must presumably for the present be attributed to the makers of the latter. In my opinion[1,2], *Australopithecus* is unlikely to have made the stone artefacts—it seems more likely that *Telanthropus* was responsible. Probably, therefore, the latter was also responsible for the bone tool. It is not impossible, in view of the evidence accumulated by Dart, that *Australopithecus* had an 'osteodontokeratic' but not an established stone culture, but that *Telanthropus* did have the latter. If this is the case, it is possible that the Sterkfontein bone tool, but not the stone industry, was of australopithecine origin. It is, in any event, interesting to note that the specimen came from the back portion of the cave, as it was at the time of accumulation, among a mass of bones. The remainder of the deposit at that level has a much smaller proportion of bone.

I am indebted to the director of the Archæological Survey and to Dr. R. Mason of the same organization for the loan of Natufian bone implements from Mount Carmel for comparative study.

CHEMISTRY IN THE PRESERVATION OF ANTIQUITIES

AT a joint meeting of Sections B (Chemistry) and H (Anthropology) held during the York meeting of the British Association, Dr. A. E. A. Werner and Mr. R. M. Organ of the British Museum Research Laboratory discussed the subject of chemistry in the preservation of antiquities.

Dr. Werner said that the application of the chemist's specialized knowledge to the problems that arise in the preservation of antiquities may be taken to involve, first, the recognition of the symptoms of deterioration exhibited by antiquities and the realization of the ultimate causes for this deterioration expressed in terms of the physical and chemical structure of the object, and, secondly, the evolution of sound methods of conservation based on theoretical considerations and tested by practical experimentation—preferably, of course, on trial pieces or objects of minor importance specially acquired for the purpose.

In the past, the methods used in the conservation of antiquities were largely of an empirical nature and the materials used were limited to those of natural origin which approximated most closely, in their chemical and physical properties, to the needs of the particular work in hand. Typical examples of such materials are waxes such as beeswax and paraffin wax, natural resins, and animal and vegetable glues. However, in the past three decades or so, there have been remarkable advances in high-polymer chemistry which have led to the introduction of many new synthetic materials, possessing a combination of chemical and physical properties not normally found in materials of natural origin. The assessment of the potential value of these synthetic materials in the elaboration of more reliable methods for the preservation of antiquities was discussed with special reference to specific problems in the preservation of antiquities of an organic nature.

One outstanding problem is the question of the most suitable method for the treatment of wooden objects which are obtained from excavations in a so-called water-logged condition. Old water-logged wood may have a water content of more than 100 per cent of the dry matter in the wood, and its actual physical state will depend upon the degree of degradation, that is, the extent to which the cellulosic cell-wall structure has broken down. If this has reached an advanced stage, the wood will be quite soft, almost like cheese, and will have a very low mechanical strength. In considering the problem of stabilizing old water-logged wood, there are two factors to be considered. The first involves the actual removal of the large excess of water without causing serious deformation of the wood, and the second involves the consolidation of the wood to restore sufficient mechanical strength so that it can be handled with ease.

If the water is allowed to escape by ordinary evaporation, surface tension forces exerted on the weakened cell walls will cause them to collapse. Hence, special techniques have been evolved. One such technique is the so-called alum process, in which the wood to be treated is immersed in a supersaturated solution of alum at a temperature of about 95° C. until complete impregnation is achieved. The idea behind this method is to replace the water by a solid, alum being used because it can be dissolved in a very small amount of water. A more refined method is the use of the well-known biological technique for drying tissues by immersion in successive baths of ethyl alcohol followed by immersion in baths of ethyl ether. If the final ether bath contains a resin such as dammar in solution, the resin will remain after evaporation of the ether to stabilize the wood structure. This is a relatively expensive process and involves a serious fire risk, so that it is confined, in practice, to the treatment of small objects, where it has been found to give excellent results. The well-known technique of freeze-drying can also be applied. The water is frozen to ice which is evaporated from the wood under vacuum, so that any tendency for the cell-wall structure of the wood to collapse due to exertion of surface tension of *liquid* water is avoided. Experiments made in the British Museum have shown, however, that the results are unreliable, and the method is very slow and time-consuming, since it requires more or less constant supervision unless an expensive automatically controlled refrigerating unit is installed.

Since none of the above techniques may be regarded as being uniformly successful, experiments have been in progress in the British Museum Laboratory based on the use of the synthetic polyethylene glycol waxes. These waxes, although possessing the characteristic physical properties of waxes, have the rather unexpected property of being soluble in water. They are available in a polymeric series ranging from soft waxes rather like 'Vaseline' to hard waxes similar to the typical paraffin waxes. It has been found that the wax of average molecular weight 4,000 (the actual material used is known by the trade name of 'Carbowax 4000' produced by Union Carbide Chemicals Co.) is suitable for the treatment of water-logged wood. The new technique which has been evolved consists in immersing the wooden object in a 12 per cent aqueous solution of the 'Carbowax 4000' at room temperature and slowly increasing the temperature to *c.* 60° C. over a period of many weeks. The water in the wood slowly diffuses out and is replaced by the wax. During the period of treatment, the solution is allowed to evaporate so that at the end the wooden object is lying immersed in molten 'Carbowax'. This technique is particularly suitable for wood which has suffered a considerable degree of degradation while in the water-logged state and is in a spongy condition.

If the structure of the water-logged wood has not suffered too severely, and still retains a certain degree of structural strength, an alternative method of treatment can be adopted. The wooden object is allowed to dry out slowly by being placed under conditions of gradually decreasing humidity. Under these conditions, the wood will dry without suffering distortion apart from a slight flaking of the surface layer. Consolidation is achieved by impregnation with an epoxy resin which is brushed on to the wood as a mobile liquid which readily permeates the wood, where it solidifies *in situ* at room temperature, thus conferring upon the wooden object the necessary mechanical strength. These epoxy resins, which have the highly desirable property of setting to a solid without undergoing appreciable contraction, are of general application as agents for the impregnation of wooden antiquities which are in a fragile state, for example, wooden objects which may have been severely weakened as the result of attack by insects.

In the case of leather objects which may be recovered from excavation in a fragile state as the result of being water-logged, or in a brittle condition due to excessive desiccation, immersion in molten polyethylene glycol wax of grade 1,500 at a temperature of about 45° C. affords a simple method of preservation. The hydrophilic wax removes the water and consolidates the water-logged leather, whereas in the case of the brittle leather, the absorption of the polyethylene glycol wax restores to a marked degree the flexibility of the leather so that it can be handled with ease and, if necessary, reshaped without fear of breaking. Two other synthetic waxes which have proved of value in the formulation of a wax mixture for the surface protection of antiquities are the microcrystalline waxes which, owing to their special physical structure, are superior to the conventional paraffin waxes and the hard polyethylene waxes of relatively high melting point.

Another field in which new synthetic materials have found extended use in conservation is that of adhesives. When considering the use of adhesives in the restoration of fragile antiquities, the single factor which is of major importance is the question of the amount of shrinkage which can occur when an adhesive sets ; if this is large, strains are set up which may weaken the bond or cause distortion of the bonded complex. In this respect the most suitable adhesives are those based on epoxy resins ; these represent a class of adhesive which sets by chemical reaction *without* the loss of any volatile material.

The presence of soluble salts which have been absorbed by porous objects while buried in the earth prior to their excavation—for example, Egyptian ostraka—may be the latent cause of deterioration. When such objects are exposed to atmospheric conditions in which there are large fluctuations in the relative humidity, these salts tend to be transported to the surface where they crystallize out, thus obscuring the surface and, in the course of crystallizing, causing the surface layer to flake away ; in the case of ostraka, this would result in the loss of the actual writing. These soluble salts can be removed by the simple process of washing in water ; but, before carrying out the washing, it is necessary to consolidate the surface of the object in order to prevent any flaking away of the surface. This consolidation can be readily achieved by the use of a special soluble modified nylon—a material produced by Imperial Chemical Industries, Ltd., under the trade name 'Maranyl soluble nylon polymer *C* 109/*P*'. This material is soluble in either methyl alcohol or ethyl alcohol, and when a 5 per cent solution in one of these solvents is brushed on to the object prior to washing, it deposits a surface film which is not only permeable to water (thus permitting elution of the soluble salts), but also possesses a marked degree of flexibility so that it does not exert any undue contractile force on the frail surface layers. This material also possesses adhesive properties which render it very suitable for the reattachment of flaking paint on wall paintings. It was used, for example, in the treatment of a fragment of a tempera wall painting from a tomb at Thebes of the XVIIIth Dynasty in which the paint layer was tending to blister badly. A warm 5 per cent solution of soluble nylon was brushed over the areas of flaking paint and gentle pressure applied. The alcoholic solution, having a much lower surface tension than an aqueous solution, readily flows into the minute cracks in the blisters and spreads out underneath the flakes of detached paint, drawing them back into position ; in this way a secure bond was formed between the reattached paint and the ground. Furthermore, the surface film has a matt appearance so that it does not leave an æsthetically undesirable sheen on the treatment areas of the painting.

Mr. Organ dealt with the problems that arise in the preservation of bronze antiquities. He first described the causes of corrosion and the build-up of the corrosion layers. Metallographic examination shows that in the majority of bronze alloys the metal consists of a two-phase system. Prior to excavation, these contiguous phases have often been in contact with water which had percolated through the soil and contained dissolved salts. An electrolytic system is thus set up in which one of the two phases corrodes to form insoluble salts which are deposited on the surface of the object in the form of minerals which comprise the well-known 'patina' characteristic of antiquities Cross-sections of a corroded bronze were shown in illustration

The occurrence of the so-called 'bronze disease' in museums is connected with the presence of cuprous chloride as a component in this mineral structure This material not only reacts with moisture and oxygen in the air to form basic cupric chloride (which is the light green material that appears as the characteristic spots of bronze disease) but also attacks the underlying bronze with the formation of cuprite Hence action directed towards preserving a bronze object must be aimed at nullifying the activity of this particular salt

In those cases where it is desirable to retain the mineral patina on a bronze, the reactivity of the cuprous chloride may be overcome by the use of special chemical reagents, namely, (*a*) sodium sesquicarbonate solution or (*b*) specially prepared solid silver oxide

In the first method the object is immersed in successive solutions of sodium sesquicarbonate, which has little visible effect on the patina, but is sufficiently alkaline to neutralize the hydrochloric acid produced when the cuprous chloride is slowly converted into cuprite $2\,CuCl + H_2O \rightleftharpoons Cu_2O + 2HCl$ The second technique, involving the use of silver oxide, was specially developed in the British Museum Laboratory for the treatment of objects which for some particular reason cannot be immersed in an aqueous solution, for example, a bronze object inlaid with enamel-work The aim of this procedure is to seal off the corroding areas containing cuprous chloride by applying over them a layer of silver oxide powder which reacts to form an impervious layer of silver chloride

When it is desirable to remove patina, which may be not only unsightly but also concealing valuable detail on the object, the various layers of mineralization can be successively removed by chemical means First, the green basic carbonate is dissolved by immersing the object in alkaline Rochelle salt, then the cuprite is destroyed using dilute sulphuric acid, and, finally, the cuprous chloride layer is removed by cathodic reduction in alkaline solution When this treatment has been completed, there will still be residual chlorides remaining in the porous metal, these must be removed completely if the object is to remain in a stable state under normal museum conditions This can only be successfully achieved by a special process of intensive washing in many successive baths of distilled water The progress of the washing is followed by measuring the electrical conductivity of the successive baths of wash-water until it falls to a minimum and the absence of chloride is established It has recently been found that this process, which used to take up to eight months for completion, can be speeded up by a factor of as much as ten by the use of ultra-sonics

When the mineralized layers are removed, the object may sometimes be in such a frail state that some form of mechanical support is necessary In the past, material such as wood or plaster and adhesives such as shellac and nitrocellulose were pressed into service *faute de mieux* An improved technique was recently developed in the British Museum Laboratory using a suitable epoxy resin which can be supplied as a liquid which sets *in situ* to form a reinforcement This material is ideal for the purpose because it adheres well to the metal, sets without shrinkage so that no contractile stresses are exerted on the fragile object, and it is transparent so that no details of design are obscured This technique was successfully used to strengthen a unique silver hanging bowl excavated at St Ninian's Isle, Shetland, which, after removal of corrosion products, was as thin as an egg-shell

A E A WERNER

GENETICS AND THE ORIGIN OF SPECIES

TO assess the magnitude of Darwin's contribution to biology one hundred years after the publication of "The Origin of Species", it is necessary to recognize that Darwin developed his ideas in a very different climate of biological thought from our own Darwin's recognition of the dynamic nature of species was made at a time when species were regarded as the static products of natural creation

Species, as aggregates of individuals subject to variation and constantly being replaced by those of their progeny which escape from the hazards of their environment, represent a concept which we owe to Darwin and which still lies behind our knowledge of evolution

Modern theories of genetics have sprung from Mendel's demonstration of the particulate nature of inheritance and the subsequent discoveries that the hereditable determinants, or genes, are located in the chromosomes The idea that genes are subject to mutation and liable to re-assortment at meiosis represents the crude mechanism of the variation on which natural selection must operate, but behind this lies the more fundamental aspect of gene evolution and the biochemical mechanism of their operation

If the symposium in Sections D (Zoology) and K (Botany) of the British Association at the recent York meeting gives an insight into modern evolutionary thought, it is clear that geneticists are at present largely concerned with the manner of gene action and the process of modification in genetic constitution which selection induces Several speakers pointed out that the precise effect of a gene is modified by the genetic environment of the gene so that successful species come to possess a highly integrated gene-assemblage As Prof K Mather (Birmingham) emphasized, the main features of an organism affected by selection are controlled by swarms of genes acting together The effects of separate genes are balanced, and selection shifts the balance, giving gradual and not jerky evolutionary change Moreover, it is only in this way that we can understand how an organism can achieve the complex selection-advantage we find, for example, in mimicry, where a strong degree of visual similarity with the model must be obtained before selection will operate In the case of the African butterfly, *Papilio dardanus*, in which the female mimics several models, Dr P M Sheppard (Liverpool) described how the range of variation in mimic characters of the progeny of hybridization of geographical races indicated polygenic control Dominance of mimic features has been selected, so that hybrids between races which naturally meet ensures mimicry in offspring, in hybridization of races which do not naturally meet, this dominance is lost, but reasserts itself when replaced in its original genetic environment by progressive backcrossing to the race which originally possessed it

Re-adjustment of the gene-complex under the pressure of selection will account not only for change within a species with the passage of time, but also for divergence of parts of a species Any tendency for genes not to diffuse throughout all the members of a species will encourage the development of restricted gene-complexes In introducing the symposium, Prof J Heslop-Harrison emphasized that these barriers to gene-flow, or isolating mechanisms, are of several types

Physiological isolation by hybrid failure or sterility is the main genetic criterion by which species status is recognized, and this may be attained at a single evolutionary step in cases of polyploidy

Dr R Riley (Plant Breeding Institute, Cambridge) directed attention to the high frequency of polyploidy in plants, where successful polyploids usually arise by the combination of genomes, which, even if derived from the same species, are sufficiently different to allow diploid behaviour (chromosome pairing) to be established at meiosis Dr Riley showed how cytogenetical techniques had allowed the three genomes present in common wheat, which is hexaploid, to be identified as those of *Triticum monococcum*, *Aegilops speltoides* and *A squarrosa* By taking advantage of chromosome deficiencies, the mechanism controlling genetic isolation in wheat had been located and the way opened for hybridization with other cereals

Isolation by breeding preference was discussed by Dr A J Bateman (Christie Hospital and Holt Radium Institute, Manchester) Experiments with the fly *Drosophila*, where a choice of mating partner is offered, indicate that, for example, body-colour mutants influence preference Field observations of nesting pairs of birds where a plumage-colour variant is present have shown similar preference to operate in natural populations Constancy of pollinator in plants must play a similar part as, for example, between the two campions, *Silene dioica* and *S alba*, which are respectively bee- and moth-pollinated

In both outbreeding plants and animals, however, spatial isolation by ecological or geographical factors is the most widespread external mechanism which allows initial divergence either by chance restriction of genes in limited populations, or because ecological conditions differ between populations or their parts The nature of soil preference and importance of competition were discussed by Dr C D Pigott (Sheffield), who described the manner of elimination of *Vaccinium vitis-idaea* from mixed populations with *V myrtillus* and occasional hybrids, by reduction in grazing pressure after enclosure and exclusion of sheep from upland oak-woods

That divergence can precede isolation, however, is evident from experiments with *Drosophila* described by Dr J M Thoday (Sheffield) By disruptive selection (elimination of the mean phenotypes and retention of extremes) within a single breeding population over several generations, a steady trend of divergence of the extremes is produced Furthermore, experiments, in which the most extreme individuals are those used for breeding, demonstrate that this difference can be maintained

Experimental studies of this type demonstrate very clearly that evolution is no longer a theory propounded by Darwin but an indisputable fact

C D PIGOTT

OBITUARIES

Dr. Louise Pearce

DR LOUISE PEARCE, former associate member of the Rockefeller Institute, who had worked there from 1913 until 1951, died in New York City on August 9 at the age of seventy-four years Having graduated M D at the Johns Hopkins University in 1912, she began in 1913 her chemotherapeutic studies in association with W H Brown of the Institute A few years previously Ehrlich had had great success in the treatment of disease, including syphilis, with organic arsenicals In collaboration, these two workers studied experimentally the effect of arsenical compounds on laboratory infections in animals with the parasite causing African sleeping sickness One compound of this series, namely tryparsamide, prepared by Jacobs and Heidelberger in 1919, proved very effective against rabbit syphilis and was able to save the lives of animals infected with the pathogenic African trypanosomes Tests on the response of the human disease to this new substance were now urgently required Louise Pearce, of resolute character and endowed besides with great physical strength and vigour, was chosen to go out to the Belgian Congo in 1920, where thousands of natives were dying of the disease, and there carried out the tests at great personal risk

The success of the new drug was soon obvious and, as Peyton Rous has written, "she brought about one of the most shining and spectacular of the early purposeful achievements of the Institute, the conquest of sleeping sickness" Tryparsamide owes its importance to the fact that it can reach the cerebrospinal fluid in considerable concentration and has the capacity to affect trypanosomes in the central nervous system For this work Dr Pearce was awarded in 1953 the King Leopold II prize of 10,000 dollars and made an officer of the Royal Order of the Lion, having previously received the Belgian Order of the Crown Her colleagues, W A Jacobs, M Heidelberger and W H Brown, were also honoured With the last-named she discovered a rabbit cancer, known as the Brown–Pearce carcinoma, which could be transplanted to other rabbits and has proved of considerable value experimentally The virus causing rabbit pox was another of her discoveries

She was keenly interested in medical education and served during 1946–51 as president of the Women's Medical College of Philadelphia Besides her successful mission to Africa she served as visiting professor of medicine at Peiping Union Medical College during 1931–32 Her interests were wide and embraced many aspects of national and international life As an officer of a number of organizations concerned with the study of bacteriology, medicine, tropical medicine, cancer and other diseases, she proved a good citizen of the world

During her life-time she was awarded a number of honorary degrees and prizes Her monograph "The Treatment of Human Trypanosomiasis with Tryparsamide", published by the Rockefeller Institute, is a classic

J D FULTON

Dr E S Duthie

DR EDWARD STEPHENS DUTHIE died on June 9 at the age of fifty-two He was an experimental and clinical pathologist with an exceptional range of talents Born in Kilkenny, he won a sizarship in mathematics to Trinity College, Dublin, and graduated in arts, medicine and science He began biological research under Prof J B Gatenby in Dublin and continued under Prof A E Boycott at University College Medical School, London, where he went as Graham Scholar in 1933 His published work during this period was concerned mainly with the mechanism of glandular secretion While convalescing from tuberculous pleurisy in Italy he wrote a paper on the origin, development and function of the blood cells in certain marine teleosts

After a brief interlude as assistant pathologist at the University of Sheffield, he joined the staff of the Dunn School of Pathology, Oxford, and collaborated with Chain in a study of 'spreading factor', which they identified as hyaluronidase Duthie was unfit for military service during the War so he worked as hospital pathologist at Northampton until he was recalled to Oxford to help Sir Hugh Cairns, he organized and took charge of all the chemotherapy at the Radcliffe Infirmary and at the Military Hospital for Head Injuries His development of penicillinase, his work with Chain on the theory of action of penicillin and his demonstration of the influence of pH on the activity of streptomycin, have all contributed to the rapid progress of chemotherapy

Duthie took charge of the Serum Department of the Lister Institute in London in 1946 and worked on serum and bacterial proteases and their inhibitors In 1948 he was appointed deputy director of pathology at Southampton, becoming director in 1952 During the past ten years he studied various products of the staphylococcus His crowning achievement was the purification of coagulase—the first blood-clotting substance to be purified

Duthie's integrity, sympathy and kindness were apparent to all who met him, his friends knew his generosity, his concern for refugees and all who were oppressed, his appreciation of art and music and his courage and cheerfulness in the face of prolonged ill-health

CHARLES H LACK

Mr John Cecil May, C M G , O B E

BY the death on September 10 of J C May, director of the Empire Cotton Growing Corporation, tropical agriculture has lost one of its wisest and most distinguished administrators of agricultural research His background of geology and forestry at Oxford, and of the administrative service in Nyasaland and Tanganyika, was singularly appropriate for the development of his life's work in an independent corporation engaged in research in tropical territories His judgment and enthusiasm were largely responsible for the high standard of recruitment to the Corporation's service, and his sympathy and understanding for the welfare of his staff in the diverse circumstances in which they work He understood the needs and difficulties as well as the responsibilities of government departments, and his breadth of interest was the foundation of the co-operation between government officials and the research staff of the Corporation that has been so fruitful in the extension of the cotton crop in African territories His vision and grasp of practical needs and possibilities enabled the Corporation to continue to provide staff for the Sudan when the Republic of the Sudan was established In planning the British contribution to technical services in the new Africa that is emerging, his counsel will be sorely missed

J B HUTCHINSON

NEWS and VIEWS

International Red Locust Control Service

THE last plague of the red locust, *Nomadacris septemfasciata* Serville, lasted from 1930 until 1944 and affected most of Africa south of the equator Field investigations by British, South African and Belgian scientists revealed comparatively small outbreak areas in Northern Rhodesia and Tanganyika In 1941 A P G Michalmore set up headquarters in Abercorn, Northern Rhodesia, and began preventive control of these areas, in 1945 H J Bredo became director of the International Red Locust Control Service This Service was established by international treaty in 1949 and the first decade of the treaty was completed on August 5 this year At first, the idea was to watch for any upsurge of locusts in the outbreak areas and then to arrange control measures, but it became clear that events moved too quickly and the Service had to be constantly ready to attack Even so, swarms escaped from the outbreak areas in most years until operational research, mainly by Haydn Lloyd, led to the design of fully effective methods of control, using very light aircraft In 1955 there occurred the largest upsurge ever recorded, it was completely controlled No swarms have escaped since 1954

Dr D L. Gunn, C B E

DURING the period 1952–59 the director of the International Red Locust Control Service was Dr D L Gunn Educated at the High School and the University College, Cardiff, he was then for seventeen years at the University of Birmingham, first as assistant lecturer and finally senior lecturer in zoology There he became known for researches on the temperature and humidity relations of insects and he collaborated with Dr Gottfried Fraenkel in "The Orientation of Animals" (Oxf Univ Press) Towards the end of the War, he was seconded to Kenya to study the behaviour of desert locusts in swarms, in relation to aircraft spraying, and in 1945 with Douglas Yeo and a team from the Chemical Defence Experimental Establishment, Porton, he carried out the first attacks on adult locusts in Africa that used liquid insecticide sprayed from aircraft In 1946 he became the first principal scientific officer of the Anti-Locust Research Centre, then newly separated, under Dr B P Uvarov, from the Commonwealth Institute of Entomology, and was responsible for starting and building up its research programme, both in the Centre laboratory and extra-murally in universities In 1947, jointly with H A F Lea (now chief locust officer of the Union of South Africa), he was responsible for successful aircraft spraying experiments against the red locust in Tanganyika In 1950 he did field experiments in Somaliland and the Sudan which resulted in the complete replacement of wet bait by dry bait for controlling the desert locust with great economies in cost In 1952 he was appointed director of the International Red Locust Control Service , in the following years, this Service was completely reorganized, made effective, and cheapened to about half its earlier maximum annual cost Dr Gunn was appointed C B E in 1958 and he now leaves Africa to become director of the Tea Research Institute of Ceylon

Mr C du Plessis

THE Council of the International Red Locust Control Service has invited Mr C du Plessis to become director, in succession to Dr Gunn Educated at Oudtshoorn and at Grey University College, Bloemfontein, he lectured in zoology at Grootfontein College of Agriculture for six years and in entomology at Glen for four years before beginning full-time research on stalk-borer at Kroonstad Soon after the red locust plague reached South Africa, he began research under Prof J C Faure, publishing mainly in the science bulletins of the Department of Agriculture, and becoming increasingly involved in control as well In 1944, locust research, locust control, and administration, were combined under the newly enlarged post of chief locust officer, to which post Mr du Plessis was appointed He was responsible for containing within the outbreak areas a prolonged upsurge of the brown locust from 1948 until 1954 , during this period, both control methods and administration were completely revolutionized Representing South Africa on the International Red Locust Control Service Council for many years, he was elected president in 1954 in succession to Mr G B Beckett, then Member for Agriculture in the Northern Rhodesia Government He retired from the post of chief locust officer in December 1958

Theoretical Mechanics at Southampton :
Prof B Thwaites

A THIRD chair of mathematics, with special reference to fluid mechanics, has been created at Southampton The first holder of the chair will be Dr Bryan Thwaites Dr Thwaites, after graduating in Cambridge with first-class honours in mathematics, spent three years in the National Physical Laboratory and was then appointed lecturer at the Imperial College of Science and Technology in the Department of Aeronautical Engineering In 1951 he became assistant master at Winchester College but maintained his contact with university teaching and research as visiting lecturer in fluid mechanics at the Imperial College Dr Thwaites has been a member of the Performance Sub-Committee of the Aeronautical Research Council and is at present a member of the Fluid Motion, Engine Aerodynamics and Laminar Boundary Layer Panels of that Council He is chairman of the Aerofoil Theory Panel and editor of "Incompressible Aerodynamics" due to be published this year His name is familiar in the form of the Thwaites flap and with his engineering interests it is expected that his appointment will strengthen the already existing ties between mathematics and engineering in the University of Southampton Dr Thwaites's wide cultural and teaching interests will be particularly welcomed in the rapidly expanding University of Southampton

Electrical Engineering at Southampton :
Prof L G A Sims

DR SIMS, head of the Electrical Engineering Department and senior lecturer in electrical engineering in the University of Southampton, succeeded the late Mr P G Spary in 1952, and he has now been made professor in the University Dr Sims studied under the late Prof William Cramp at the University of Birmingham, graduating with first-class honours and a Bowen Research Scholarship in 1924 He obtained his M Sc with an award of a research prize He joined the Research Laboratories of the General Electric Co , Ltd , under the late Sir Clifford Paterson. Later he joined the lecturing staff of the University of Birmingham, and although primarily concerned with power engineering, and founding the first electronics laboratory, he was associated with the first successful television reception in Birmingham received from the original London Baird transmitter Dr Sims initiated and directed researches at Birmingham upon the incremental properties of magnetic steels In 1936 he was appointed head of the Electrical Engineering Department of the Northampton Polytechnic in London On the power utilization and supply side, Dr Sims was one of the first engineers in Britain to be interested in energy storage with the a c system and initiated research work upon electro-thermal storage methods He has held senior teaching appointments in Government Service both at the Royal Naval College, Greenwich, and the Royal Aircraft Establishment, Farnborough During the session 1957–58 Dr Sims was chairman of the Institution of Electrical Engineers, Southern Centre His main ambition is that he and his staff shall advance the prestige of the already well-known Electrical Engineering Department in the University of Southampton, and liaison work with large industrial concerns in different parts of Britain together with new electrical courses may lead to a system of postgraduate scholarships in electrical engineering by the time of the University centenary in 1962

Physics at the University College of North Staffs :
Prof D J E Ingram

DR D J E INGRAM has been elected to the chair of physics at the University College of North Staffordshire, in succession to Prof F A Vick, who has become deputy director of the Atomic Energy Research Establishment, Harwell (*Nature*, 183, 861 , 1959) Dr Ingram was reader in electronics at the University of Southampton, where he went in 1952 to work with Prof E E Zepler, now president of the British Institution of Radio Engineers He took a first in physics at Oxford in 1948 and worked for three years under Prof B Bleaney on magnetic resonance At Southampton he extended his work on microwave spectroscopy, gathering together a team of physicists, chemists and electronic engineers, which has applied the techniques of electron resonance to a variety of problems in physics and chemistry This work has been particularly fruitful in studies of metallo-organic compounds, such as the hæmoglobin molecule, in the investigation of breakdown processes resulting from ultra-violet irradiation and in detection of free radicals in various forms of carbon Dr Ingram has also been concerned with the study of maser and mavar problems, and with the use of electron resonance in applied electronics He is the author of two books on the applications of microwave spectroscopy to physics and chemistry, and has been one of the instigators of the formation of the Radiofrequency Spectroscopy Group

Chair of Applied Mathematics at Cardiff:
Prof P T Landsberg

DR P T LANDSBERG, who has been appointed to the newly created chair of applied mathematics at Cardiff, came to Britain from Germany in 1939 He followed his bachelor's degree in the University of London by a master's degree in the field of quantum mechanics, and in 1947 he became one of the early members of Dr T E Allibone's staff at the Associated Electrical Industries Research Laboratory, Aldermaston He participated in the semi-conductor interests of the Laboratory, concentrating on the theory of electrical barriers The generosity of the Laboratory enabled him also to work at the same time for a Ph D degree under Prof H Jones on the effects of electron collisions on the soft X-ray emission bands of sodium, this investigation showed that there were long-range correlations among the electrons, resulting in an unexpected screening of the Coulomb interactions Since 1950, Dr Landsberg has been a lecturer in natural philosophy at Aberdeen, where his teaching interests have ranged from first-year practical classes to statistical mechanics at an advanced level In 1956, together with his pupil, Dr I E Farquhar, he helped to re-open the subject of the quantum statistical ergodic and *H* theorems, which were thought to have been proved by von Neumann in 1929 and later improved by Pauli and Fierz, by showing that they were based on an erroneous argument Also in 1956, Dr Landsberg published a notable paper on the foundations of thermodynamics in "Reviews of Modern Physics", and has a book appearing shortly in the same field He has maintained his interest in semiconductors, where his most recent paper, with his pupil, Dr A R Beattie, shows that electron collisions can play the dominant part in limiting the life-time of excess carriers in indium antimonide From the agreement between his theory and the experimental findings, it appears that this substance may be the first semiconductor in which the life-time has been made to approach its theoretical maximum

Festschrift for R E Snodgrass

THE whole of Vol 137 of the Smithsonian Miscellaneous Collections (Studies in Invertebrate Morphology Pp v+416+49 plates Washington, D C Smithsonian Institution, 1959) consists of a series of seventeen original articles by well-known entomologists from many parts of the world under the general title of "Studies in Invertebrate Morphology", and is published "in honor of Dr Robert Evans Snodgrass on the occasion of his eighty-fourth birthday, July 5, 1959" It is hard to think of R E Snodgrass as having reached this score He is the tough wiry Mark Twain type of American, admirably depicted in a frontispiece made last year, his ready and slightly caustic wit remains unimpaired, and he is still turning out first-class work on the morphology of insects The book contains a sympathetic biographical chapter by Dr Ernestine B Thurman, illustrated with some of the highly professional comic drawings that Snodgrass produced in his early days The scientific articles maintain a high standard throughout and many of them demonstrate the widespread influence exerted by Snodgrass as a morphologist But Snodgrass has always taught that "morphology must be intimate with function" and it is appropriate that there are several good papers on insect physiology There is plenty of good material in the volume, but it is fitting that the best paragraphs of all (pp 17–18) should be those in which R E Snodgrass himself resumes his outlook on life in a few well-chosen words

Sir Dorabji Jamsetji Tata (1859–1932)

THE leading architect in the intellectual and industrial renaissance of India Sir Dorabji Jamsetji Tata was born at Bombay on August 27, 1859, and was educated at Gonville and Caius College, Cambridge, and at the University of Bombay, where he graduated in 1882 On his father's death, he became head of the company, Tata and Sons, the largest industrial concern in India In 1911 he established the Tata iron and steel works at Jamshedpur, and in the same year founded the Indian Institute of Science at Bangalore to prepare young Indians for the direction of modern large-scale industries and for industrial research He was knighted in 1910 and served as president of the Indian Industrial Conference in 1915 A great philanthropist who rendered help without distinction of caste or creed, he gave £25,000 to the University of Cambridge in 1920 for the equipment of laboratories in the School of Engineering (he was elected an honorary fellow of his college in 1922) In 1931 he created as a memorial to his wife the Lady Tata Memorial Trust for research in any part of the world into diseases of the blood, and for work in India for the alleviation of human suffering The last of his house, he died at Kissingen in Bavaria on June 3, 1932 and was buried in the Parsi cemetery at Brookwood, Woking In 1945 the Tata Memorial Hospital was erected in the city of his birth

National Science Foundation Review of Research and Development

IN a statement on Research and Development and Economic Growth (issued as No 13 by the U S National Science Foundation in its Reviews of Data on Research and Development), Dr A T Waterman said that the Foundation's studies indicated that national research and development effort currently stood at more than 10 thousand million dollars, compared with less than 500 million dollars before the War, and had doubled since 1954 In terms of performance, industry accounted for about 70 per cent, Government about 20 per cent, and universities and other non-profit institutions for the rest in terms of finance Government accounted for rather more and industry for somewhat less than half Dr Waterman stressed the long-term significance of the economic implications of research and development, and besides the beneficial results which war expenditure on military research and development might have on the civilian economy, research and development could stimulate the under-developed economies of other countries It was the key to the two great challenges of the future the increasing opportunity to achieve our own potential growth and expansion and the urgent need to co-operate with the great under-developed countries of the world Of the 10 thousand million dollars currently expended on research and development, only about 6 per cent was on basic research. In making a strong plea for more support of basic research, especially in colleges and universities, Dr. Waterman said that this would ultimately reduce development costs by indicating the best fields of research. The Federal Government was supporting research in academic institutions but wished to see industry increasing its support for such research as well as its support of basic research in its own laboratories. Industry was the largest employer of scientific personnel, employing in January 1957 nearly two-thirds of the scientists and engineers in the United States, including 528,000 engineers, 152,000 scientists and 58,000 administrators of such activities, about a third of whom were engaged on research and development.

Scientific and Technical Personnel

THE National Science Foundation of the United States has announced that at the request of the Bureau of the Budget it will be responsible for establishing and maintaining a programme of national information on scientific and technical personnel. This will cover their training and utilization, compensation levels, supply and demand, and other related data. The Foundation will organize the register, co-ordinate and analyse all information gained, and ensure that the findings be made public. Much of the information recommended will be produced by extending existing statistical records. Other projects will have to be initiated to meet the objectives of the programme. The decision of the Bureau to ask the Foundation to organize the register arose from recent recommendations of an advisory panel on 'Scientific Manpower Data Requirements'. The panel recommended a programme of fifteen projects, of which the most urgent were considered to be: first, an identification of scientific and technical occupations; secondly, a periodic survey of organizations employing scientific and technical personnel; and finally, a periodic study of the demand outlook for various categories of scientific and technical personnel in each major activity. The last item would include analyses of employment and production growth trends and also the changing roles of particular classes of scientific and technical personnel.

Productivity Measurement in Great Britain

A REPORT by T. E. Easterfield (Department of Scientific and Industrial Research. Productivity Measurement in Great Britain: a Survey of Recent Work. By T. E. Easterfield. Pp. ii+79. London: Department of Scientific and Industrial Research, 1959) attempts to survey recent or current British studies of productivity measurement at the level of the individual factory, together with such other related work as seems particularly illuminating. Studies based on overall statistics of whole industries are included only where they throw light on the problems of more detailed studies. The report first briefly discusses the main purposes of productivity measurement: overall economic analysis and planning; planning, target setting and the forecasting of requirements of industries or firms; the spotlighting of cases that stand out by reason of high (or low) productivity; and investigation of other factors that may affect productivity, and their relative importance. The main sections are the problem of multiple inputs; the problem of multiple outputs; the study of factors affecting productivity and the translation of results for practical application.

Education in the Commonwealth

A PAMPHLET, "Commonwealth Education: The United Kingdom Contribution" (prepared for the Commonwealth Relations Office and the Colonial Office by the Central Office of Information. Text by Duncan Crow. Pp. 68+4 plates. (London: H.M. Stationery Office, 1959.) 2s. 6d.), gives an impressive picture of what the United Kingdom is already doing in this field, to which, in the twelve years April 1946–March 1958, Britain contributed under the Colonial Development and Welfare Acts £35 million in grants and loans, of which £16 million were for primary and secondary education, £6 million for technical and vocational education and £13 million for higher education. The pamphlet brings together, moreover, facts about an effort which embraces also what is being done through the British Council for the welfare of the 7,000 odd full-time Commonwealth students in the United Kingdom, some of whom are numbered among the 728 training as teachers in the United Kingdom and for the teaching of English in the Commonwealth. There is a section dealing with the Colombo Plan trainees and with the 6,566 Commonwealth students in United Kingdom technical colleges, and another with the remarkable growth of Commonwealth universities between 1938 and 1957, in which period the number of institutions has increased by 50 per cent, their teaching and research staff has trebled and full-time students have nearly quadrupled. No attempt is made to indicate the total cost to Great Britain, and, impressive as it is, the pamphlet shows clearly enough how much more remains to be done and the opportunities which interchange schemes, for example, offer for expansion.

Public Library Statistics in Great Britain

"STATISTICS of Public (Rate Supported) Libraries in Great Britain and Northern Ireland 1957–1958" (Pp. 33. London: Library Association, 1959. 7s. 6d.) gives the number of public library authorities in the United Kingdom on March 31, 1958, as 569, serving an estimated population of 51,597,000 and holding a stock estimated at 68,600,000, approximately 16 per cent being reference stock. Issues for home reading are estimated at about 431,863,000, an increase of 12,435,000 on 1956–57, and total expenditure was £17,522,000 compared with £15,906,000 in the previous year, of which £4,254,000 and £3,863,000 respectively were expenditure on books. Full-time non-manual staff numbered 12,990 compared with 12,760 in 1956–57, and at least 1,870 part-time paid staff were also employed. There are at least 32,755 public library service points in the United Kingdom, including 569 municipal central libraries and county headquarters, 1,333 full-time branches, and 30,853 part-time branches, centres, etc., as well as 200 mobile libraries.

Instrument Construction

THE Russian monthly *Priborostroenie*, which is described as a "scientific, technical and production" journal, is being produced in an English translation under the title *Instrument Construction* (No. 1, 1959. Translated from the Russian. Pp. 38. Published monthly. Subscription £6 yearly post free (17.10 dollars U.S.A. and Canada). Special rate of £3 yearly post paid (8.55 dollars U.S.A. and Canada) available to University and Technical College Libraries. Single copies 15s. each (2.15 dollars U.S.A. and Canada). London: Taylor and Francis, Ltd., 1959), by the British Scientific Instrument Research Association for the Department of Scientific and Industrial Research It covers industrial instruments and instrumentation, automatic control and production engineering for precision work and affords a valuable insight into current Russian practice in these fields The first number of the journal corresponds to the January 1959 issue of *Priborostroenie* and each issue of the English journal, because of the time needed for translating and printing, will be published two and three months later than the corresponding Russian number The contents of the first number includes five short articles from the twenty-first congress of the Communist Party of the Soviet Union The articles pay tribute to Mr Khruschev's report "Targets for the Development of National Economy of the USSR for the period 1959–65", and deal mainly with various aspects of the extension of automation in industry in furtherance of the seven-year plan The more technical articles deal with the automatic control of ferro-alloy furnaces , a transistorized analogue computer , an electronic phasemeter with a range of − 180° to 180° , and field magnets and magnetic lenses for cathode-ray tubes with cold cathodes Laboratory notes, and reviews and abstracts from the pages of the Czechoslovak journals, make up the remainder of the contents

French Journal of Science Teaching

The first edition of *l'Enseignement des Sciences* has made its appearance (1, No 1 , May–June 1959 Hermann Paris 1,200 francs per annum) , it is to be published five times a year The journal aims to cover a wide field of science instruction and to publish as much original research as possible for the "amelioration of scientific studies" The first edition consists of 48 pages with seven plates, bold line graphs and some amusing Lima line cartoons The main article, the "Known Limits of the Universe", covers eleven pages and is well illustrated Articles follow on the importance of science in education, a report on the improvements in teaching at the Nancy school of mines, and modern mathematics and their teaching An extensive review of Jean Perrin's "Éléments de la Physique" is included, also an interesting article on the philosophy of children which is based on Charles Rollin's "Traité des Études" (1726) in honour of his memory Inquiring articles also occur on perceptions of geometry, etc The journal concludes with numerous short reviews and a section of general correspondence

Atomic Energy in Australia

The contents of the December 1958 issue of *Atomic Energy* (2, No 1), the quarterly published by the Australian Atomic Energy Commission to keep industry and commerce informed of progress in the field of atomic energy, includes an article by J L Symonds describing procedures for the commissioning period of the reactor *Hifar* , a review of reports made to the Second International Conference on the Peaceful Uses of Atomic Energy in Geneva during September 1958 on nuclear power developments in the various countries , and an authoritative discussion of the power position in South Australia by S E Huddleston, assistant general manager of the Electricity Trust of South Australia He maintains, contrary to the statements of many writers, that South Australia is not in need in the immediate future of nuclear power, largely because of the determined and efficient use being made of the power resources which are at present available The only economic coalfield in the state is at Leigh Creek, some 350 miles north of Adelaide, and in 1958, 694 million kilowatt hours were produced from Leigh Creek coal by the Electricity Trust This will be stepped up when new plant becomes available and it is expected that Leigh Creek coal will be fully exploited by about 1965 The increase in demands for electricity indicates that it will be necessary for South Australia to introduce nuclear power in 1970 but a decision to build an atomic power station there may not be made for another five or six years The future of nuclear power in Australia will be governed by the relative cost of generation from nuclear and conventional sources , the relative capital investment involved , and the availability and reliability of nuclear and conventional fuel Mr Huddleston considers that South Australia will be the first of the States to need nuclear power and his careful review of the relevant factors as they affect South Australia may prove valuable in assessing the value of introducing nuclear power into other parts of Australia

The Australian Museum

The annual report of the Trustees of the Australian Museum for the year ending June 1958 (Pp 19 Sydney Government Printer, 1959) records with appreciative comment the receipt of increased financial support from the Government It also states that the clearance of temporary buildings has been carried out and that the site is now ready for the new wing which will form the continuation of the northern frontage of the Museum for which working drawings have been prepared A generous gift by Sir Edward Hallstrom will enable the lecture theatre to be re-modelled and brought up to date and thus make it of more use to the rapidly developing schools service Much field work has been carried out by members of the staff and it is interesting to note that the appointment of a public relations officer has resulted in good publicity in many media

Sierra de Tamaulipas, Mexico

Between 1945 and 1955 Dr MacNeish, now of the National Museum of Canada, led three expeditions to the state of Tamaulipas in north-east Mexico, and in a new publication (*Transactions of the American Philosophical Society* New Series, Vol 48, Part 6 Preliminary Archæological Investigations in the Sierra de Tamaulipas, Mexico By Richard S MacNeish Pp 210 Philadelphia American Philosophical Society, 1958 5 dollars) he gives the results of his work in the Sierra de Tamaulipas, a range of hills in the south of the State It was not a favourable region for the development of elaborate cultures, although it was occupied for most of the time when the high civilizations of ancient Mexico were flourishing farther south The importance of this study, which is considerable, lies in the evidence obtained from excavations in a dry cave for the cultivation of maize and squash on a small scale at the very early date of about 2500 B C , in a mainly gathering and hunting culture This is the earliest satisfactorily dated example so far known of cultivated maize, and a discussion of its botanical implications was published by P C Mangelsdorf, the author and W C Galinat in *Botanical Museum Leaflet*, Harvard University, 17 (5), 1956

African Botany

A Vegetation Map of Africa in colour, with accompanying explanatory notes by R. W. J. Keay, and with a French translation by A. Aubréville, has been published on behalf of l'Association pour l'Étude Taxonomique de la Flore d'Afrique Tropicale, with the assistance of Unesco (Oxford University Press (1959), price 15*s*. in the United Kingdom only). The vegetation concerned is that which occurs south of the Tropic of Cancer. The author explains that the aim of the map is to show the vegetation as it is to-day and not the presumed climax types. He points out that the boundaries between the zones are seldom precise on the ground although, in the interests of clarity, they are thus represented on the map. The name selected for any particular zone relates to the most widespread natural or semi-natural type of vegetation found within it. Other necessary clarifying observations are also indicated.

'Parsnip' Dermatitis

Under this title B. J. Youngman has given an interesting account of various blisters and rashes caused by certain umbelliferous species, in particular those of *Heracleum* and *Pastinaca* (*Kew Bulletin*, 3, 387; 1958). In one instance, boys who had been playing with the giant species *Heracleum mantegazzianum*, using the stout stems as swords and telescopes, developed such severe red rashes and, later, blisters, as to require hospital treatment. This species of 'cow parsnip', which may grow to a height of 12 ft. with hollow stems 4 in. in diameter, is a native of the Caucasus. Originally introduced into Britain as a garden plant, it has now become naturalized in waste places, along rivers, etc. The author also discusses the edible, acrid, and vesicant properties of other species of *Heracleum* and of *Pastinaca*, to which the domestic parsnip (*P. sativa*) belongs, and cites evidence of more or less severe dermatitis effects which have been traced to them. She also recalls that some of the Umbelliferæ have not merely acrid and scalding juices or ingredients but are virulently poisonous, for example hemlock. So far the toxic principles present in species of *Heracleum*, *Pastinaca* and other umbelliferous plants have not been isolated or identified.

The Mammals of Banff National Park, Alberta

In 1885, an area of 10 square miles around the newly discovered hot springs in the Bow Valley of the Alberta Rockies was designated as Rocky Mountain National Park. This was Canada's first national park. Since that date the park boundaries have been altered several times, and the name has been changed to Banff National Park. The present area of the park is 2,585 square miles. It stretches for 210 miles along the eastern flank of the Rocky Mountain from latitude 50° 45′ to 52° 45′ N. The western boundary is the continental divide. Six main mountain ranges, the axes of which lie north-west–south-east, are contained in the park. A survey of the mammals of the extensive area has been made by A. W. Banfield, who describes 17 species in the Cordilleran fauna, 11 in the Boreal fauna, 7 in the Prairie fauna, 1 species in the Tundra fauna, and 18 of uncertain affinities (Nat. Mus. Canada, Bull. 159, Biol. Ser., 57).

The Ophitron

The General Electric Co., Ltd., announces that a compact microwave-generator embodying a new focusing principle has been developed at its research laboratories. The valve is an electrostatically focused backward-wave oscillator which has been named the 'Ophitron', after the Greek *ophis*, a serpent, the word being suggested by the undulating path of the electron stream flowing along the structure. The most striking advantages of the new oscillator are its small size (6 in. long and ¾ in. diameter) and low weight (7 oz.), and in addition the 'Ophitron' system has been designed to be simple to construct and to operate. A single stamped-out periodic structure and two flat focusing plates form the propagating path for the radio-frequency wave, and set up the periodic electrostatic field which focuses the electron beam. The system has the fundamental advantage that the crests of the undulating electron beam are brought into the region of maximum radio-frequency field. This feature gives good coupling between beam and wave, and leads to greater bandwidth than is obtained with the equivalent magnetically focused backward-wave oscillator. The present 'Ophitron' tunes electronically over at least a 40 per cent band in the 10,000 Mc./s. region. A range of such valves is envisaged, covering most important centimetre wave-length bands. It is expected that the noise performance will be better than that of magnetically focused backward-wave oscillators due to the ion drainage from the electron beam inherent in the focusing method.

Non-Oxide Glasses

Arsenic trisulphide glass is well known as a useful material in the construction of optical parts transmitting in the infra-red. It suffers from a very low softening temperature compared with the normal type of oxide glass, and so far there is very little promise of harder glasses being prepared with sulphur or selenium as the anion. Some of these glasses are semiconductors of high resistivity, greater than 10^6 ohm/cm./cm.^{2} The Bell Telephone Laboratories have just announced an ingenious application of glasses in this family which puts to practical use the low-softening point, the property which is undesired in the other present uses. Glasses composed of varying proportions of sulphur or selenium with arsenic and thallium become very fluid at temperatures between 125° C. and 350° C. In this temperature-range the viscosities of the various glasses approximate to that of castor oil at room temperature. These materials have been found to be eminently suitable for coating small electronic devices by dipping into the castor oil-like liquid. At room temperature the materials are typically glass-like solids inert chemically to most reagents except concentrated alkalis. Several compositions are said to resist oxidation in air to above 250° C. Initial experiments in coating semiconductor devices have shown considerable promise.

Joseph P. Kennedy, Jr. Memorial Foundation

A gift of one million dollars has been made by the Joseph P. Kennedy, Jr. Memorial Foundation for the establishment of the Joseph P. Kennedy, Jr. Laboratories for research on mental retardation, at the Massachusetts General Hospital. One half of this generous gift will be spent on the construction of these Laboratories and the other half will serve as an endowment to provide continuing operating funds. This is the first of the endowed scientific researchships planned under the 1961 programme in observance of the 150th anniversary of the Massachusetts General Hospital.

Royal Society Research Appointments

Dr J S Gillespie, of the Department of Physiology, University of Glasgow, has been appointed the first Sophie Fricke Royal Society research fellow in the Rockefeller Institute, where he will work on intracellular recording from innervated smooth muscle This appointment is a new post which has been established by the Rockefeller Institute from funds left to the Institute by the late Miss Sophie D Fricke of New York City, who died on March 1, 1958 The trustees of the Rockefeller Institute have authorized use of the income from the fund for the triple purposes of fostering international understanding, training scientists of exceptional promise and supporting significant research It is the intention of the Rockefeller Institute to appoint four research fellows each year, from France, Denmark, Sweden and the United Kingdom, the selection being made by the French Academy of Sciences, the Royal Danish Academy of Sciences and Letters, the Swedish Royal Academy of Sciences and the Royal Society

A Locke research fellowship has been awarded to Dr B G Cragg, of the Department of Anatomy, University College, London, to work at University College, London, on the connexion and physiological functions of certain nuclei in the brain Stothert research fellowships have been awarded to Mr W D Butt, of the Department of Biological Chemistry, University of Aberdeen, to work at the Molteno Institute of Biology and Parasitology, University of Cambridge, on intracellular hæmoprotein compounds , to Mr R A Webster, of the Department of Pharmacology, University College, London, to work at University College, London, on the pharmacology of tetanus, and to Mr J A Hunt, of Peterhouse, Cambridge, to work on the chemical structure of proteins

Leopoldina Academy New Members

It is announced that the following, with others, have been elected members of the German Leopoldina Academy of Natural Sciences, Halle Mathematics Section, Profs Herbert C Grotzsch (Halle) and Hans Schubert (Halle) , Physics Section, Prof Otto Kratky (Graz) , Geophysics and Meteorology Section, Prof Erik Herbert Palmén (Helsinki) , Chemistry Section, Profs Gunther Rienacker (Berlin) and Wilhelm Treibs (Leipzig) , Botany Section, Profs James Bonner (Calif), William O James (London) and P Maheshwari (Delhi) , Zoology Section, Profs A W Iwanow (Leningrad), E N Pawlowsky (Leningrad) and Fritz Peus (Berlin) , and Geography Section, Profs Rudolf Kaubler (Halle) and Ernst Neef (Leipzig)

University News

London

Prof W R Niblett, director of the Institute of Education, University of Leeds, has been appointed dean of the University of London Institute of Education with the title of professor of education in the University

The following appointments to University readerships have been announced Dr D J Anderson (physiology in relation to dentistry), tenable at Guy's Hospital Medical School , Dr A Ashmore (experimental physics), tenable at Queen Mary College , Dr F Hobbiger (pharmacology), tenable at Middlesex Hospital Medical School , Dr M B Shapiro (psychology), tenable at the Institute of Psychiatry , J W Stewart (hæmatology), tenable at Middlesex Hospital Medical School , Dr D F Cheesman (biochemistry), in respect of his post at Bedford College , Dr A P Millman (mining geology), in respect of his post at the Imperial College of Science and Technology

Southampton

The University has conferred upon Prof P Ford, professor and dean of economics, who is retiring on September 30, the title of professor emeritus Prof Ford will formally open the newly completed building for the Faculty of Economics and the Ford Collection of Parliamentary Papers on October 14 Mr R G Woods, of the University Library, Cambridge, has been appointed deputy librarian The title of senior lecturer has been conferred upon Dr G W A Fowles (Chemistry), Dr J P Jones (Aeronautical Engineering) and Dr R A Pelham (Geography). The following lectureships are also announced: Dr A N Clements (physiology and biochemistry); Dr J Heading (applied mathematics) , Mr R W Page (mechanical engineering) , Dr J R Rydzewski (civil engineering) , Dr R G Scurlock (physics) , Dr E V Vernon (electronics)

Announcements

Mr J B Adams, at present director of the Proton-Synchrotron Group of the European Council for Nuclear Research near Geneva, has been appointed director of a new establishment to deal with controlled thermonuclear research The work in this field now being done at Harwell, and some of the work now being done at the Atomic Weapons Research Establishment, Aldermaston, will be moved to this new establishment when its site has been chosen

The Elmer A Sperry Award "for outstanding achievement in the field of transportation" will be presented in 1959 to the de Havilland Aircraft Co , Ltd , the creators of the world's first jet passenger transport, the British-built *Comet* Formal presentation of the award will take place in New York later this year at a joint meeting of the Institute of the Aeronautical Sciences and the Royal Aeronautical Society The award is sponsored by four engineering societies the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, the Society of Automotive Engineers and the Society of Naval Architects and Marine Engineers

An international symposium on Algology will be held at the Indian Agricultural Research Institute, Pusa, New Delhi, during December 7–12, under the joint sponsorship of the Indian Council of Agricultural Research and Unesco Main topics which will be discussed are nitrogen-fixing algae, edible algae and their mass culture Further information can be obtained from the Unesco South Asia Science Co-operation Office, 21 Curzon Road, New Delhi, India

Erratum With reference to the communication entitled "A New Method for working up Processing Mixtures containing Anhydrous Aluminium Chloride" (*Nature*, July 11, p 117), Dr T Széll states that a mistake was made in preparing the English translation col 2, line 1, for "20 ml" read "25 ml"

CRYSTAL PHYSICS

THE presentation of the frontier regions of modern physics to an audience with a variable appreciation of scientific and mathematical ideas is, inevitably, a difficult task. None the less, it is one which should not be shunned, unless we are inclined to assume the semantic barrier to be impassable between the pure scientist and the educated public. In the realm of crystal physics with its many facets, the choice of electron-states in crystals as a topic for a discussion by Section A (Physics) of the British Association at the recent meeting in York, did not minimize the difficulties of communication. However, in the first lecture of the session, I attempted to wean the audience from a 'billiard ball' conception of atomic particles and, with little more than de Broglie's hypothesis and the Bragg reflexion law to assist me, to carry them into the mysteries of the energy-band theory of solids. It was not too difficult to begin a discussion of the wave behaviour of electrons in the ordered periodic-field of a crystal lattice, but the going became somewhat harder when the unavoidable introduction of wave vector space occurred. However, the vagaries of the effective electron mass were a little better appreciated by adding the visual aid of a bubble in a spirit-level as an analogy of the positive hole. It was inevitable that such treatment by analogy involved a considerable loss of rigour, but to me it proved to be a valuable exercise in transmitting the important results of the wave mechanical theory of solids without recourse to the mathematical building-materials allowable to the postgraduate seminar room.

The niceties of the band theory for electrons in a perfect crystal were soon disturbed by the reversion to practical situations. The next phase of the lecture dealt with the various crystal imperfections, their effect on electron and hole behaviour and their importance in semiconductor electronics. Again, treating the matter non-rigorously in terms of simple electrostatic forces, brings the problem of donor- and acceptor-levels and types of lattice vacancies into a relatively familiar perspective, and in this instance introduced some of the ideas to be used in the following lecture given by Dr. V. Hesketh.

Many of the important foundations of both experimental and theoretical solid-state physics were laid by the pioneer work of Prof. R. W. Pohl and his research school in Gottingen using the simplest of crystals, the ionic alkali halides. For an audience raised by this stage of the proceedings into the 'thin but bracing air' of wave mechanics, the appearance in a place of honour among beautifully coloured single-crystals of a familiar packet of common table-salt provided a 'down to earth' relief. The theme of Dr. Hesketh's lecture was the alkali halide crystal as a model solid for investigation. Such a claim appears to have been justified by the subsequent discussion. Optical, electrical and other studies provide some of the most certain evidence on the nature of lattice vacancies, single or in aggregation, in solid-state physics to-day. An important feature of this talk was the link which it indicated between such electronic investigations and those concerned with mechanical properties and the role of dislocations in crystals. A connexion with another interest of Section A, magnetism, was in evidence in the paramagnetic-resonance studies of alkali halides. From the general discussion which followed the lecture there was a hint that a 'North eye' was being turned towards dislocations by those, like Prof. L. F. Bates, who follow the motion of magnetic domains. It was a pity that there was no opportunity to demonstrate other links which are rapidly being forged between different branches of solid-state physics and those under examination.

If one might, in conclusion, offer an overall impression of this session in the proceedings of Section A at the York meeting, it is that the conditions of limited time and contact of the meetings have a very stultifying effect on any attempt to make an effective contribution to the communication of new physical concepts to a wider audience of educated people. On this occasion, in spite of the central position occupied by wave-mechanical ideas in the session, it was not a mathematical but a time barrier which blocked the transmission of information. Perhaps this will be borne in mind by the Association in framing a new position for itself as a most important medium for translation as well as transmission of scientific information. From my own limited experience, there is no doubt that courses extended over the year, making use of the facilities offered by extra-mural departments of the universities and similar organizations for further education, would provide a means of digestion for the strong meat of modern physics. As a corollary, the lecturer must bend his rigour of thought to breaking point so that he may admit familiar, though inadequate, analogies as carriers across the semantic obstacles.

G. F. J. GARLICK

SCIENCE BY THE UPPER FORM

AN innovation of Section X (Assembly of Corresponding Societies) of the British Association, whereby a selected panel of young scientists of sixth-form status are able to present short papers on projects with which each has been connected, was continued for the fifth successive year at the York meeting of the Association. This year there were five speakers drawn from Yorkshire schools, each one representing a school team engaged on the acquisition of scientific knowledge in the field, under competent leadership.

Ampleforth College, York, led the way with a paper by M. L. M. Wright on "Physiography and Scenery of the Isle of Eigg", excellently illustrated by colour slides showing the rugged grandeur of an isolated area along the western Scottish coast of only some twelve square miles in extent. Life is hard for the humans living there, and precarious for plant and animal life, dictated by Nature over countless years. The object of the expedition was to study the influence of land formation and climatic conditions on the vegetation of the island, even to an investigation of soil-salt content, which was found to vary considerably at different levels, the highest percentage of salt being at 500 ft., with diminishing amounts down to sea-level. Members of the party collected some 250 species of plant life, but no new records were discovered. Further work in the area is to be undertaken.

In a joint effort, the two speakers who followed (A. N. P. Butland and P. A. Crossley, of St. Peter's School, York) dealt with "Some Scientific Aspects of the River Ouse", the former confining himself to the work of the analytical chemist in connexion with water supply, a work in which he had taken part. Methods adopted in order to detect any possible contamination were described, and the results obtained at various points were given, from which it was apparent that the purity of Ouse water is well safeguarded.

P. A. Crossley concerned himself with 'foaming' in rivers and canals, a natural phenomenon the reason for which was explained, but in these days very much accentuated by the growing use of detergents. The River Don was said to foam much more than the Ouse, the Trent slightly less. Excellent slides were shown to illustrate foaming along these rivers, with graphs to present results of investigations made. Each speaker presented an interesting picture of problems involved.

"The Sedges of Askham Bog" formed the subject of Shaun Firth's paper, excellently illustrated by colour slides. The area investigated is well known to naturalists and close to York. It carries a variety of sedges but, so far as the speaker knew, no systematic study of them had been carried out, interest having ranged only around the rarer species, such as the handsome *Carex appropinquata*. In consequence a group of boys from Bootham School, York, including the speaker, undertook to remedy the omission. The aim was to compile a full list of species and, if possible, "to account for the presence and performance" of the sedges. "We are aware," remarked the speaker, "we have come nowhere near an exhaustive treatment of the subject . . . what made our study of the sedges so enjoyable was the fact that new data came to light with practically every visit to the Bog, to upset our rashly formed theories and force us to observe further and think again." So this, it would seem, is but the introduction to a hitherto neglected subject.

The Bar Convent Grammar School, York, was well represented by Nancy G. Proctor, who, after only eighteen months residence in the City, has absorbed much of its history, having received an introduction by becoming an assistant to Mr. Wenham, history master of St. John's College, York, who is carrying out an excavation under the ægis of the two local archæological societies. Thus Miss Proctor has in a short time been able to increase her knowledge of Roman antiquities, and to add this to her main interest in the archæological field which embraces the works of prehistoric man, in particular the study of promontory forts. Her work in York, even of so short a period, enabled her to trace the City's growth from the time when there was only an "insignificant wooden fort founded on the site in 70 A.D.", and to describe graphically recent investigations which she and members of her school have undertaken.

Another well-known Yorkshire educational establishment supplied both speaker and illustrator for the final paper, "The Seasonal Rhythm and Behaviour of the Birds of Bempton Cliffs", the former in the person of Eileen Burton, and the latter Joanne Littlefair, pupils of the High School for Girls, Bridlington. A bird-watching group visited Bempton at weekly, or twice-weekly, intervals during the year, where along an eight hundred feet stretch of the highest cliff, members studied the seasonal variation of population and the behaviour of six species of nesting seabirds—kittiwake and herring gulls, gannet, guillemot, razorbill and fulmar petrel. The date of the arrival of each species was carefully noted, together with time of egg laying and hatching, and departure. A count made along 200 ft. of the cliff showed the kittiwake to be the commonest species present during May (915), followed by guillemot (543), razorbill (18), fulmar (15), gannet (13), and herring gull (5). Five gannet chicks were hatched and reared in 1959, and as a pair of this species nested on a new ledge there would appear to be hope for an extension of the nesting area, which is the solitary British mainland station, all others being found on islands. A study was made of bird display at various times, methods adopted during time of incubation, and of the feeding of young, which gave Miss Littlefair an opportunity of producing drawings of remarkable quality, which were used to illustrate the talk in wall-chart form.

The Countess of Albemarle, president of Section X, occupied the chair throughout the meeting and in her closing remarks complimented the sixth-formers on their powers of observation, method of presentation and keenness in the respective tasks undertaken, a tribute not only to the young people but to their teachers and leaders as well.

J. A. S. STENDALL

THE MUSEUMS ASSOCIATION

THE sixty-fifth annual conference of the Museums Association was held at Worthing during June 15–19. The proceedings opened with an informal reception in the entirely re-organized Museum and Art Gallery and members were particularly interested in the additional accommodation provided by a new gallery, laboratory, workshop and storage space.

The Conference continued on the following day with an official welcome from the Mayor, Councillor Horace W. Bradley. This meeting, as the others, was held in the spacious and attractive rooms of the Assembly Hall placed at the disposal of the Conference by the Corporation of Worthing.

Dr. W. E. Swinton, British Museum (Natural History), in his presidential address, after outlining the early struggles of the Association, emphasized the value of television and urged both museums and art galleries to use it extensively. It was, he said, the acceptable medium of to-day, 'easy, lazy but direct'. There was abundant evidence that already it had attracted people to visit museums and see the actual objects Dr Swinton emphasized the close relation between science and the arts and stated that whereas thirty years ago they were pleading for more science in museums, which were then chiefly artistic, in this scientific age there was some need for a reversal of the process

The main subject of the Conference was museums and finance, introduced by Lord Rosse, chairman of the Standing Commission on Museums and Art Galleries After recalling the increase of grants from the government which had recently taken place, he emphasized particularly the need for more staff in museums The present shortage of staff was both absolute, because there were not enough qualified people, and comparative, because museum rates of pay were not competitive with comparable professions He felt that museums should not depend too much on the Exchequer but that local authorities and others should do their share Dr Barnett Stross hoped that curators would use the increased grant of £15,000 made available through the Victoria and Albert Museum He felt that the chief needs of the museum movement were for staff of high status with adequate pay, a high standard of conservation and for more realistic purchase grants Sir Hamilton Kerr thought that two stages were necessary, an immediate first aid operation and secondly an expert committee to consider all the problems confronting museums in Britain Sir George Dyson outlined the help that the Carnegie United Kingdom Trust had given to museums over the past thirty years, and Sir Philip Hendy gave some striking facts of the magnitude of the loss suffered by the decay of private patronage since 1914 Sir John Hobhouse outlined the initial steps taken by the newly formed South-West Regional Council, and Mr E M Hutchinson, National Institute of Adult Education, was anxious that local authorities should use to the fullest extent the power to raise money that has already been vested in them

At the close of the discussion resolutions were passed endorsing the recommendations of the Standing Commission relating to tax reliefs on gifts and bequests which should be made applicable to all museums , urging the Standing Commission to form a joint committee with the Museums Association to advise on all professional matters and requesting the Joint Committee on Government Assistance to make a survey of existing conditions in museums and art galleries

In a discussion on the country house and the museum, Mr R Romilly Fedden, secretary of the Historic Buildings Committee of the National Trust, emphasized that the great country house with its contents formed a living organism, and stated that the trust had close relations for expert advice and so on with museums Lord Methuen suggested that the Government might take over some of the empty great houses not too far from London and use them for showing secondary pictures from the National Gallery He also advocated the co-operation of persons with specialized knowledge on local authority committees Mr Philip James, director of Waddesdon Manor, stated that the crux of the problem for using furnished country houses as museums was how to get as many people as possible round the house without destroying its atmosphere as a home

At the annual general meeting Dr W E Swinton was re-elected president, Mr G L Conran was elected secretary and Sir John Rothenstein, editor Mr Charles Carter (Aberdeen), Mr R R Clarke (Norwich), Dr D Dilwyn John (Cardiff) and Dr Mary Woodall (Birmingham) were the newly elected professional councillors and Sir Hamilton Kerr, the Institutional councillor The Earl of Rosse and Dr D B Harden were appointed as additional vice-presidents It was decided to hold the 1960 Conference at Stoke-on-Trent during July 4–9

The concluding day was devoted to field meetings to inspect the historic and archæological wealth of Sussex

THE INTERNATIONAL VETERINARY CONGRESS

THE sixteenth International Veterinary Congress, held in Madrid during May 21–27, was attended by nearly 2,000 members of the veterinary profession from all continents, including official delegates from fifty-two countries and more than one hundred from the United Kingdom The Congress, under the patronage of the members of the Spanish Government, enjoyed the hospitality of the University of Madrid The inaugural general assembly and plenary session meetings took place in the large hall of the new and magnificent building of the Faculty of Law The variety of the papers—about 400 in all—presented during the Congress was very great They were concerned with physiology, nutrition, pathology, public health aspects of animal diseases, food products and veterinary education A balanced review is not practicable here, but a few papers of greater general interest and a few more interesting papers presented by British delegations can be mentioned

As a result of the extensive public interest and concern there has been considerable research and investigation into contamination of the Earth's surface with radioactivity, and its subsequent effect on farm animals, as well as on man and human food of animal origin It has been found that an extremely heavy environmental contamination with fission products would be necessary to produce any significant damage as a result of external exposure of farm animals to β- or γ-rays The radiation exposure of farm animals from grazing in contaminated areas presents no significant hazard to the animals, except perhaps in localities very close to test sites Cows contaminated with radionuclides may become a potential hazard to man through milk, in which they are secreted in more significant quantities than in any other animal food product Papers on this problem were presented by American, German, Dutch and Swedish workers It was generally agreed that in order to be able to appraise continually the effects of fall-out from atomic-weapon tests, and of the discharge into air and water of waste from all plants where nuclear energy is produced and applied, it is necessary to make regular measurements of the radioactivity present in soil, water, air and food

A role of the veterinary profession which has not yet been fully exploited is that concerning public health, and particularly the problem of diseases which are transmissible from animals to man Nearly one hundred diseases are known to be so transmissible, and additional ones are still being found Some of these diseases are transmitted by direct contact of man with live animals, others are transmitted indirectly to people through the consumption of milk, eggs or meat Diseases transmitted from animals to man are defined as 'zoonoses' At present there are many international groups or agencies that are concerned with the control of the zoonotic diseases, but still closer collaboration is necessary between the medical and the veterinary professions in protecting man from zoonoses

One subject which has not before been discussed was that of blood groups of domestic animals In dogs, six distinct blood group factors are recognized

As is the case with newly born babies, it is possible for newly born foals and pigs to die from hæmolytic disease, which is a pathological condition resulting from the union of maternal antibodies with blood-group factors of the red cells of the fœtus

There were several interesting contributions from Great Britain Workers at the Research Institute for Animal Virus Diseases (Pirbright) reported new knowledge on living attenuated vaccines which gives hope of a method of combating foot-and-mouth disease in countries where it is widely spread Foot-and-mouth disease is one of the most serious viral diseases affecting cattle in nearly every country of the world

Workers of the Glasgow Veterinary School have reported successful trials with a vaccine produced against lung-worm infection, which causes great losses in cattle and sheep Immunological basic work concerning parasites was reported by workers from Cambridge They also demonstrated a correlation between immunity and chemotherapy From the Cambridge Veterinary School there also came an important paper classifying respiratory diseases in poultry

A paper on the international standardization of veterinary biological products was delivered by the director of the Veterinary Laboratory of the Ministry of Agriculture and Fisheries

At a charming ceremony during the Congress the president of the Royal College of Veterinary Surgeons presented honorary associateships, awards usually made during the Congress, to five eminent foreign veterinary scientists

The Spanish people were the most hospitable hosts and, in addition to the well-organized scientific site of the Congress, they had prepared a very full programme of evening receptions and other social functions that were greatly enjoyed and appreciated by the members of the Congress At the closing general session of the Congress an invitation conveyed by the German delegation to hold the seventeenth International Congress in Hanover, in order to celebrate there the centenary of the Congress which first started in Germany, was received with acclamation The first International Congress on animal diseases was held in Hamburg in 1863 It was initiated by an English veterinary surgeon, Prof John Gamgee The principal subjects of discussion during the first congress were rinderpest, also called cattle plague, contagious pleuropneumonia of cattle and sheep pox All these diseases ceased to exist in Britain many years ago

The veterinary profession combating many devastating diseases of animals plays an important part, not only in the improvement of the health of animals, but also the health of man M A Soltys

PLANT GROWTH REGULATION

THE fourth International Conference on Plant Growth Regulation was held at the Boyce Thompson Institute for Plant Research, Yonkers, New York, during August 10–14 The Conference was sponsored jointly by the Institute and by the New York Botanical Garden and the Brooklyn Botanic Garden The programme was co-ordinated with the ninth International Botanical Congress held in Montreal, Canada, during August 19–29

The Conference was attended by many invited participants from seventeen countries The United Kingdom was represented by sixteen participants The last conference was held at Wye College (England) in 1955, and before that conferences were held at the University of Wisconsin in 1949 and in Paris under the auspices of the League of Nations in 1937

The first day of the Conference was devoted to naturally occurring growth substances, the second to the gibberellins, the third to the synthetic auxins, and the fourth to other plant growth substances Chairmen of the various sessions included, Prof K V Thimann (Cambridge, Mass), Dr H Burstrom (Lund, Sweden), Dr P W Brian (Welwyn, England), Prof F Lona (Parma, Italy), Prof R L Wain (Wye, England), Dr J Henderson (Tuskegee, Alabama), Dr P E Pilet (Lausanne, Switzerland) and Dr J van Overbeek (Modesta, California) Major evening addresses were given by Dr William J Robbins, director emeritus of the New York Botanical Garden, on the "Expanding Concepts of Plant Growth Regulation", and by Dr James Bonner (California Institute of Technology) on the "Probable Future of 'Auxinology' "

In addition to the scheduled papers ample time was provided for discussion The papers presented and the discussion remarks will be published in book form by the Iowa State College Press in May 1960 Copies will be sent to each participant and will be available to others at nominal cost

Among the new advances reported at the Conference was the isolation of a new class of auxins from Maryland Mammoth tobacco by Dr D G Crosby (Union Carbide Chemicals, South Charleston, West Virginia) and Dr A J Vlitos (Caroni, Ltd , Trinidad, formerly at the Boyce Thompson Institute) About 10 mgm of active chemicals were obtained from a ton of tobacco leaves and growing tips One of the chemicals was identified as 1-docosanol and the other as a long-chain fatty acid not yet fully characterized Bruce Stowe (Harvard) also presented results showing the growth-promoting activity of long-chain aliphatic compounds

Prof T A Bennet-Clark (University of London) reported on the effect of gravity on the distribution of auxins The metabolism of indole auxins in plants was discussed by C H Fawcett, R L Wain and

F. R. Wightman of Wye College. The isolation of a new acid from coconut milk which gives about half the stimulation produced by whole milk was reported by L. H. Weinstein, L. G. Nickell and W. J. Tulecke (Boyce Thompson Institute and Chas. Pfizer).

New concepts on the relation between structure and auxin activity with special reference to the requirements for reactions with necessary binding sites were discussed in separate papers by Prof. K. V. Thimann and Dr. J. van Overbeek. Some physical chemical aspects of synthetic auxins with respect to their mode of action were presented by Prof. V. Freed (Oregon).

This was the first international conference in which the gibberellins were discussed. The Japanese scientists who carried out some of the early work with the gibberellins, T. Hayashi, J. Kato and Yusuke Sumiki, were on hand to present their most recent results. Dr. P. W. Brian (Imperial Chemical Industries, Welwyn), who was a pioneer in directing the attention of the Western world to the Japanese discoveries and who has been very active in this field, reported on new developments from his laboratory. Evidence showing the probable widespread occurrence of gibberellin-like substances in higher plants was presented by C. A. West (University of California).

A feature of the Conference was a memorial dinner to the late P. W. Zimmerman (Boyce Thompson Institute), who with his associate A. E. Hitchcock first tested 2,4-D for its effect on plant growth and development. Other chemicals first tested in his laboratory include indolebutyric acid and 1-naphthaleneacetic acid as well as a variety of substituted derivatives of benzoic acid and various substituted aryloxyacetic acids. P. W. Zimmerman was originally a member of the organizing committee for this Conference but became ill while on a business trip and died in August 1958 at the age of seventy-four.

Financial support for the Conference was given by the Rockefeller Foundation, the National Science Foundation, and fifteen industrial companies interested in agricultural chemicals. George L. McNew, managing director of the Boyce Thompson Institute, was chairman of the Organizing Committee for the Conference. A. J. Vlitos was secretary of the Organizing Committee and chairman of the Programme Committee.

LAWRENCE P. MILLER

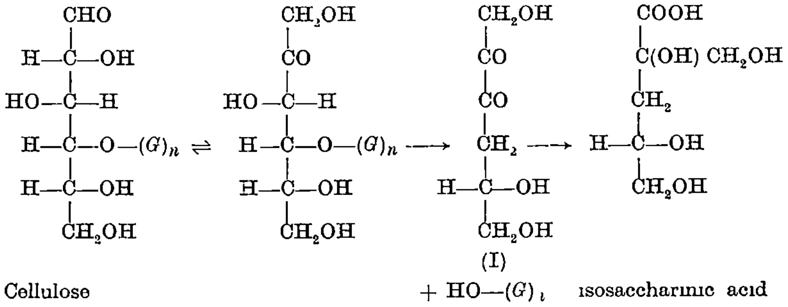
THE BRITISH RAYON RESEARCH ASSOCIATION

OPEN DAYS

THE British Rayon Research Association held the fourth of its annual open days during May 6–8. The total attendance was 900–1,000, a marked increase on the two previous years. Encouraged by the favourable reception last year, the senior chemist and senior physicist again gave short lectures, after lunch on each day, illustrating the relevance of the basic research to current problems in the textile industry. Instead of endeavouring to demonstrate all the work of the Association, a limited number of current researches on topical problems were illustrated rather more fully than usual, and it is believed that this approach may have been, in part at least, responsible for the very high attendance. Two aspects of the work, namely, that on fluid beds' and that on vibration problems in spinning machinery, were not exhibited because of the desire not to interrupt this work at a critical stage of evaluation.

During the past year the research programme of the Association has been critically reviewed particularly in view of the improvements required in the finishing of fabrics constructed from continuous filament viscose and acetate yarns to enable them to compete with resin-treated cotton fabrics. The emphasis on this work has led to a reduction in work on dyeing and on the photo-sensitized oxidation of cellulose and to the termination of the work on the alkaline degradation of cellulose. Concurrently with this, more attention is being given to research on the mechanical properties of textile fibres and to the study of the fine structure of crystalline polymers with the object of defining parameters which will characterize these polymers.

The recent work on the alkaline degradation of cellulose has considerably strengthened the conclusions on the mechanism put forward previously. This mechanism can be summarized in the following reaction sequence.



The intermediate (I) has now been isolated and its structure proved. The alkaline rearrangement of (I) is specifically catalysed by calcium and in lime water an almost theoretical yield of the isosaccharinic acid is obtained. The complex mixture of acids obtained with sodium hydroxide from this intermediate under the hot alkali-refining conditions used in purification of wood pulp is very similar, qualitatively and quantitatively, to that obtained from cellulose under the same conditions.

A considerable part of the resources of the Association are now directed to obtaining an understanding of the structure of textile fibres and attempting to correlate these with their physical, and particularly their mechanical, properties. On the chemical side a systematic study of the effect of known numbers of specific cross-links in cellulose and of substituents in specific regions, namely, crystalline or amorphous, of the cellulose on the mechanical properties has been in progress during the past year. The study of the formation of structure in solution-precipitated polymers is still in progress, but the first system examined, cellulose triacetate in chloroform, has been rejected. Polydecamethylene terephthalate in benzophenone appears to be a more suitable system. Further work on the fine structure of cellulose has established that the microfibrillar structures observed in 'Tenasco' and 'Fortisan' materials are not artefacts but are structural features of these materials. Their significance with regard to the physical properties of these materials has not, however, been established.

The determination of the amount of crystalline material in any crystalline polymer requires special consideration for each case. In the case of the determination of crystallinity in cellulose by X-ray methods the problem is to obtain the shape of the scattering of the amorphous component in which there is considerable orientation, as there is always considerable overlap with the crystalline reflexions. An independent assessment of the shape of the amorphous scattering curve is being made by comparing the information which can be extracted from the X-ray diagrams of highly oriented rayon fibres with the entirely 'amorphous scattering' of freeze-dried cellotetraose, and of ball-milled viscose and native cellulose fibres. (It is well established that ball milling will completely destroy the crystalline structure.) A study, by narrow-beam X-ray and other techniques, of the nature of spherulites in nylon and of their effect on the mechanical properties of this material has been started.

It is difficult to find a new approach to understanding the mechanical behaviour of textile fibres. A textile fibre is essentially a uniaxial solid and most measurements on stress/strain relations are referred to this axis. In many applications, for example the evaluation of the stress system in a yarn, the behaviour of the fibre in a direction perpendicular to this axis may be of equal importance. The mechanical behaviour of an elastic solid with axial symmetry should be completely characterized, within the region of small strains, by five constants. An attempt is being made to measure these constants on polymer films, which are more amenable to such measurements than fibres, and to study their dependence on orientation.

The main emphasis in the Technological Department has been, and will continue to be, on quality. In continuous filament yarns, periodic over-straining caused by inadequate control of tension in winding processes can cause a variety of faults in cloth which often appear markedly only after dyeing. Instruments have been developed for measuring processing tensions and the properties of filament yarns and these are now being marketed. This type of work has absorbed a large amount of technological effort. Certain weft-way types of cloth fault which occur as 'shiring' in continuous filament acetate fabrics and as 'cloudiness' in low construction nylon and 'Terylene' fabrics appear to be due to frictional effects between warp and weft yarns, and consequently, in the weaving research, more emphasis is being placed on these frictional effects.

The number of staff is 266. This total is made up as follows: research staff, 90; laboratory and technical assistants, 77; engineering, drawing office and maintenance staff, 59; library and administrative staff, 31; canteen staff, 9. L. A. WISEMAN

NEW RESEARCH AND PRODUCTION FACILITIES OF CIBA (A.R.L.), LIMITED

NEW research laboratories, a new production plant and sales office extensions of Ciba (A.R.L.), Limited, at Duxford, Cambridge, were formally opened by Dr. R. Kappeli of Ciba, Limited, on May 21 during the celebration of the twenty-fifth anniversary of the establishment of the Company.

The new laboratories are housed in an L-shaped, two-storied building of concrete and brick construction with large plate-glass windows giving the maximum internal illumination in conformity with modern concepts in laboratory construction. The new building, together with the existing research blocks, encloses three sides of lawn and shrub garden. Internally, the use of teak, exposed facing brick and white-painted surfaces accentuates the functional character of the design of the building.

The upper floor of the new building re-houses the research and development department, and the space thus vacated in the original buildings is being used for application and technical service work on wood adhesives. With the additional laboratory space now available in the upper floor of the new block, the group of graduate chemists and their technical assistants in the research and development department are able to explore more thoroughly the current resins marketed by the Company, resins of the epoxy-resorcinol, phenol, urea and melamine types. The work is concerned with the development of resins and hardeners for casting and laminating purposes, for chip-board and wood-glue manufacture, as well as with specialized applications such as adhesives for metal bonding, printed circuits, high-temperature performance and a host of other uses. The extreme variety of the applications to which these classes of resins may be put, and the differing conditions under which they are employed, necessitate a continued and intense search for modified and improved chemical properties and physical forms. An integral part of the investigations undertaken by this unit is the testing of these new and modified materials, and the upper floor of the new building contains a test room well equipped with the necessary machines. This department maintains a close co-ordination with the other departments in the organization concerned with the application of existing products. There is, in addition, a lecture room where frequent colloquia and lectures are given by scientists from the plastics and related industries and by scientists from the academic world.

The ground floor of the new building contains the laboratories of the newly formed fundamental research department, which is devoted to the study of the synthesis of new plastic substances with improved mechanical and electrical properties and with high-temperature and chemical stability. The scope of the work is not restricted to adhesives, but embraces the

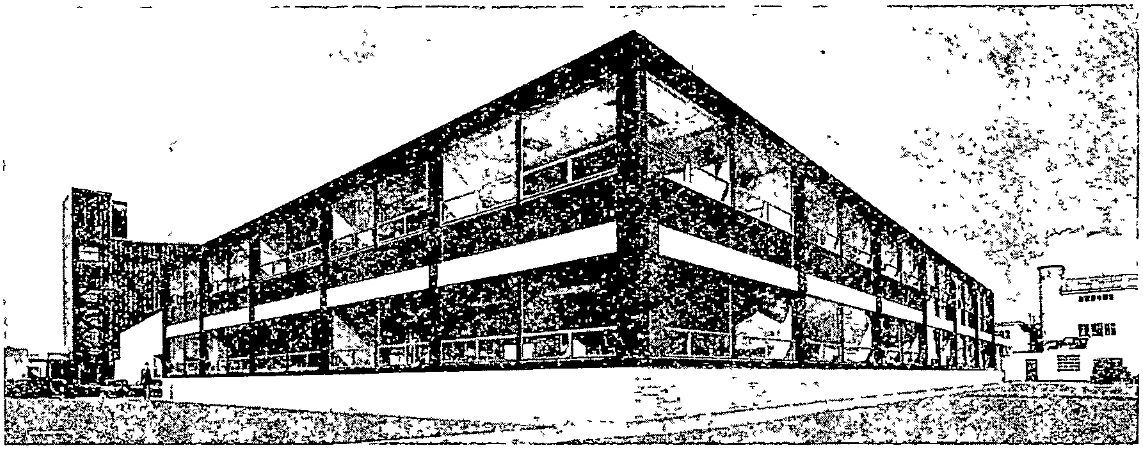


Fig 1 The new Ciba (A R L) research laboratories

possible uses of plastics in many fields The new group is divided into seven teams, each of which is investigating some distinct aspect of the problem, including the synthesis of new raw materials and the pursuit of new condensation and polymerization processes In addition to the usual equipment required for this type of work, the department has an analytical section where particular emphasis is given to infra-red and ultra-violet spectrophotometric and vapour-phase chromatographic analysis The ground floor also contains a central chemical and glassware store and a glass-blowing room, and there is easy access to the library, which has also been expanded to meet the increased requirements

The addition to the research staff at Duxford brings the proportion of those employed in laboratories on research, application, formulation and quality control to twenty per cent of the total staff employed It is clear that the laboratory work can be greatly assisted by the use of modern and automatic equipment and wherever possible this is done, but the quality and quantity of these investigations are still dependent upon the individual skill, knowledge and efforts of the scientist and technician, and every new field entered necessitates an increase in the laboratory staff In contrast to this, the factory has repeatedly been able to increase the volume of production without proportional increases in the labour force employed, and this has been possible only by the continuous introduction of fully automatic processes An outstanding example of this is provided by the new plant, which is now in production, for the manufacture of epoxy resins—resins based upon the condensation of diphenylol propane with epichlorhydrin This plant—although it has a working area of more than 16,000 square feet, several types of reaction vessel and ancillary distillation units with miles of pipe work and more than 500 valves—is maintained by only three men per shift and has more than five times the capacity of the plant it replaces In the new plant the equipment has been designed with the view of minimizing fire hazards, the building itself is of concrete and glass with dished floors to contain spillages, is well ventilated and sited away from the tank farm for the inflammable solvents used in the process, and also from the accompanying control laboratory and switch-house

These new facilities, continuing the programme of expansion of both research and production, demonstrate the rapid growth of the industry and the faith of those who have determined this growth from the modest beginnings of the early 1930's R F WEBB

THE ATOMIC ENERGY AUTHORITY

REPORT FOR 1958–59

THE fifth annual report (pp vii+68+4 plates London H M Stationery Office, 1959 5*s* net) of the Atomic Energy Authority and the last to be issued over Sir Edwin Plowden's signature, who is being succeeded as chairman by Sir Roger Makins on January 1, 1960, covers the year ended March 31, 1959 In that year work started on construction at Windscale of the advanced gas-cooled reactor prototype, the last of the four Calder Hall reactors became critical on December 8, 1958, the first reactor at Chapelcross came into use for generating electricity on February 25, 1959, and the Authority's staff increased from 30,341 to 35,260 No final decision has been reached regarding the transfer from Harwell to Winfrith Heath of the whole of controlled thermonuclear project The terms of the first contract for the supply of fuel for a nuclear power station overseas —the Latina station of Agip Nucleare—were negotiated during the year The Industrial Group has been divided into two groups development and engineering, under Sir William Cook, and production, under Sir Leonard Owen, executive, as well as functional, responsibility has now been restored to the technical members of the Board

The report reviews briefly progress made during the past five years in the application of nuclear energy, during which the first five large-scale nuclear power stations came into operation besides Calder Hall and Chapelcross, the United States 60 MW pressurized water reactor power station at Shippingport, the French 30 MW gas-cooled, graphite-moderated reactor power station at Marcoule and the U S S R

100 MW. graphite-moderated, water-cooled reactor power station in Siberia. In the United Kingdom gas-cooled, graphite-moderated reactors developing towards exit gas temperatures of 550° C. and 750° C. promise to lead to higher efficiency and ratings and a 30 per cent fall in capital costs of nuclear power stations is predicted with the development of the present main types. The application of radioactive isotopes continues to grow, including the use in industry of control instruments based on radioactive isotopes, such as thickness gauges. Total sales of radioisotopes and related products rose from £650,000 to £800,000, the proportion exported remaining at about 60 per cent, to 55 countries. Plans for the extraction of radiocæsium from radioactive waste are being considered in the United Kingdom and the potential output amounts to tens of millions of curies per annum. In raw materials, developments during the year confirmed that the present over-supply of uranium is likely to persist at least until the late 1960's, and the uranium requirements of the free world's current military and civil programmes can now be met by mines already in production, and it seems likely that the forward price of uranium may fall below 8 dollars per pound.

Apart from its first aim of ensuring the successful construction and operation of the nuclear power stations now under construction for the electricity boards, the Authority's reactor development programme comprises extensive work on the development of more advanced types of reactor, the aim of which is to provide progressively cheaper sources of nuclear power, and here the achievement of lower capital costs is a major objective. Efforts are being made to develop ways of using as fuel the plutonium that will gradually become available from the burning of uranium in the early stations. Beyond the natural uranium reactors two stages of development are envisaged. First, the advanced gas-cooled reactor and the water-modulated reactors seek to attain lower capital costs by using slightly enriched fuel. Secondly, the high-temperature gas-cooled reactor being developed at Winfrith Heath as a joint project with other member countries of the European Nuclear Energy Agency, and the fast breeder reactor at Dounreay are characterized by both low capital costs and negligible net fissile fuel consumption. While the present type of gas-cooled, graphite-moderated reactor may command a market overseas where large stations are required, the report points out that considerable advances in nuclear technology will be required before smaller reactors (20–100 MW.) become competitive in normal circumstances. The study of plutonium utilization in reactors continued as well as reactor physics studies in several zero energy reactors.

The report summarizes further research on controlled thermonuclear reactions. The main object of the present experimental programme on *Zeta* and *Sceptre* III is to discover the reason for the excessive loss of energy to the torus walls during the current failure. Work on smaller-scale gas-discharge devices was considerably expanded and some of the formidable technological problems involved in building a thermonuclear reactor are being studied. An Advisory Committee under the chairmanship of the Board Member for Scientific Research was set up in December 1958 to examine and keep under review all aspects of the Authority's research programme on controlled thermonuclear reactions, to advise the Member responsible for research policy on the merits of proposals for new work, and to make recommendations on changes in policy which seem necessary. Other research and development work being carried out by the Research Group, the Industrial Group and the Weapons Group is also briefly summarized. The first ranges from metallurgy, the physics of the solid state to work on particle accelerators. That of the Industrial Group extends far beyond the Group's laboratories, and extra-mural agreements between the Group and universities, research associations and industry now accounts for about a tenth of the Group's annual expenditure on research and development. That of the Weapons Group is illustrated by its examination of soluble chelate complexes of the alkaline earth metal ions and by its measurements of particle size, including use of a centrifugal system to increase the rate of sedimentation with the photo-sedimentometer.

Since its establishment in 1958 under the chairmanship of Sir Douglas Veale, the committee advising the Authority on the supply of specialized health and safety staff has had detailed consultations with many Government departments, hospitals, universities and industry. An interim report to the Authority recommended the initiation of courses in radiobiology and radiological physics at selected universities and provision of studentships if possible for the 1959–60 academic year. This recommendation has been accepted in principle by the Authority and details of the scheme are being worked out in collaboration with the University Grants Committee and the Department of Scientific and Industrial Research. The amount of research and development work contracted out by the Authority continues to increase and more than three hundred professional staff and technical staff from industry have worked with Authority staff during the year.

THE INSTITUTE OF PHYSICS

THE main sections of the thirty-ninth annual report of the Board of the Institute of Physics for 1958 (Pp. 18. London: Institute of Physics, 1959), which was presented to the annual general meeting of the Institute on July 7, deal with membership, examinations, education and publications. During the year, 851 applications for election or transfer to the various grades of membership were received. The total membership increased by 415 to 6,309, with a slight decrease in the number of subscribers (430 compared with 453 in 1957), but with fairly large increases in the associateship and student membership grades. Seven technical colleges which had applied for recognition as institutions possessing courses of study approved for the purpose of the membership regulations were visited by representatives of the membership and examinations committee and six of the applications were approved. In addition, the application by the Borough Polytechnic, London, for recognition of courses on which the Diploma of Technology in physics is awarded was granted. Twenty-six of the eighty candidates who presented themselves for the examination for the graduateship grade of membership were successful , twelve were university graduates and fourteen held the Higher National Certificate in applied physics Forty-one colleges presented 637 candidates for the Ordinary National Certificate in applied physics and twenty colleges 246 candidates for the Higher National Certificate

A joint committee of the Institute and the Physical Society has been set up to inquire into the postgraduate training of physicists and has held discussions with university and industrial physicists The report on "The Teaching of Mathematics to Physicists", which was prepared by a joint committee of the Institute and the Mathematical Association and published originally in 1943, is now being revised The Institute was invited to give its views on the subject of grants to students, and the text of the memorandum submitted by the Board to the governmental committee under the chairmanship of Sir Colin Anderson was published in the January issue of the Institute's *Bulletin*

Satisfaction is expressed in the annual report at the standard and increased circulation of the Institute's older monthly, the *Journal of Scientific Instruments* There was no significant change in the circulation of the other monthly, the *British Journal of Applied Physics*, but both journals suffered a further decline in advertisement revenue New arrangements for selling advertising space to become effective during 1959 and for widening the scope and content of the *British Journal of Applied Physics* have been decided upon A new feature in the 1958 *British Journal of Applied Physics* was the introduction, in the June and October issues, of a 'New Books' section which together contained reviews of 87 books The type size of the *Bulletin* was reduced for the 1958 volume This resulted in a considerable saving in paper, but the 366 text pages, comprising twenty-five articles and fifty-two book reviews, etc , contained more material than the 404 pages of the previous volume

The first annual dinner of the Institute was held on March 26, 1958, at the Savoy Hotel, London, when 267 members and guests were present

The Institute maintains nine branches and seven specialist groups in Great Britain, and two branches overseas, in Australia and Malaya respectively The activities of these sections are briefly described in the annual report, together with extracts from the reports of the Board's representatives and nominees on joint and other committees and organizations The South Australian Division held the sixth Australian instrument exhibition in Adelaide during August 19–22, at the same time as the Adelaide meeting of the Australia and New Zealand Association for the Advancement of Science The second Einstein Memorial Lecture was delivered in October in Adelaide by Prof B J Bok, who took as his subject "Stellar Evolution" The London and Home Counties Branch held a joint meeting in March with the London Section of the Royal Institute of Chemistry on the subject of science and society, and the South-Western Branch joined with the Education Group in a three-day conference in April at the University of Bristol on "Physics in Schools" The Electronics Group and the Midland Branch collaborated in a one-day symposium during April on some applications of solid-state physics in computers and automation, and in September the Group held a two-day conference on "Solid-State Memory and Switching Devices" at University College, London The Non-Destructive Testing Group held its summer meeting in Paris jointly with the Société Française de Métallurgie, when the subject of discussion was "The Utilization of Physical Properties for Studying Relationships between the Constitution Structure and Service Behaviour of Metals"

At the general meeting of the Institute, the following were elected to take office on October 1 *President*, Sir George Thomson , *Vice-President*, Dr J M A Lenihan , *Hon Treasurer*, Dr J Taylor , *Hon Secretary*, Prof F A Vick , and *New Ordinary Members of Council*, Dr V E Cosslett and Mr L Rotherham.

SOME INTERNATIONAL GEOPHYSICAL YEAR ACHIEVEMENTS

THE Royal Society has issued under the above title a small pamphlet constituting an interim statement at the end of the observational phase of the International Geophysical Year The pamphlet contains short notes, arranged under the fifteen subject fields, of statistical details of the work done and of important new deductions so far made from the International Geophysical Year observations Some features of special interest are as follows

Meteorology Ozone observations at the Royal Society base, Halley Bay, Antarctica, show an annual variation in total ozone content with a sharp increase in early summer markedly different from the variation over the Arctic where there are smooth rises and falls about an autumn minimum

Geomagnetism Halley Bay is found to have been most advantageously sited for recording geomagnetic disturbances as it is the only antarctic station just outside the zone of greatest concentration of ionospheric currents In one magnetic storm the range of the fluctuations in horizontal force reached the enormous value of one-sixth the average value of horizontal force

Ionosphere Halley Bay has recorded remarkable features in the diurnal variation of ionospheric electron density in winter The noon value in winter exceeds that at noon in summer and is ten times that at midnight In summer the diurnal range is small with a minimum at midnight These variation types change over suddenly near the equinoxes

Solar activity United States ionospheric observations made by rocket reveal the existence of a powerful flux of solar X-rays at the time of a solar flare This X-ray flux produces the increase in *D*-level ionization which in turn affects long-range radio communications

Cosmic radiation Cosmic ray measurements made by Van Allen with the United States artificial satellites have, as is now well known, revealed the existence of an intense belt of cosmic radiation surrounding the Earth

Oceanography British ships have observed directly the deep ocean currents of the North Atlantic using the 'Swallow' acoustic signalling float which can be set to drift at the required depth One of the currents measured was a southward one below the Gulf Stream

Nuclear radiation The existence of the International Geophysical Year network of nuclear sampling stations in Europe permitted a detailed study to be made of the diffusion of radioactive material released by the Windscale nuclear reactor accident in November 1957

The full prescribed observational work ceased with 1958 and the main task of the present and future is the study of the observations made during the year It is, however planned to continue some observations, apart from those which are part of regular meteorological, etc , services, during 1959 under the title "International Geophysical Co-operation 1959"

The International Council of Scientific Unions has formed special committees to co-ordinate further international work in antarctic research, oceanic research and space research

A further possibility is the making of a magnetic survey on a world-wide scale during the next sunspot minimum for comparison with the magnetic observations made during the maximum period with which the International Geophysical Year was timed to coincide.

RADIO FIELD-STRENGTHS IN THE TROPICS

It is well known that radio-communications conducted by waves which are propagated by reflexion from the ionosphere are critically dependent on the properties of the layers of ionized gas which transmit and attenuate the signals The regular observation of the characteristics of the ionosphere at stations distributed widely over the Earth's surface has made it possible to understand and explain many phenomena which were obscure even ten years ago The International Radio Consultative Committee has, among its other studies, been investigating many technical problems involving the propagation of radio-waves by way of the ionosphere , and of these a most important one is that of tropical broadcasting, for which high-frequency waves are much more effective than medium waves on account of the very high atmospheric noise-level present in most tropical regions Unfortunately the attenuation of the signals in the higher-frequency bands is much greater during the day than is usual at higher latitudes and the reflecting layers are also less stable Thus the problem of providing an adequate signal-to-noise ratio is considerably more difficult in the tropics

The past studies of the International Radio Consultative Committee had shown that the standard methods of computing the field-strength of sky-wave signals were considerably in error at low latitudes , but it also became clear that the additional basic data obtained in recent years provided an explanation of many of the discrepancies disclosed In a report* by W R Piggott, recently published by the Department of Scientific and Industrial Research, Radio Research Station, this subject is reviewed with the aid of an analysis of the problem of identifying the most effective type of ionospheric reflexion for particular circumstances This report shows that some of the difficulties in interpreting the results of field-strength measurements at low latitudes have been due to changes in the dominant mode of ionospheric propagation, and the consequent variations in the attenuation of the waves, and the angle of elevation at which they arrive at the receiver The rate of advance of knowledge of this subject depends on the continual interplay of practical observations with theory , and it is hoped that the publication of this report, together with its presentation at the Plenary Assembly of the International Radio Consultative Committee recently held in Los Angeles, will encourage radio research workers in low latitudes to investigate their wave-propagation phenomena in more detail

BRITISH BOOKS AND FOREIGN MARKETS

In reply to a series of questions in the House of Commons on June 22 regarding the supply of British books and periodicals overseas, Dr C Hill, the Chancellor of the Duchy of Lancaster, made a long statement which was circulated in Hansard The study of ways and means of increasing the flow of British books and periodicals overseas has now been completed Recognizing that British books can do much to help other peoples to understand our way of life and that they make a very real contribution to the life and thought of other nations, the statement points out that there is an ever-increasing demand for reading-matter in English, and we must do more to promote the flow of British reading-matter overseas Other countries are already producing large amounts of well-produced attractive literature which is easy to read and inexpensive and is aimed particularly at Asian and African countries Although in 1958 exports totalled nearly £24 million, or almost two-fifths of the turnover of the United Kingdom book trade, several countries impose, for currency reasons, substantial restrictions on imports of British books and periodicals and our exporters cannot make further headway in these markets Low individual incomes in many countries and the lack of effective library and other distribution systems are also major difficulties

Accordingly, the Government has decided to take five steps to promote the export of British books and periodicals

(1) To enter into negotiations with various countries with the aim of establishing schemes operating

broadly on the lines of the British book export schemes which were established during the War and in the immediate post-War period

(ii) To promote the production of low-priced editions of a range of British books for sale in certain countries where there is a large unsatisfied demand for such books This will call for substantial Government expenditure

(iii) To authorize a further expansion of the British Council's library services in several centres and of the Council's resources for presentations of books and periodicals abroad on which the Council this year expects to spend in all about £650,000

(iv) To assist, through the British Council, in the development of library systems in some Colonial territories, including the establishment of central libraries, regional branches, book vans and book boxes

(v) To co-operate with publishers in measures to enable them to increase their circulations in some of the more difficult markets overseas

Parliamentary approval for the expenditure involved will be sought at the earliest convenient opportunity and it will be necessary to proceed in consultation with the Governments of the Commonwealth and foreign countries concerned, and Dr Hill promised to inform Parliament as soon as agreements had been concluded In reply to a further question Dr Hill said that the increase in the British Council's resources would be concentrated on scientific and technical books, but the schemes to be negotiated with countries where import restrictions prevent the flow would cover a wide range of books He hoped that in the next year it would be possible to reach up to 2 million copies of low-priced books This would be done in association with the publishers who own the copyright of the books concerned and would involve Government aid to narrow the gap between the economic price and what could be paid in the countries of reception Replying to specific questions, Dr Hill said that British book exports in 1958 to India were recorded in the Trade and Navigation Accounts as £424,427, to Pakistan £39,950, to Ceylon £15,732 and to Israel £9,473 Dr Hill estimated the increased expenditure as about £500,000 next year.

FORESTRY IN NEW ZEALAND

THE annual report of the director of forestry of New Zealand for the year ending March 31, 1958, is of more than usual interest in that it includes a general historical review of both departmental activities and general land use and administration, covering the past forty years The need for such a review had been particularly stressed by the Minister of Forests (Mr Tirikatene) and was prompted also by the meeting of the British Commonwealth Forestry Conference which had been held in the country during September–October 1957 The Minister himself (a Maori) contributes a prologue recognizing that the great forestry effort involved in creating a very large acreage of exotic softwood plantations, mainly of *Pinus radiata* from California, by the quick production of an alternative supply of essential timber, has saved a large remnant of the native forest at the same time he calls for much greater attention to the maintenance of this forest, especially for its value in protecting soil and conserving water The disastrous consequences of the denudation of the hillsides in the form of soil erosion and then extensive floods are all too widespread and serious to be ignored any longer Quoting two specific examples, he suggests that the Urewera indigenous forests in North Island, largely in Maori ownership, might in the national interest have to be managed primarily for soil stabilization and water retention, not timber, while in the hills behind Canterbury, all land more than 3,000 ft high might have to be taken out of pastoral use, even the city itself is now threatened by flood devastation It must be encouraging to the Forest Service to have this official backing, which is combined with full recognition of the essential need of stable finance for the necessary research work and for remedial measures

The visit of the Commonwealth Conference stimulated the preparation of a number of research papers covering many of the lines of activity which have called for special attention of recent years Some of the topics dealt with are also currently prominent elsewhere, especially where softwood plantations play an important part, such are problems in genetics, and the relation between sylvicultural treatment and market requirements in respect of both dimensions and quality (whether for timber or pulp) There are also problems of the later management and regeneration of the plantations, as in the United Kingdom During recent years, a good deal of thought has been given to the management and regeneration of the native forests, both those with important softwoods, notably kauri (*Agathis australis*) and the various species of *Podocarpus*, and the 'beech' forests (*Nothofagus* spp) Encouraging progress is being made but rates of development are, of course, very slow compared with those of the introduced conifers, and, as already noted, these forests have other functions to fill as well as timber production

The Commonwealth Conference appointed a special committee to report on New Zealand forestry In the report, as Resolution 6 of the Conference, alarm is expressed at the poor condition of the remaining indigenous forest as a result of past exploitation, and expansion of research programmes is urged, the publication of Volume 1 of the "National Forest Survey of New Zealand" for these forests in 1953 is commended, as is also the extension of the survey to protection forests

It may be noted that damage to the native forests by introduced animals, above all red deer and opossums but also wild goats and pigs, is still a really serious problem, so much so that there is a special division to deal with 'noxious animals' To reinforce shooting operations in the natural forests, bounties are paid for animals killed outside The numbers killed in the year in what do not claim to be more than 'holding' operations are striking, namely, 55,000 deer, 28,000 goats, 4,000 pigs and 4,000 chamois by the State alone The opossums are mostly killed outside the reserves, 900,000 in the year (after more than a million in 1956)

The control of noxious animals was only taken over by the Forest Service two years ago and there is a strong case for a similar taking over of soil conservation and river control, so that the troubles can be dealt with at their source instead of trying to remedy them after the damage has already been done, as is currently happening

There is still a big exotic planting programme, 8,744 acres having been added in the past year. The major features are the clearing and replanting of former failures, notably those with *Pinus scopulorum*, a mistaken choice, and the extension of the work on to the coastal sands of the North Island which are unsuitable for agriculture, where the plantations will not only be productive in themselves but will also protect the fields from sand encroachment.

The annual report of the New Zealand Forest Research Institute for the same year ending March 31 (Pp. 100. Wellington: Government Printers, 1958) amplifies many of the points referred to above, and it also looks back over its first decade of work, expressing the feeling that it is now well established as a fully co-ordinated research centre, with an advisory committee representing both industry and all related research organizations. The graduate staff now numbers nearly fifty with a comparable number of technicians, but the Commonwealth Conference thought that there is still need for an increase on both the forestry and forest products sides.

H. G. CHAMPION

UBIQUINONE AND VITAMIN E

By DR. THOMAS MOORE

Dunn Nutritional Laboratory, University of Cambridge and Medical Research Council

SOME time ago we noticed[1] the presence in the livers of rats of an alkali-labile substance with a sharp absorption band at 275 mμ. For the purpose of studying the distribution of vitamin E in the body the rats had been given diets which were only barely sufficient in vitamin A. This restriction was intended to eliminate the strong spectroscopic absorption of vitamin A at 328 mμ, and so allow the measurement of vitamin E by its weaker absorption[2] at 294 μm. In the body-fat of rats given wheat germ, rich in vitamin E, the presence of this vitamin was readily detected. In the liver, however, the detection of vitamin E was made difficult by the absorption at 275 mμ which has already been mentioned.

We were reminded[3] of these early observations by reports by Lowe, Morton and Harrison[4] of fractions from the livers of rats deficient in vitamin A which adsorbed at 275 mμ, with other maxima at 233, 283 and 332 mμ. These workers thought, at the time, that abnormal steroid products had been formed as the result of the avitaminosis. We confirmed the presence of a band near 275 mμ in liver extracts of rats deficient in vitamin A. Saponification of the liver-fat with hot alcoholic potash caused the band to disappear, but it survived the same treatment when applied to the liver tissues. Presumably the tissues protected an unstable substance against oxidation. The band disappeared from solutions which were treated with 85 per cent sulphuric acid, were aerated, or stored for 37 days at − 10° C.; it survived treatment with digitonin. Sterol-free extracts of unsaponifiable matter, made by the direct saponification of the tissues, were neither fluorescent under ultra-violet irradiation nor chromogenic in the antimony trichloride test. By paper chromatography evidence was obtained of the presence of two substances with absorption maxima at 275 mμ. One had a single sharp band at this position, but the other had also an inflexion at 330 mμ. Both substances were faintly yellow, but had no selective absorption in the visible. Bands at 272–275 mμ were also found in liver extracts from rats which had been cured of avitaminosis A, from normal sexually immature rats, and from a normal pig and guinea pig.

The existence of two substances, with their main absorption maxima at the positions observed by us[3], was also reported by Heaton, Lowe and Morton[5]. The names substance *A* and substance *C* were given. Both had their absorption maxima at 275 mμ, but *C* differed from *A* in having a sharper inflexion at 330 mμ; both substances *A* and *C* were found in the livers of normal animals, although the concentration of substance *C* in the liver of normal rats was much lower than in the livers of rats suffering from vitamin A deficiency. *A* and *C* were also found in various tissues other than liver, and in different species[5,6].

Further extensive investigations by the Liverpool school, reviewed by Morton[7], have led to the isolation of substance *A*. It is not a sterol product, as first expected, but a derivative of 1-methyl-5,6,dimethoxy *p*-benzoquinone. In view of its wide distribution the name ubiquinone was given. The striking feature of its structure is a long unsaturated side-chain, comprising 50 carbon atoms, attached at the 2 position. Similar conclusions as to the constitution of ubiquinone, otherwise known as *Q* 275 [8] or mitoquinone[9], have been reached in America[10]. According to Lester, Crane and Hatefi[11], ubiquinone is only one of a whole new series of quinones, which vary in the nature of the side-chain.

Some workers[12] consider that ubiquinone plays an important part in tissue oxidations. Others[13] have ascribed a similar role to vitamin E. The roles of both vitamin E and ubiquinone in heart muscle preparations have been reviewed by Slater[14], who has suggested that the question whether there is a chemical or functional relationship between the two substances deserves investigation.

Vitamin E and ubiquinone have common properties in being soluble in fats, in being capable of undergoing reversible oxidation or reduction, and in being unstable to alkaline saponification in the presence of oxygen. They differ in vitamin E being found in animal tissues mainly in the reduced state, whereas ubiquinone is mainly in the oxidized state. Regarding their distribution, ubiquinone has been found mainly in mitochondria, whereas vitamin E can be stored in the body-fat[1]. Since vitamin E is a potent anti-oxidant, it might possibly intervene in the metabolism of ubiquinone by protecting it against irreversible and destructive oxidation.

It was of interest, therefore, to inquire into the effect of vitamin E deficiency on the concentration of ubiquinone in the tissues. The preliminary evidence on this point[1] may now be re-examined on the basis of pure ubiquinone having E (1 per cent, 1 cm.)[15] at 272 mμ = 167. A rough estimate of the concentration of ubiquinone, without allowance for the possible presence of substantial amounts of substance *C*, may be calculated from the difference

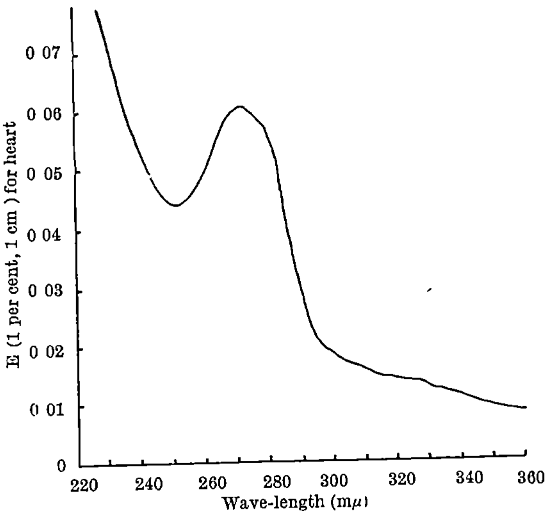

Fig 1 Absorption spectrum of an extract of the heart of a rat, deficient in vitamin E The presence of ubiquinone is indicated by the maximum at 275 mμ

between the absorption of the extracts at 275 mμ before and after saponification On this basis the liver of a rat which had been kept for four months on a diet deficient in vitamin E contained about 320 μgm of ubiquinone per gm The liver of a rat which had been kept for two or four months on a diet containing 60 per cent of wheat germ, and therefore rich in vitamin E, showed little difference from that of the deficient animal with 270 and 290 μgm per gm of ubiquinone, respectively

These early values for liver have now been supplemented by results, obtained by the co-operation of Dr I M Sharman and Miss Margaret Smith, on rat's hearts The hearts were taken from piebald males, which had received a diet deficient in vitamin E for eight months The severity of the deficiency was demonstrated in all the animals by the degeneration of their testes Since vitamin A does not accumulate in the heart in more than traces, it was unnecessary to restrict the intake of this vitamin, as is advisable when the liver is to be examined for ubiquinone The hearts were digested in alcoholic potash in the presence of pyrogallol as an additional protective agent[16], and the fraction containing ubiquinone was extracted with ether In spectrophotometric examination the maximum at 275 mμ seemed sharp enough to provide a rough indication of ubiquinone contents without further refinement of the extract A typical curve is shown in Fig 1, from which it will be seen that there was no inflexion at 330 mμ, the position indicative of substance *C* For four deficient rats, ubiquinone concentrations of 277–365, mean 338 μgm per gm of heart, were found Four similar rats, which had been given the same diet but with adequate doses of *dl*-α-tocopheryl acetate, had ubiquinone concentrations of 303–371, mean 331 μgm per gm of heart No evidence of an absorption maximum at 294 mμ, indicative of vitamin E, could be seen in heart extracts from either the rats deficient or adequate in vitamin E This was in line with our early experience[1] that the detection of vitamin E in liver extracts is prevented by ubiquinone even when vitamin A is absent

In these investigations, therefore, there was no indication of any relationship between the ubiquinone contents of the tissues and the vitamin E status Morton[7] has reached the same conclusion, but his evidence has not yet been published

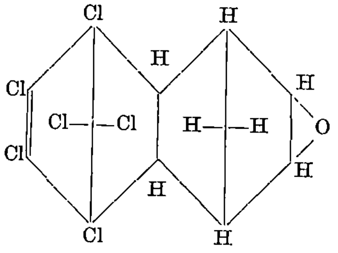
MECHANISMS OF RESISTANCE OF ADULT HOUSEFLIES TO THE INSECTICIDE DIELDRIN

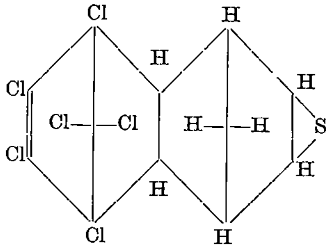
By F P. W WINTERINGHAM and A HARRISON
Pest Infestation Laboratory, Slough, Bucks

PENDING the successful syntheses[1] at this Laboratory of the insecticides labelled with carbon-14, the absorption, metabolism and excretion of the sulphur analogue labelled with sulphur-35 (II) of dieldrin (I) by dieldrin-resistant (*R*) and susceptible (*S*) adult houseflies (*Musca domestica*) have been studied Adults of the *S*-strain were from the normal laboratory stock Pupæ of the *R*-strain were obtained through the kindness of Dr J R Busvine and originally collected at Omdurman (Sudan)[2] The first generation of *R*-adults at this Laboratory (March 1957) displayed little resistance to topically applied I but after breeding through 6 generations on larval food containing I at a final concentration of 150 p p m the adults were highly resistant to either I or II when applied topically in acetone There was evidence of only a slight initial loss in resistance in adult *R*-flies after breeding through a further 19 generations in the absence of I

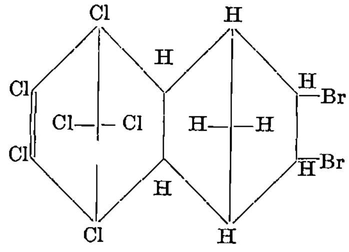
The radioactive insecticide (II) was applied topically to the dorsal thorax in 2 μl acetone to individual *R*- and *S*-adult flies while under mild *cyclo*propane anæsthesia and the flies kept in fresh air at 25° C without food or water for 3 hr Signs of poisoning appeared in *S*-flies alone towards the end of this period The flies were confined in groups of 10 or 20 to 1-in strips



(I)



(II)



(III)

of Whatman No 1 paper by means of shallow glass-covered cages so that almost all the excreta and vomit were collected on the paper Control groups were similarly set up in which the ani had been sealed to prevent excretion The difference between the radioactivities recovered on the normal and control papers thus represented net excretion , radioactivity of the control paper represented contamination by mechanical contact with the flies, vomit, etc After 3 hr the insects were anæsthetized and rinsed in acetone to remove unabsorbed insecticide Heads, thoraxes and abdomens were separately homogenized and extracted with acetone Acetone-insoluble metabolites were assayed in the extracted tissues Unchanged insecticide and metabolites were determined by radio-paper chromatographic techniques Only unchanged insecticide was recovered from flies which had been killed by heat before the experiment except for a small fraction present in all extracts which behaved as the sulphone of II under the conditions of paper chromatography used and is believed to arise largely through atmospheric oxidation The results of experiments in which 2 μgm of labelled II was applied to adult flies (50 males + 50 females) are collected in Table 1 This dose was lethal to all *S*-flies but innocuous with respect to *R*-flies The results were determined as ^{35}S-radioactivity, corrected for decay, self-absorption, etc , and expressed as a percentage of the dose applied

After 3 hr all the *S*-flies became prostrate and ceased to excrete , but metabolism of the absorbed insecticide continued for several hours, the metabolites accumulating mainly in the abdomen Resistant flies, on the other hand, continued to excrete their metabolites Thus, sealing of the anus had little effect on the accumulation of metabolites in the abdomen of the *S*-fly but a marked effect on that of the *R*-fly as shown graphically in Fig 1

Table 1 FATE OF (^{35}S) SULPHUR ANALOGUE OF DIELDRIN 3 HR AFTER TOPICAL APPLICATION TO DIELDRIN RESISTANT (*R*) AND SUSCEPTIBLE (*S*) ADULT HOUSEFLIES AT A DOSE OF 2 μGM PER INSECT

	S-strain Per cent applied dose	*R*-strain Per cent applied dose
Lost by volatility of insecticide* during treatment, manipulation, etc	34 3	27 2

Acetone-insoluble metabolites in thorax	1 0	0 7
Acetone-insoluble metabolites in abdomen	5 2	4 3
Unchanged insecticide excreted	3 4	2 7
Water-soluble metabolites excreted†	0 3	0 8
Water-insoluble metabolites excreted	0 5	0 9
Unchanged insecticide lost by mechanical contact and vomit	2 1	2 2
	100	100
Total effective detoxication stored metabolites + excreted metabolites and insecticide as per cent dose absorbed	38	35

* Determined by difference, but in one experiment a loss to the air of the insect chamber was demonstrated radiometrically

† Not sulphate

Some experiments were made with a non-insecticidal compound labelled with bromium-82 (III) so that metabolism and excretion of a related compound by *S*- and *R*-flies could be compared in the absence of toxic effects These experiments indicated that over a 24-hr period both strains excreted similar proportions of the unchanged compound together with small similar proportions of water-soluble metabolites

These experiments strongly suggest that resistance of the *R*-flies to dieldrin is not due to lack of cuticular penetration, or to a gross difference in the rates of excretion or metabolism of the insecticide by the *S*- and *R*-insects An efficient defensive mechanism is certainly operating in the *R*-insect during the first 3 hr because, towards the end of this period, the *S*-insect rapidly succumbed and there were signs of an irreversible lesion such as an exhaustive burst of respiration and fall of tissue α-glycerophosphate Other experiments at different dosages (0 37–5 μgm insecticide/insect), or of different duration (0 3–24 hr),

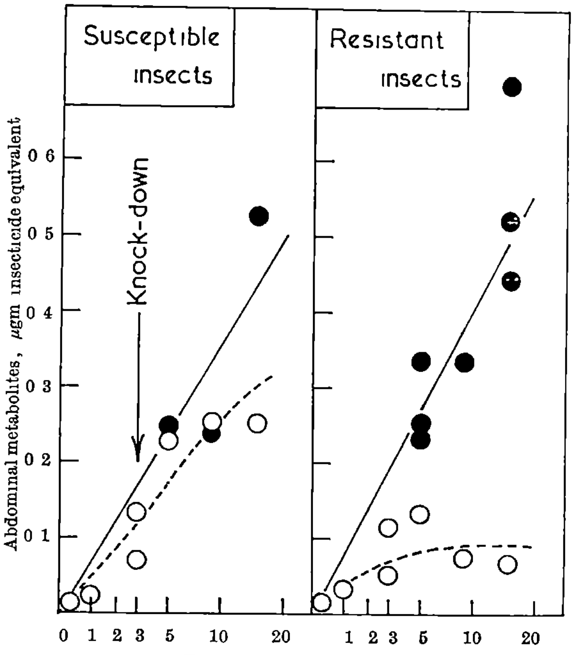

Fig 1 Accumulation of sulphur-35 metabolites in the abdomens of adult houseflies exposed to 2 μgm dieldrin-^{35}S analogue ○ - - - ○, excretion possible , ●—●, anus sealed, excretion not possible

or with an independent pair of S- and R-strains have led to the same conclusions

By chemical assay March, Metcalf and Baich (Metcalf, R L , personal communication) were unable to find any difference in cuticular penetration or in the apparent disappearance of absorbed dieldrin from their susceptible and resistant houseflies

The protective mechanism may be confined to particular sites, which involve only a small fraction of the absorbed insecticide For example, Yamasaki and Narahashi[3] found some evidence of a lowered sensitivity to dieldrin of the exposed thoracic ganglion of resistant houseflies which did not involve detoxication in other tissues

These experiments are part of an investigation into the mechanisms of dieldrin resistance in Diptera, supported in part by a research grant from the World Health Organization Full details will be published elsewhere

MOLECULAR SHAPE AND THE PHYSICAL PROPERTIES OF MUCIN

By R A. GIBBONS

National Institute for Research in Dairying, Shinfield, Reading

EPITHELIAL mucin is an important secretion having somewhat unusual physical properties, and it has been shown, in two instances, that the materials responsible for these physical properties are so-called 'neutral' mucoids of the blood group substance type[1] Little is known at present of the molecular form of this class of compound , but evidence has been obtained, mainly from flow-birefringence measurements, indicating that these particular mucoids are molecules of the 'random-coil' type[1] It is of interest to re-examine some earlier work on mucoids of this type in the light of this result In particular, the physico-chemical data on the human blood group mucoids of Morgan and co-workers[2] may be re-considered These specimens were isolated from the same source and carefully purified using similar mild techniques, they differ in molecular weight over the range 2 6 × 10^5 to 1 8 × 10^6, but the chemical differences between them are, from the physico-chemical point of view, minor They may thus be taken to represent a homologous polymer series, something difficult to find elsewhere in the field of mucoid chemistry

Of the relationships known to exist between members of a homologous polymer series of random coils, two may be tested using published physico-chemical data The relationship between sedimentation coefficient at infinite dilution, s_0, and M, the molecular weight, should be of the form $s_0 = A + B\sqrt{M}$, where A and B are constants[3] Further, $\left[\frac{\mathrm{d}(1/s)}{\mathrm{d}c}\right]_{c \to 0}$ (c = concentration) should be independent of M as the following considerations will show Burger's equation for the variation of sedimentation rate of suspension of spheres with dilution has been found applicable to a number of polymers at low concentrations[4], as is reasonable in that the random coil molecule in translation approximates well to an impermeable sphere[3], due to the large amount of solvent it entrains within it

Taking $s = \frac{s_0}{1 + \Lambda\, nv}$, where Λ is a constant[4], n is the number of molecules per unit volume, and writing $\frac{Nc}{M}$ for n, where N is Avogadro's number, we have $\frac{1}{s} = \frac{1}{s_0} + \frac{\Lambda N c v}{s_0 M}$, so that $\frac{\mathrm{d}(1/s)}{\mathrm{d}c} = \frac{\Lambda N v}{s_0 M}$ Remembering that $s_0 = \frac{M(1 - \bar{v}\rho)}{N 6\pi\eta_0 a}$, and $v = \frac{4}{3}\pi a^3$, where a is the effective radius of the molecule and the other symbols have their usual significance, we may write the differential $\frac{8\,\Lambda\, N^2\pi^2\eta_0 a^4}{M^2\,(1 - \bar{v}\rho)}$. For a homologous polymer series in the same solvent, M is proportional to the square of any linear dimension of the molecule[5] Hence $\frac{a^4}{M^2}$ is constant in these conditions

The values of $s^0_{20,w}$ and $\frac{\mathrm{d}(1/s)}{\mathrm{d}c}$ given in Table 1 were obtained by extrapolation of the graph of $\frac{1}{s}$ against c to $c = 0$ A linear extrapolation was made although in the case of the first and third specimens quoted linearity is not good The values of $\frac{\mathrm{d}(1/s)}{\mathrm{d}c}$ given in Table 1 are thus averages between $c = 0$ and $c = 1$ per cent , furthermore, different degrees of polydispersity in the samples will cause some variation in the slopes observed, so that there is reasonable agreement with theory Linearity between s_0 and $\sqrt{M}$ is good The conclusion that these mucoids are of the random-coil form may be drawn with some confidence

It is interesting to note that the physical properties of mucin may be reasonably interpreted on the basis

Table 1 SEDIMENTATION COEFFICIENTS AND MOLECULAR WEIGHTS OF MUCOIDS

$s^0_{20,w} \times 10^{13}$	M	$\sqrt{M}$	$\frac{\mathrm{d}(1/s)}{\mathrm{d}c} \times 10^{-13}$*

* c in gm /100 ml

Data from Kekwick (ref 2) and Caspery (ref 2) of what is already known of the properties of random coil molecules Epithelial mucin frequently gives rise to two phases in water, a rather dilute swollen gel phase and an aqueous phase which is almost pure water The gel phase displays visco-elastic or plasto-elastic rheological properties and may also show the Weissenberg effect These properties are entirely consistent with those of a random coil polymer below its Θ-point The gel phase may be dispersed to give a viscous solution by raising the pH, or the temperature, or by adding to the solvent a third component (for example, urea, calcium ions) Again, this behaviour is to be expected of a random-coil polymer if it contains potentially negatively charged groups, and if the solute-solvent interaction parameter[5] is increased by the addition of the third component

The physical properties of solutions of random-coil polymers have been extensively studied, and a good deal of the theoretical thermodynamic background is available , a full exposition is given by Flory[5] A consideration of this work may be of some value in the interpretation of the biochemistry and biophysics of mucous secretions, and attention is invited to three points (1) The molecular weights of mucoids may be determined from sedimentation coefficients and intrinsic viscosities, the latter being a more readily and more precisely determinable parameter than the more usual diffusion constant Moreover, axial ratio as usually evaluated from the frictional ratio is not meaningful with respect to this type of molecule (2) Where mucoids are modified by chemical treatment or by enzymes and a fall in viscosity is observed, this has usually been interpreted as a depolymerization Some caution is required here, since the change in viscosity may be largely due to chemical changes which alter the thermodynamic interaction parameter, or the related molecular expansion factor, and not necessarily to depolymerization (3) The degree to which the molecule is coiled up (that is, the molecular expansion factor) may effect the availability of antigenic sites on a mucoid molecule to antibody, and may be a factor concerned in its immunological reactivity

This work is part of a programme supported by the Population Council, Inc , Rockefeller Institute, New York

AN ASSOCIATION BETWEEN ABO BLOOD GROUPS AND FERTILITY IN A NORMAL AMERICAN POPULATION

By Dr. T. EDWARD REED
Department of Human Genetics, University of Michigan
AND
Dr J H AHRONHEIM
W. A. Foote Memorial Hospital, Jackson, Michigan

THE possibility of fertility differences associated with ABO blood group phenotype has been investigated in married couples in two populations[1,2], using couples unselected with respect to their fertility In 161 white American couples who had completed their families, fertility differences associated with blood groups could not be demonstrated[1] Such differences were found, however, in 1,429 Japanese couples of varying ages[2] A study of the fertility of 1,290 married English men and 1,319 married English women, age fifty years or more, failed to demonstrate an association between individual fertility and ABO blood group[3] We wish to record here observations on 558 white American couples in which fertility differences associated with blood groups do appear to be present

The present data were obtained from an investigation carried out for other purposes In the winter of 1950–51 a mass blood grouping (ABO and *Rh*) programme was carried out in Jackson County, Michigan, on 48,652 individuals by the Michigan Civil Defense[4] 72 per cent of the inhabitants of the city of Jackson (pop 51,088 in 1950) were included in this programme Blood from venepuncture was used and the ABO phenotypes were determined both by cell typing and back-typing of isoagglutinins In addition to ABO and *Rh* status, the name, address and religion were recorded for each individual For 64 per cent of the individuals, the date of birth was also noted , about 50 per cent of these persons were less than 15 years of age Family relationship was not recorded Afterwards, for the present analysis, the information on each individual was transferred to an I B M punch card and these cards were sorted by exact street address Whenever two or more persons having the same surname, street number, and street name in the city of Jackson were found, the city directory was consulted to determine if two of the persons were husband and wife If this was the case and there were other individuals of the same surname at this address, age relationships were examined to see whether these individuals could reasonably be children of the husband and wife Unless there was some definite indication, such as appropriate dates of birth, that this was so, the individual was not counted as a child of the couple Three thousand six hundred and twenty-eight 'families' were found Home interviews of 90 randomly chosen couples were made in the spring of 1958 to test whether these 'families' had been 'constructed' successfully The true number of children born by the time of the blood grouping to 53 couples in which the wife was born in 1910 or later was 79 , the number in our 'families' was 66, of whom 62 were correctly assigned, 1 was adopted, and 3 (all in one Negro family) were born out of wedlock but probably were the biological children of the couple For couples whose wives are in this age-range it is therefore probable that about 80 per cent of the actual children are correctly recorded

Table 1 DISTRIBUTION OF 558 MATINGS BY ABO BLOOD GROUP* AND NUMBER OF CHILDREN—WHITE PROTESTANT COUPLES IN WHICH THE WIFE IS 30-39 YEARS OF AGE

This communication reports on 558 couples which are Protestant, non-Slavic in surname, non-residents of the well-defined Negro district, and in which the wife is in the 30–39 year age group The first three restrictions reduce racial heterogeneity and ensure that, in the absence of natural selection, the probability that a given child was included in this study should be practically independent of the blood groups of his parents Various sources of error should also be independent of parental blood group (blood groups were not used in matching children and parents) The number of children recorded should therefore be proportional to the true number and valid comparisons of relative fertility can be made Women of completed fertility would ordinarily be preferable, but in these observations, they appear to be less fertile because their children often no longer reside in the parental home and so are missed

The distribution of couples by blood group and number of recorded children is given in Table 1 Analysis of variance of number of children, after suitable transformation of variable to correct for the non-normal distribution, can be used to test whether blood groups are related to fertility[1] This analysis is presented in Table 2 The transformation used $y = \sqrt{x + 1}$, where x is the number of children gives a distribution which does not differ significantly from the normal Bartlett's test indicates that the variances of y in the various matings are homogeneous Since all possible matings involving AB individuals are not represented, the analysis of variance was made on the 518 matings distributed among the 9 mating types involving A, B and O individuals

Table 2 ANALYSIS OF VARIANCE OF $y^* = \sqrt{x + 1}$, WHERE x IS NUMBER OF CHILDREN

Matings including AB individuals are omitted

Item	Degrees of freedom	Sums of squares	Mean squares	F ratio	P
Males	2	0 2819	0 1410	0 910	> 0 25
Females	2	0 3061	0 1531	0 988	> 0 25
Interaction	4	2 2658†	0 5665	3 657	< 0 01
Between matings	8	2 8538	0 3567	2 303	< 0 025
Within matings	509	78 8653	0 1549	—	—
Total	517	81 7191	0 1581	—	—

* Analysis of variance of x is similar, giving an interaction F of 3 242, $P < 0$ 025

† Obtained by subtraction The value obtained by fitting constants is 2 2908, giving an interaction F of 3 697

It is seen that the two main effects, males and females, are not significant, but that interaction (between males and females) is significant at the 1 per cent level This suggests that the significant difference between mating types in fertility is a property of the serological mating type and is not due to blood group differences among males or among females The biological interpretation of this result is not obvious, however, since (Table 1) the serologically incompatible matings (those in which the husband has an agglutinogen lacking in the wife) are significantly more fertile than the compatible matings ($P < 0$ 025, 2 tail test) In the Japanese study[2] the reverse was true, suggesting that ABO incompatibility is important in Japan, but in the previous American study[1], although significant differences were not found, the incompatible matings were more fertile It is not clear why this apparent difference between Japanese and American populations should exist The facts that (*a*) ABO incompatibility is known to be a protection against *Rh* hæmolytic disease of the newborn[5] and (*b*) 15 per cent of the American couples of the present study were of the incompatible mating type ♂($Rh+$) × ♀($Rh-$), while almost all the Japanese couples were ♂($Rh+$) × ♀($Rh+$), do not explain this difference This is shown by the fertilities of the following two types of couples in the present study *Rh* compatible and ABO compatible, 1 711 ± 0 072, *Rh* compatible and ABO incompatible, 2 047 ± 0 109 These means differ significantly at the 0 01 level

These results will be presented in more detail elsewhere We wish to thank the authorities of the Michigan Civil Defense for permission to analyse these results This study was supported by grant *AT* (11-1)-405 from the United States Atomic Energy Commission

TABULAR COMPARATIVE DATA FOR THE LOW- AND HIGH-TEMPERATURE STRAINS OF *CHLORELLA*

By Dr CONSTANTINE SOROKIN

Department of Botany, University of Maryland, College Park, Maryland

THE isolation of unicellular high-temperature algae began in Texas in 1951[1]. Some characteristics of the high-temperature strains are scattered in several publications[1-5]. To give a unified picture they are presented in Table 1 together with the unpublished results. It cannot be too strongly emphasized that, for a particular strain, cell characteristics are strongly influenced by external conditions both prior to (preconditioning) and during actual measurements. With many factors affecting cellular characteristics, only an attempt can be made to present results obtained under specified conditions for two strains each representative of a distinct biological group of algae: Emerson strain, representing the group of low-temperature algae, and *Chlorella* 7-11-05, representing the group of high-temperature algae.

A detailed description of the technique of studying characteristics depicted in Table 1 has been given in previous publications[3,4,6]. Only a few remarks are in place. Results of respiration and photosynthesis were obtained in manometric experiments of short duration with cells from liquid stock cultures grown under constant apparently optimal growth conditions for each strain. After a 20-min temperature adjustment period, readings were taken for 30 min and calculated as the rates of the process per 1 hr. Growth results were obtained in experiments of long duration. Inocula from the same stock cultures as used for manometric experiments were transferred into test-tubes and subjected to conditions specified in Table 1. An extended time and several transfers were often required to allow cells to pass the adjustment period. The actual measurements in individual experiments continued for a time sufficient for optical density of the algal suspension to rise from about 0.07 to 0.7. Incandescent bulbs were used as a source of light in growth and photosynthesis measurements. For both strains the illuminance in growth studies, as measured at the level of growth vessels, was 1,600 ft.-candles and in photosynthesis studies was about 2,000 ft.-candles.

Temperature optima for growth, indicated in Table 1, were obtained for both strains at illuminance above the light-saturating point. It should be emphasized that at lower light intensities the optimum for growth moves to lower temperatures and the upper limit extends to higher temperatures. Temperature optima and upper temperature limits for respiration and photosynthesis are higher in short-time manometric experiments than those for growth. However, it could be demonstrated that the dependence of metabolic characteristics on temperature is a time phenomenon. With the progress in manometric experiments the optima and maxima usually move to lower temperatures.

For endogenous respiration the importance of the time factor is augmented by the dependence of the rate of the process on the amount of respirable material left in algal cells. Even under optimal conditions the time course of endogenous respiration, as observed in manometric experiments, is described by falling rates. Our attempt to obtain values for endogenous respiration of cells, as they intensively grow under optimal conditions, produced much higher values—close to those of glucose respiration.

Values for the rates of glucose respiration, photosynthesis and growth are much more stable if

measured under optimal conditions for growth. This is true also for the high-temperature strain at 25° C. It is noticed that at 25° C. the rates of growth, respiration and photosynthesis are close or slightly higher for *Chlorella* 7-11-05 than for the Emerson strain. However, if compared at a temperature optimal for their growth, the Emerson strain has about 3 doublings and *Chlorella* 7-11-05 more than 9 doublings of cell material per 24-hr. period. With further refining of the technique, 10 doublings per day are readily obtainable. This gives an 8-fold increase of cell material for a 24-hr. period for the Emerson strains and 1,000-fold increase for *Chlorella* 7-11-05. The rate of photosynthesis in the high-temperature algae is 4 times higher at light saturation than in low-temperature algae and 3.6 times higher at half-saturation. For growth the corresponding figures are 3 and 2.9.

The greater productivity of higher-temperature algae in comparison with low-temperature strains is due to the ability of the high-temperature algae to use higher temperature and illuminance levels. This is indicated by much higher positions of light-saturating points for growth and photosynthesis in the higher-temperature algae. The suggestion, that for the low-temperature strain the saturating light intensity for growth is slightly higher than that for photosynthesis and for the high-temperature strain the relationship is reverse, is probably of no significance since the determination of light-saturating intensity involves some degree of approximation.

A most general characteristic of the high-temperature algae is their higher responsiveness to the increase (within limits) in temperature and in incident light energy. In this respect they actually are higher-efficiency algae. The term 'efficiency' here is an expression of two processes—the absorption of the incident energy and conversion of the absorbed energy into the product which is used for measuring the rate of the process. Its pragmatic usefulness is based on the fact that it describes the performance of the organism at high levels of temperature and light energy. The highest levels of the incident energy are of utmost importance for the organism of high productivity capable of using temperatures and light intensities which are of no use if not harmful for the low-efficiency (low-temperature) strains.

PHOTOCHEMICAL AND STEREOCHEMICAL PROPERTIES OF CAROTENOIDS AT LOW TEMPERATURES

By STAFF OF THE BIOLOGICAL LABORATORIES OF
HARVARD UNIVERSITY, CAMBRIDGE, MASS.

IN this series of articles we report the results of measurements carried on in this laboratory over the past six years. They involve the absorption spectra of carotenoids and haplo-carotenoids (vitamin A, retinene) at temperatures between 25° and − 196° C. The most important single result of these measurements is to demonstrate that cooling such molecules relieves certain instances of steric hindrance ('intramolecular overcrowding')[1], with large effects upon the absorption spectrum and other properties.

The first communication records three observations which, though all made with retinene, have some general interest: (1) the abnormally large changes exhibited by the absorption spectrum of a sterically hindered *cis* carotenoid on cooling; (2) the capacity of a carotenoid to undergo *cis–trans* isomerization at low temperatures in a rigid solvent; and (3) a more specific observation, a new instance of reversible photobleaching.

In the second communication we examine further the first of these phenomena, and show that the absorption spectra of all-*trans* and unhindered-*cis* configurations of retinene, vitamin A, vitamin A_2, lycopene and β-carotene exhibit parallel changes on cooling; whereas those of sterically hindered configurations of these molecules display the abnormally large changes first observed with retinene alone. The third communication discusses the significance of these observations.

(1) Photochemical Behaviour of Retinene

By DR. LAWRENCE JURKOWITZ

IN these experiments retinene (vitamin A aldehyde, $C_{19}H_{27}CHO$; Fig. 1) was dissolved in the mixtures of ether, isopentane or isohexane (3-methyl pentane) and alcohol (5:5:2) called *EPA* and *EHA*[2]. Such solutions were brought to temperatures close to that of liquid nitrogen (− 196° C.), at which *EPA* and *EHA* become so highly viscous as to form what are essentially clear glasses.

The measurements were made in a Dewar flask designed by Dr. R. C. C. St. George, mounted in a special housing which could be substituted for the standard cell compartment of a Beckman *DU* spectrophotometer. The Dewar flask was silvered throughout except for a clear band at the level of the light path, serving as window. It was made of

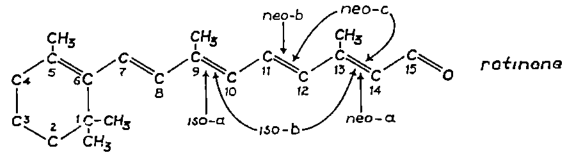

Fig 1 Structural formula of all-*trans* retinene Above and below the formula are indicated the positions of the *cis* linkages in known geometrical isomers Unhindered isomers below iso-a (9-*cis*), neo-a (13-*cis*), and iso-b (9,13-*dicis*) Sterically hindered isomers above neo-b (11-*cis*) and neo-c (11, 13-*dicis*)

'Pyrex' glass, and had a high transmission only for wave-lengths longer than about 320 mμ The Dewar was blown in the form of an H, with two vertical chambers connected by a horizontal section One of the chambers held the absorption cell Liquid nitrogen could be added from time to time through the other chamber without disturbing the absorption vessel, and this also provided an additional store of the coolant, which for this reason needed to be replenished less often The absorption cell could be lowered and raised, into and out of the light path of the spectrophotometer, and all measurements were made with the cell alternately in these positions That is, all absorptions were measured relative to the absorption of the Dewar flask without the absorption cell in position The level of liquid nitrogen was at all times below the absorption cell, and hence out of the path of light A 'blank' correction was obtained by measuring separately the absorption spectrum of the cell containing solvent alone under the same conditions A further correction involves the contraction of the solvent at low temperatures *EPA* and *EHA* were observed to contract fairly regularly on cooling Their volume at −190° is about 0 77 of that at room temperature The temperature of the solution in the absorption cell was followed continuously with an iron-constantan thermocouple immersed in it

All irradiations were performed with a high-pressure mercury arc lamp (General Electric *AH*5, 250 watts) mounted so that its radiation, having passed through a 'Lucite' cell containing a layer of water 2 5 in thick, could be focused with a glass lens directly upon the solution in the absorption cell The full radiation of the arc was employed, but enough glass lay between the lamp and the absorption cell to exclude wave-lengths shorter than about 320 mμ

(1) *Relief of steric hindrance at low temperatures* Retinene owes its absorption spectrum to the possession of five double bonds—four in the side-chain and one in the attached ring—all in some degree of conjugation with one another and with the terminal carbonyl group (Fig 1) The molecule exists in a variety of geometric configurations—*cis–trans* isomers —the most prevalent of which have been isolated, and their configurations established by synthesis[3] These include the all-*trans* isomer, the relatively unhindered 9- and 13-*monocis*, and 9, 13-*dicis* isomers, and the sterically hindered 11-*cis*, and 11, 13-*dicis* isomers (Fig 1)[4] The hindered 11-*cis* isomer (called also neo-b) has a special interest, since this configuration of retinene and retinene$_2$ serves as the chromophore of all the known visual pigments[5]

The absorption spectrum of all-*trans* retinene at room temperature consists of a single broad band, maximal in *EPA* at about 373 mμ (λ_{max}), and with a molar extinction coefficient, ε_{max}, of 47,600 (Fig 2) Brought to about − 185°, the absorption spectrum still displays no fine structure, but λ_{max} moves about 14 mμ toward longer wave-lengths, and ε_{max}, rises about 10 per cent Also the long wave-length toe or tail of the band is drawn in toward shorter wave-lengths Such changes are characteristic of polyenes brought to low temperatures (cf ref 6, also following communication)

The same experiment performed with the sterically hindered 11-*cis* isomer yields a very different result (Fig 2, right) A primary consideration that governs the behaviour of such molecules is the degree to which they achieve coplanarity, that is, to which they succeed in lying flat Only when coplanar can their systems of alternate single and double bonds come into full conjugation, the condition in which the absorption spectrum lies at longest wave-lengths, displays the most detailed fine structure, and has the largest maximal and integrated extinction Any loss of coplanarity—any twisting of the system—results in a loss of conjugation, with corresponding losses of extinction and fine structure, and usually also a shift of spectrum toward shorter wave-lengths

A *cis* linkage at position 11, since it brings into conflict the H atom on carbon 10 and the $-CH_3$ group on carbon 13, prevents coplanarity, causing a twist in the molecule at this level The result (Fig 2) is a considerable degradation of spectrum at room temperature, evident mainly in the depression of ε_{max} to 26,400—only 0 555 the ε_{max} of the all-*trans* isomer λ_{max} also lies at slightly shorter wave-lengths than in the all-*trans* isomer (at 369 mμ), a remarkably small change compared with other hindered *cis* polyenes[7]

On cooling to temperatures near that of liquid nitrogen, both λ_{max} and ε_{max} change so greatly as to approach the values observed in all-*trans* retinene at these temperatures λ_{max} shifts to about 385 mμ, and ε_{max} increases to about 43,000 (Fig 2, right) That is, whereas cooling to − 185° raises the ε_{max} of all-*trans* retinene about 10 per cent, it raises that of 11-*cis* retinene 62 per cent These changes are entirely reversed on warming It should be noted that the temperature to which we have brought these solutions is arbitrary, further cooling presumably would result in a further approximation of the 11-*cis* to the all-*trans* spectrum

It is as though cooling to about − 185° had largely relieved the steric hindrance associated with a *cis* linkage in position 11 This interpretation of

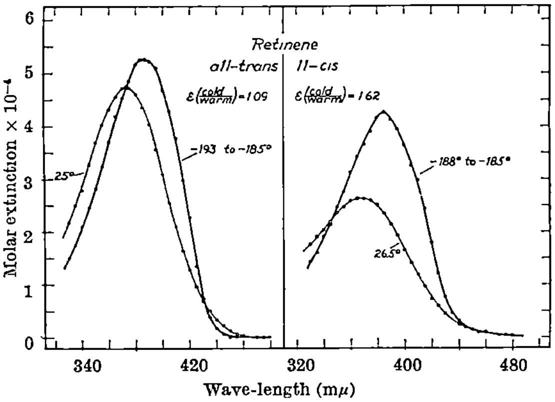

Fig 2 Absorption spectra of all-*trans* and 11-*cis* retinene, at room temperature and at that of liquid nitrogen Cooling raises the ε_{max} of the all-*trans* isomer 9 per cent, and that of the hindered 11-*cis* isomer 62 per cent

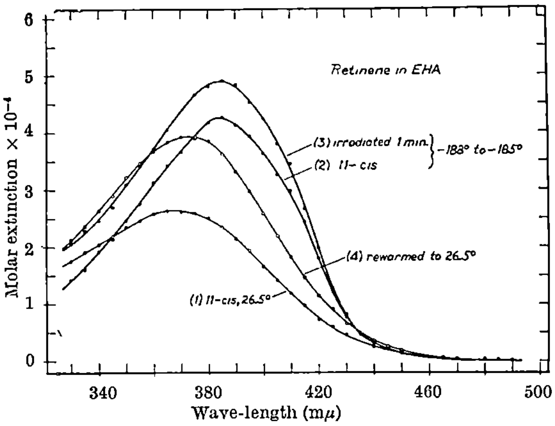

Fig 3 Geometrical isomerization of retinene by light at a low temperature in a rigid solvent (1) Absorption spectrum of 11-*cis* retinene in *EHA* at room temperature (2) Same at the temperature of liquid nitrogen, the solvent is vitrified (3) Irradiated 1 min in the cold (4) Returned to room temperature, in the dark The rise of ϵ_{max} in the cold, accentuated in the warm, is associated with the isomerization of the hindered 11-*cis* isomer to a steady state mixture of all possible isomers, primarily all-*trans*

the observations is pursued further in the communication which follows

(2) *Cis–trans isomerization* Retinene is isomerized by simple exposure to light Beginning with any single geometric isomer, this process ends with the production of a steady-state mixture of all possible isomers, the proportions of which vary with solvent and other conditions, but the major component of which is usually all-*trans*[8]

It occurred to us to ask whether this process would be inhibited by low temperatures, perhaps because it includes a thermal component[9], or by being carried out in a rigid solvent, which might restrict the necessary rotation about double bonds It should be noted that geometric isomers of retinene in the crystalline state are not isomerized, even by long exposure to bright sunlight (It must be conceded that our experiments to date leave it undecided whether this is owing to the crystalline state itself, or to failure of light to penetrate the crystal The specific extinction of retinene is so high that at λ_{max} the intensity of light is cut to 1 per cent after penetrating only about 0 12μ of the pure substance, so that the interior of even a small crystal might scarcely be affected by even a long and intense irradiation)

In the present experiment we used 11-*cis* retinene, which, being a hindered isomer and relatively unstable, isomerizes almost completely and with a particularly large change of extinction[8,10] A solution of 11-*cis* retinene in *EHA* was brought to about – 187°, and irradiated for 1 min (Fig 3) The extinction rose about 16 per cent, λ_{max} remaining almost unchanged On warming the product to room temperature, these changes were magnified compared with the spectrum before irradiation, the extinction had risen 1 5 times, and λ_{max} had shifted about 5 mμ toward longer wave-lengths, arriving close to the λ_{max} of all-*trans* retinene These are the changes that characteristically accompany the isomerization of neo-b retinene to the steady state mixture of isomers, primarily all-*trans*

All-*trans* retinene behaves very differently under these conditions On irradiation in *EHA* for 1 min at about – 185°, the extinction of this isomer falls about 2 per cent, and on re-warming to room temperature, the spectrum compared with that before irradiation had fallen 1 3 per cent in extinction, with no appreciable change in λ_{max} Once again, this behaviour is characteristic of the isomerization of the all-*trans* isomer to a mixture containing small amounts of *cis* isomers, all lower in extinction

It may be concluded that neither the low temperature nor a rigid solvent inhibits the geometric isomerization of this molecule The process appears to go about as well in these circumstances as at room temperature Apparently the rigid solvent leaves the molecule sufficient 'elbow room' to allow free play for the rotations involved in geometric isomerization

(3) *Reversible photo-bleaching* In this experiment, all-*trans* retinene in *EPA* was brought to the temperature of liquid nitrogen, and exposed to the full radiation of the mercury arc As stated earlier, however, only wave-lengths longer than 320 mμ penetrated to the sample It should be noted that no particular precautions were taken to exclude oxygen or water vapour

The effects of the irradiation are shown in Fig 4 In 30 min the maximum extinction, at 387 mμ, had fallen to about 60 per cent, and in another 30 min to about 20 per cent of its initial value Small new maxima had appeared at about 350 and 412 mμ

On re-warming this solution to room temperature, the absorption rose again, not indeed to its original height at room temperature, yet to 87 per cent of it, and λ_{max} returned approximately to its original position Some of the fall in final extinction is caused by isomerization, owing to the irradiation, from the all-*trans* configuration to the steady state mixture of isomers already described, the remainder probably involves some destruction of pigment

The major change in this experiment, however, was the photo-bleaching at low temperature, reversed (except for the concomitant isomerization) on re-warming to room temperature The same phenomenon has been observed also with all-*trans* retinene dissolved in *EH* amine (ether, isohexane, triethylamine, 5 5 2) On irradiation at about – 187°, the extinction falls, and a new maximum develops at about 350 mμ and a minimum at about 368 mμ Again, on warming, these changes are largely

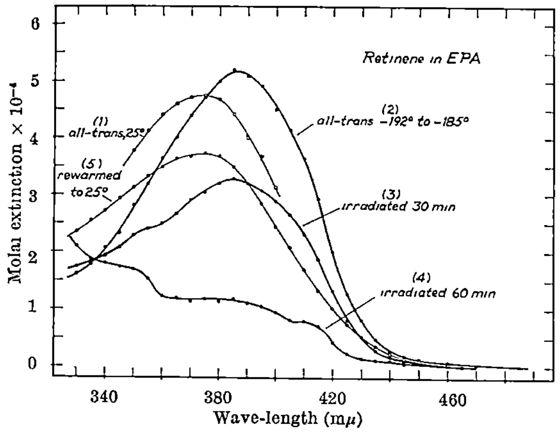

Fig 4 Reversible photobleaching of retinene at low temperature in a rigid solvent (1) All-*trans* retinene in *EPA* at room temperature (2) Same brought to liquid nitrogen temperature (3) Irradiated 30 min in the cold, ϵ_{max} falls 40 per cent (4) Irradiated 30 min longer, ϵ_{max} has fallen 80 per cent (5) Rewarmed to room temperature in the dark Most of the original extinction is regained, what has been lost is due mainly to the light having isomerized the all-*trans* retinene to a steady state mixture of *cis* and *trans* forms

reversed, the band at 350 mμ disappearing, and the retinene band rising to nearly its original height. On the other hand, similar experiments with retinene$_2$ dissolved in *EPA* and *EH* amine have not displayed photo-bleaching.

This photo-bleaching of retinene resembles somewhat, in the character of the spectral change, the production of a metastable (triplet ?) state in chlorophyll by exposure to a brief, very intense flash of light[11]. The present product, however, appears to be too long-lived to represent a triplet state. It may correspond rather to the formation of a pair of free radicals or ions, trapped in the rigid solvent, but able to recombine on warming to reconstitute normal retinene. In this regard the reversible photo-bleaching of retinene may resemble another mode of photo-bleaching of chlorophyll, discovered some years ago by Porret and Rabinowitch[12], yet which demanded a degree of exclusion of oxygen probably not achieved in the present experiments.

(2) *Cis-trans* Isomerism and Steric Hindrance

By JOHN N. LOEB, PAUL K. BROWN and PROF. GEORGE WALD

HAVING observed one instance in which cooling to the temperature of liquid nitrogen largely abolished the degradation of spectrum associated with a sterically hindered *cis* linkage, we wished to learn how general this phenomenon may be, and how related to other aspects of molecular geometry. With this object in view, we have examined the spectra of geometrical isomers of retinene, vitamin A and A$_2$, lycopene and β-carotene at room temperature and at that of liquid nitrogen. The procedures were as already described, except that for the measurement of vitamin A we used a quartz Dewar flask and quartz absorption cell in place of the 'Pyrex' vessels used otherwise.

(1) *Retinene*. The most extensive set of geometric isomers of known constitution now available is offered by the stereoisomeric retinenes. We have already described the changes of spectrum on cooling the all-*trans* and the hindered 11-*cis* isomer. In the present experiments these measurements were extended, and similar measurements performed with the relatively unhindered 9-*cis*, 13-*cis* and 9,13-*dicis* isomers (Fig. 1)[3b]. These measurements are summarized in Table 1, and the changes of extinction with temperature are shown in Fig. 5.

As already noted, the all-*trans* isomer on cooling to about – 185° C. exhibits a displacement of λ_{max} of about 14 mμ toward longer wave-lengths, and a rise of ε_{max} of about 10 per cent. Very nearly the same changes are displayed by all the unhindered *cis* isomers, so that they, together with the all-*trans* isomer, show on this degree of cooling an average displacement of λ_{max} of 13 mμ, and an average rise of ε_{max} of 11 per cent. This correspondence in behaviour is evident in Fig. 5 in the close parallelism of the lines describing the change of ε_{max} with temperature for these isomers.

The extraordinary behaviour of the 11-*cis* isomer is especially evident in this context. To examine this more closely we have measured the spectra of all-*trans* and 11-*cis* retinene at intermediate temperatures between 25° and – 185° C.; the variations of ε_{max} over this temperature range are included in Fig. 5.

On cooling all-*trans* retinene, ε_{max} rises linearly over the entire range of temperatures. The 11-*cis* isomer exhibits altogether different behaviour. Having begun at room temperature far below that of any of the other *cis* isomers, the ε_{max} of 11-*cis* retinene rises so rapidly on cooling that by the temperature of liquid nitrogen it has become higher than that of the unhindered 9,13-*dicis* isomer, and as high as those of the unhindered 9- and 13-*monocis* isomers. One would expect that having achieved this position, ε_{max} should continue to rise at still lower temperatures in parallel with the rise of the unhindered *cis* isomers; yet this would demand a considerable decrease in slope, of which there is no hint in the data of Fig. 5. Indeed, the rise of ε_{max} in the 11-*cis* isomer proceeds in two stages, each linear with temperature, a relatively slow change from room temperature to about – 100°, and a considerably more rapid further change to about – 185°. The significance of the break in the curve and change of slope is not yet clear; but it makes all the more problematical the course of this function at still colder temperatures.

Incidentally, these measurements show that the effects of cooling are regular and continuous. They go primarily, therefore, with the change of tem-

Table 1. EFFECTS OF COOLING UPON CAROTENOID SPECTRA

* Averages from three sets of measurements.
† Averages from four.
‡ Averages from two.
§ For carotene and lycopene, ε_{max} and λ_{max} are of the 'middle' maximum, that of next-to-longest wave-length.

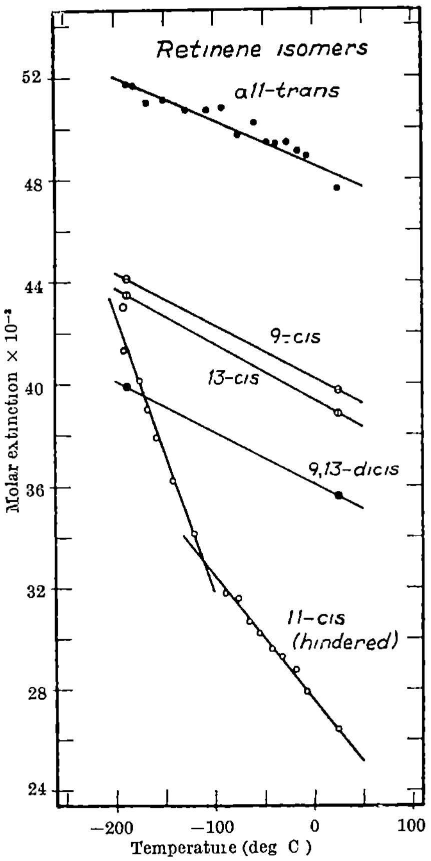

Fig 5 Rise of maximum extinction (ε_{max}) of geometric isomers of retinene on cooling to liquid nitrogen temperature The all-*trans* and unhindered *cis* isomers exhibit parallel changes, ε_{max} rising on the average 11 per cent In the hindered 11-*cis* isomer, ε_{max} rises in two linear stages, a total of 62 per cent The significance of the break in the latter function is not known

perature and not with vitrification of the solvent, which becomes apparent only at very low temperatures, below − 160°

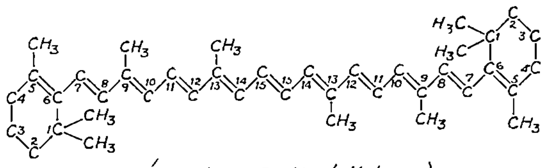
It is a striking characteristic of the 11-*cis* isomer that though its sterically hindered configuration greatly depresses ε_{max}, it has little effect on λ_{max}, which is displaced from the all-*trans* position no more than in other *monocis* configurations By the same token, cooling has no greater effect on the λ_{max} of the 11-*cis* isomer than on the others Furthermore, the change of λ_{max} with temperature for this as for the other isomers is simple and linear, with no evidence of such a break as appears in the function for ε_{max}

(2) β-*Carotene* The spectrum of all-*trans* β-carotene ($C_{40}H_{56}$, Fig 6) exhibits three absorption maxima in the visible region, the central one of which has the highest extinction (Fig 7) These maxima constitute vibrational fine structure superimposed upon a broad absorption band which represents a single electronic transition from the ground to the first electronically excited state On cooling to the temperature of liquid nitrogen, the spectrum as a whole is displaced toward longer wave-lengths, and the fine structure is greatly accentuated, five maxima now being distinguishable Now also the absorption maximum of longest wave-length has the highest extinction Ordinarily in carotenoid spectra the band of next-to-longest wave-length is highest, and this maximum also can most readily be compared with cases in which no vibrational fine structure appears, the entire absorption taking the form of a single, broad band For these reasons our measurements are summarized in Table 1 and Fig 8 in terms of the central maximum A more significant index is the area under the entire absorption band A comparison on this basis is shown in Table 2 (below).

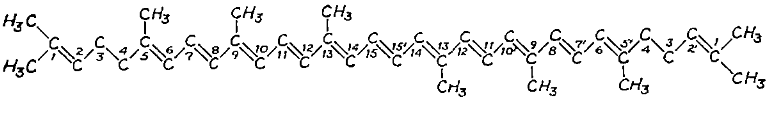
On cooling to about − 185°, the central maximum in all-*trans* β-carotene is displaced about 17 mμ toward longer wave-lengths, and rises 32 per cent in extinction Similar measurements were made upon all-*trans* lycopene, $C_{40}H_{56}$, the straight-chain isomer of β-carotene (Fig 6) with similar results (Table 1) On cooling, its central maximum was transposed about 12 mμ toward longer wave-lengths, and the extinction rose 46 per cent

As an example of an unhindered *monocis* β-carotene, we have examined the 15,15′-*monocis* isomer (hereafter called 15-*cis*), prepared synthetically[13] Such a centrally placed *cis*-linkage causes a maximum bending of the molecule, and is associated with a particularly tall '*cis*-peak'[14] in the near ultra-violet at about 340 mμ The ε_{max} of 15-*cis* β-carotene is only 71 per cent as high as that of the all-*trans* isomer, but on cooling to about − 185°, this spectrum undergoes parallel changes (Fig 8) Once again λ_{max} is displaced 16 mμ toward longer wave-lengths, and ε_{max} rises 42 per cent. As in the retinenes, cooling has about the same effect on the unhindered *cis* isomer as on the all-*trans* configuration

15-*monocis* β-carotene offers a particularly good opportunity to examine the effects of cooling upon a *cis*-peak At room temperature the *cis*-peak of this molecule consists of a single band, maximal at about 335 mμ in *EPA*, and with ε_{max} 58,500, almost 60 per cent as high as the main absorption band On cooling to about − 185°, the maximum moves to about 349 mμ—a shift of about 14 mμ, slightly less than in the main band—and ε_{max} rises about 9 per cent—very much less than in the main band This difference in the effect of cooling on ε_{max} is probably



β-carotene, $C_{40}H_{56}$ (all-trans)



lycopene, $C_{40}H_{56}$ (all-trans)

Fig 6 Structures of all-*trans* β-carotene and lycopene These isomeric carotenoid hydrocarbons differ mainly in that lycopene is straight-chain, whereas β-carotene possesses terminal β-ionone rings The latter are twisted out of coplanarity with the side-chain, owing to steric hindrance between the methyl groups at 1, 1′ and the H atoms at 8, 8′, so causing a large loss of conjugation of the ring double bonds with the straight-chain portion of the molecule

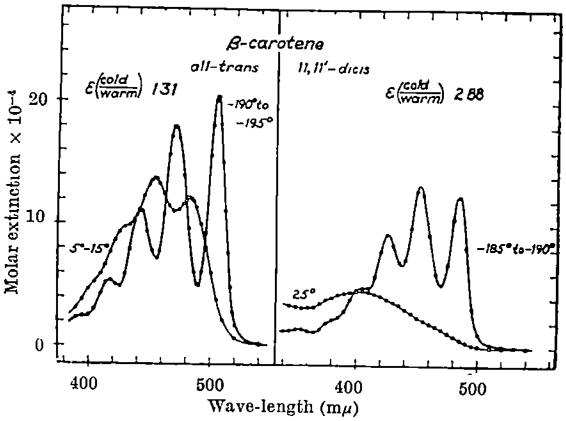


Fig. 7. Absorption spectra of all-*trans* and 11,11'-*dicis* β-carotene in *EPA* at room temperature and at that of liquid nitrogen. On cooling, the maximal extinction of the 'middle' band (that of next-to-longest wave-length) rises 31 per cent in the all-*trans* isomer, and 188 per cent in the hindered *cis* isomer. The spectra measured in the cold display five distinct maxima, representing transitions from the 0 vibrational level of the ground electronic state to five vibrational levels of the first electronically excited state

not very significant; in both cases the area of the band remains practically unchanged (cf. Table 2). On the whole, it may be concluded that the effect of cooling is much the same on the *cis*-peak as on the long-wave-length absorption.

As in the retinenes, however, a hindered *cis* isomer behaves very differently. As example of such a form we have examined 11,11'-*dicis* β-carotene, prepared synthetically[15]. This molecule contains, symmetrically placed, two hindered *cis* linkages like that of 11-*cis* retinene. The absorption spectrum in the visible region is greatly degraded at room temperature, consisting of a single broad band displaying no fine structure, with ε_{max} only 33.6 per cent as high as that of all-*trans* β-carotene, and λ_{max} displaced about 50 mμ toward shorter wave-lengths (Fig. 7). On cooling to about − 185°, this spectrum changes out of all proportion with the all-*trans* and 15-*cis* isomers: ε_{max} rises 2.90 times, approaching close to the ε_{max} of 15-*monocis* carotene (Table 1, Fig. 8), and λ_{max} is displaced 49.5 mμ towards longer wave-lengths. In addition, the spectrum in the cold exhibits all the fine structure characteristic of unhindered isomers of β-carotene. As with 11-*cis* retinene, there is every appearance that cooling to this degree has almost wholly relieved the steric hindrance.

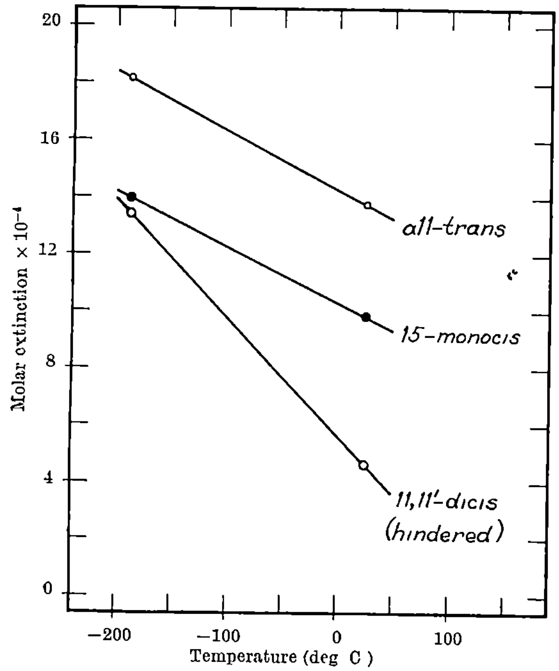

Fig. 8. Effect of cooling on the maximal extinction of geometric isomers of β-carotene. The ε_{max} recorded is that of the 'middle' (next-to-longest wave-length) band. The changes in the all-*trans* and unhindered 15-*cis* isomers are nearly parallel. The hindered *cis* isomer exhibits a much larger change

(3) *Vitamin A*. The attempt to perform similar measurements with vitamin A ($C_{19}H_{27}CH_2OH$) encounters special difficulties. These measurements must extend further into the ultra-violet than with the other polyenes; hence we transferred to a quartz Dewar flask and quartz absorption cell. Unfortunately also, a large solvent 'blank', and consequent impairment of the accuracy of measurement, develop below 330 mμ.

What is more troublesome is that vitamin A fluoresces strongly at room temperature, and brilliantly at the temperature of liquid nitrogen. In the Beckman spectrophotometer as ordinarily employed, much of the fluoresced light is picked up by the photocell, and recorded as if it were a decrease of extinction. The error so introduced is negligible at room temperature, but considerable in the cold, both because of the increased fluorescence, and because the need to open the slit of the spectrophotometer widely at short wave-lengths greatly increases the radiation incident on the solution. In our first measurements, having done nothing to temper this effect, we were surprised to find that, unlike all the other polyenes measured, vitamin A appeared not to rise in extinction on cooling. In the later measurements to be described, we inserted a Jena *UG*-1 filter, which transmits light only between about 320 and 400 mμ, between the Dewar flask containing the absorption cell and the photocell, so removing at least the visible fluorescence. This helped somewhat to bring the measurements on vitamin A into line with those on other polyenes, but was not wholly adequate, since fluorescence in the near ultra-violet still reached the photocell.

The absorption spectra of all-*trans* and 11-*cis* vitamin A, measured in *EPA* at room temperature and in the cold, are shown in Fig. 9. The changes in λ_{max} and extinction which occur on cooling are summarized in Table 1 and Fig. 10.

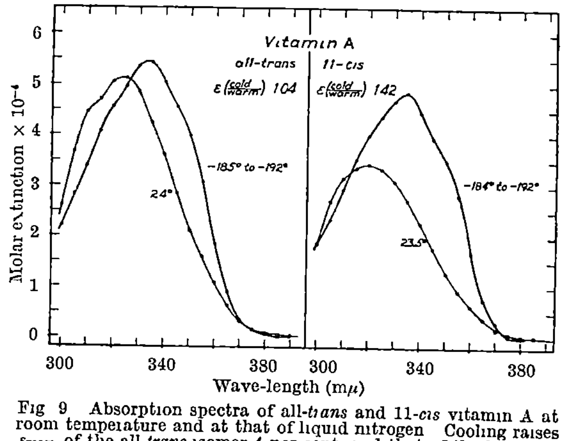

Fig. 9. Absorption spectra of all-*trans* and 11-*cis* vitamin A at room temperature and at that of liquid nitrogen. Cooling raises ε_{max} of the all-*trans* isomer 4 per cent, and that of the hindered *cis* isomer 42 per cent

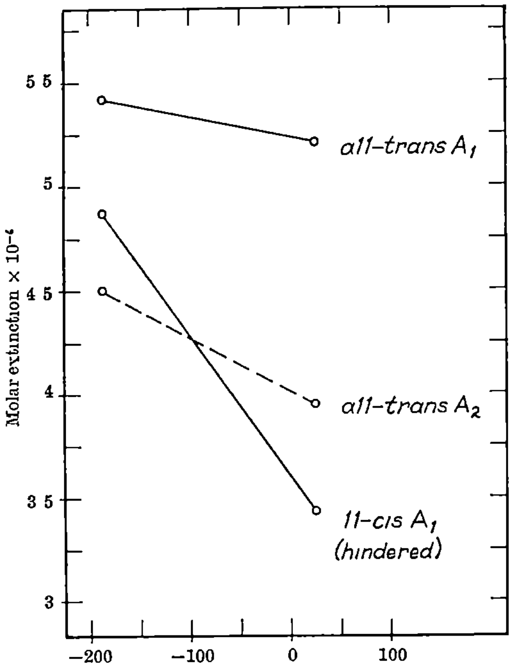

Fig. 10. Effects of cooling on ε_{max} of all-*trans* and 11-*cis* vitamin A and all-*trans* vitamin A_2. Vitamin A_1 fluoresces so intensely in the cold that it appears to absorb less than is actually the case. The change in ε_{max} exhibited by vitamin A_2 is probably more nearly correct for both all-*trans* molecules. The hindered *cis* vitamin A_1 exhibits a much larger change, though here again the change is under-estimated because of strong fluorescence in the cold.

When the all-*trans* isomer is cooled, λ_{max} is displaced about 9.5 mμ toward longer wave-lengths. The absorption band acquires also a degree of symmetry that is lacking at room temperature, shoulders appearing on each side of the maximum, reminiscent of the three-banded structure of the polyene hydrocarbons. The extinction meanwhile rises only about 4 per cent, perhaps owing to the under-correction for fluoresced light already noted. From this point of view some special interest is attached to the behaviour of all-*trans* vitamin A_2, which does not fluoresce strongly; on cooling, its extinction rises 14 per cent (Table 1, Fig. 10).

As with the other polyenes examined, the hindered 11-*cis* isomer of vitamin A exhibits special behaviour. Cooling this isomer shifts λ_{max} only slightly more than in all-*trans* vitamin A_1 or A_2, as was the case with the retinene isomers; but ε_{max} rises 42 per cent, and would probably have risen more if the fluorescence had been adequately controlled. Whereas the extinction of 11-*cis* vitamin A is only 66 per cent of that of the all-*trans* isomer at room temperature, in the cold its extinction rises to 90 per cent of that of the all-*trans* isomer, with simultaneous development of comparable evidences of fine structure, in the form of inflexions lying at both sides of the maximum.

Conclusion. This examination of the absorption spectra of all-*trans* and *cis* isomers of retinene, β-carotene, lycopene and vitamins A and A_2 shows that whereas all-*trans* and unhindered *cis* isomers exhibit parallel behaviour on cooling, sterically hindered *cis* isomers exhibit abnormally large changes of spectrum, including very large increases of extinction, as though cooling had largely or completely relieved the hindrance.

(3) Discussion

By Prof. GEORGE WALD

The unique feature of the carotenoids is that they possess conjugated systems of alternate single and double bonds in linear array. This arrangement not only lends them colour—a property of all extensive conjugated systems—but also the capacity to undergo large changes in shape through *cis–trans* isomerization[14]. In other types of pigment, natural and synthetic, the conjugated systems are mainly bound in rings, and hence held rigidly in position. Exposure to light is one of the most general means for causing *cis–trans* isomerization; and the relatively unrestricted capacity of carotenoids to change their shape in the light is probably the main reason for their special position in animal and plant photoreception[16].

The absorption of light goes with the possession of particularly mobile electrons, associated not with single atoms or bonds, but with the conjugated system as a whole[17]. In valence bond theory this special electronic mobility is embodied in the concept of resonance or mesomerism: the molecule is regarded as a hybrid of all the possible electronic configurations that can be associated with a given constellation of atoms. In molecular orbital theory, the same effect is achieved with the concept of overlapping π-orbitals, occupied by π-electrons which move more or less freely through the entire conjugated system.

Resonance, or the presence of π-electrons (whichever semantic one prefers), lowers the energy required to raise an electron from the ground state to the first excited state, hence poising the absorption at relatively long wave-lengths; and also greatly increases the probability of such transitions, with a consequent intensification of absorption. These are the properties that characterize a pigment.

The spectra considered in the present experiments, except for a passing reference to the *cis*-peak of β-carotene, represent such transitions from the ground to the first electronically excited state. Fine structure, when evident, is caused by superimposed changes of vibrational state (Fig. 12).

The most significant aspects of these spectra are: (1) Their wave-length range, a measure of the energies involved in the electronic transition (Fig. 12), through the relation $\Delta E = Nh\nu = Nhc/\lambda = 2.854 \times 10^7/\lambda$, in which ΔE, the energy of the transition, is expressed in gram calories per mole of quanta, and λ in mμ. (2) The width of spectrum and detail of fine structure. In general, a narrow spectrum and sharp fine structure are signs of the simplification of vibrational changes. Any increase in the variety of such changes, through the overlapping of bands, tends to broaden the spectrum and to wash out detail. (3) The area under the absorption band, when it is plotted on a frequency scale ($\int \varepsilon_\nu d\nu$). This is a measure of the probability of the electronic transition[18]. If the absorption band is reasonably symmetrical and lacks fine structure, the product of ε_{max} and the half-width of the band ($\varepsilon_{max}\ \Delta\nu_{1/2}$) does nearly as well; but these conditions are not usually fulfilled by carotenoid spectra. ε_{max} itself, though frequently involved in theoretical discussions, has little physical meaning, and offers only a rough hint of whether the band area has changed.

For conjugation to be strong, the atoms which compose the conjugated system must lie approximately in a plane It is only then that π-orbitals can overlap or resonance occur[19] Any departure from coplanarity—any twisting of the system—interferes with conjugation to a degree depending upon the angle of twist[20] The result is to depress the probability and usually to increase the energy of the lowest order of electronic transitions, so decreasing the area of the longest wave-length band, and usually shifting it toward shorter wave-lengths

Simple bending of the conjugated chain, even though in a plane, also affects the absorption spectrum Polyenes absorb most strongly when the electric vector of the light is parallel with the long axis of the conjugated chain A polyene in the all-*trans* configuration is linear (except for the regular zigzagging between carbon atoms) and is at its longest extension (Fig 11*a*) In this state its absorption is concentrated in a single electronic transition, and lies at relatively long wave-lengths Any bending of this structure, such as is caused by a *cis* linkage, shortens it, and at the same time opens a new axis of absorption at right angles to the main axis (Fig 11*b*) The result is a decrease in the area, and usually the height, of the main absorption band, and the appearance of a new absorption band (the *cis*-peak), associated with the new absorption vector, lying at shorter wave-lengths than the main band and polarized at right angles to the main band[21]

Mulliken[17a,d] has derived the approximate expression, $\epsilon_{\max} \propto l^2$, in which l is the length from tip to tip of the conjugated system The greatest shortening is caused by a central *cis* linkage, which bends the whole system at an angle of about 120°, shortening it to about 87 per cent (that is, cos 30°) of its all-*trans* length (Fig 11*b*) By Mulliken's formula this should diminish $\epsilon_{\max}$ to 75 per cent of the all-*trans* value The available measurements tend to show somewhat larger decreases of $\epsilon_{\max}$ (compare all-*trans* and 15-*cis* β-carotene in Table 1) Furthermore, a *cis* linkage anywhere in the chain shifts $\lambda_{\max}$ 4–6 mμ toward shorter wave-lengths[14], an effect that is not a necessary consequence of simple bending in a plane Perhaps both departures from expectation are caused by the small twisting that may also be associated with 'unhindered' *cis* linkages (see below) On the other hand, as already noted, such theoretical arguments are properly pursued on the basis, not of $\epsilon_{\max}$, but of the area of the absorption band

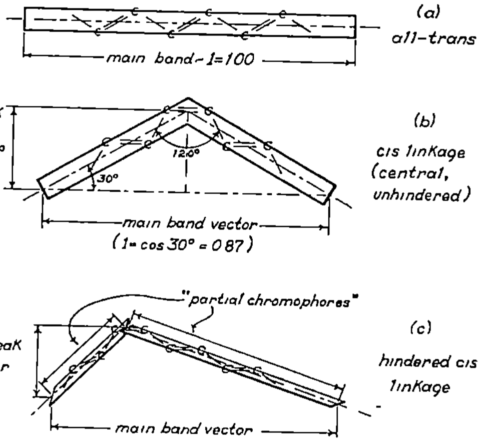

Fig 11 Diagram to show the absorption vectors of such conjugated systems as are present in the carotenoids The conjugated system of an all-*trans* carotenoid is coplanar throughout and at its longest extension An unhindered *cis* linkage bends the molecule, shortening the fundamental vector, and opening a new absorption vector polarized at right angles to this, responsible for the *cis*-peak A hindered *cis* linkage both bends and twists the molecule, resulting in absorptions corresponding not only to the main and *cis*-peak vectors, but to the 'partial chromophores' into which the conjugated system is divided by the break in coplanarity

Fig 12 Energy diagram of all-*trans* β-carotene, constructed from the data of Fig 7 (left) These results are re-plotted on a frequency scale at the top of the present figure The five maxima that appear in the cold represent transitions from the 0 vibrational level of the ground electronic state to five equally spaced vibrational levels (about 4 k cal apart) of the first electronically excited state The energy of the 0–0 transition is 59 1 k cal per mole in the warm, and 56 5 k cal in the cold In the warm a few transitions go from higher vibrational levels of the ground state, particularly short transitions of this type, shown here with broken lines, are responsible for a long-wave-length tail on the absorption band, which is lost in the cold (This difference does not emerge in the present spectra, though apparent in general) The areas under the successive maxima are an index of the transition probabilities In both warm and cold, the 0–1 transition is most probable Similar energy diagrams, differing only in numerical detail, can be drawn for 15-*cis* and (cold) 11,11′-*dicis* β-carotene, and for lycopene

In a sterically hindered *cis* linkage, the overlap of projecting groups causes a large departure from coplanarity At such a point, as already said, the conjugated system is both bent and twisted (Fig 11*c*) The bend, as always, is associated with a decrease in the fundamental absorption, and the appearance of a *cis*-peak In addition, the twist causes a partial break in conjugation, which to some degree divides the whole system into two shorter segments—'partial chromophores' Associated with the latter are subsidiary bands, lying at shorter wave-lengths than the fundamental band, and overlapping with the *cis*-peak, the main band, or both, depending on the lengths of the segments

It can be concluded that the absorption spectrum offers a variety of indices of molecular structure the linear co-ordinates of the conjugated system, its complexity of vibrational states, whether it lies bent or straight, whether twisted or in a plane With these notes as background, we may discuss the effects of cooling on the absorption spectra

General effects of cooling Cooling resulted in the same general pattern of changes in all our all-*trans* and unhindered *cis* carotenoids Many of these

Table 2. Effects of Cooling on the Areas of Absorption Bands

Carotenoid	Relative area		Ratio of areas (cold/warm)
	Room temperature	– 185° to – 195°	
Unhindered species			
Retinene, all-*trans*	320	317	0.99
9-*cis*	306	313	1.02

Relative areas, in arbitrary units, of the fundamental absorption bands, plotted on a scale of molar extinction versus frequency; that is, $\int \varepsilon \, d\nu$.

changes had been noted earlier in studies of diphenylpolyenes[6]. They include: (1) displacement of the spectrum toward longer wave-lengths; (2) ε_{max} rises, and the absorption band narrows; its area does not change (Table 2); (3) fine structure may appear, or be accentuated; (4) the long-wave length tail of the absorption band is abbreviated, so that usually it cuts off at shorter wave-lengths than in the warm.

These changes have a common basis, which can most readily be understood with reference to such a typical example as all-*trans* β-carotene, the energy diagram of which is shown in Fig. 12. Above the energy diagram are the absorption spectra from which it was derived, the curves of Fig. 7 (left) redrawn on a frequency scale.

The fundamental absorption band of β-carotene, as is apparent in the spectrum measured in the cold, possesses five maxima, representing transitions from the zero vibrational level of the ground electronic state to five vibrational levels of the first electronically excited state. The five absorption maxima are equally spaced, 1,430 cm.$^{-1}$ apart, corresponding to differences in the vibrational energy levels averaging 4.08 k.cal. per mole. The three peaks that appear in the warm clearly correspond to the first three peaks in the cold spectrum, and have almost the same spacing. That is, in both cold and warm, the first five vibrational levels of the first excited state are equally spaced about 4 k.cal. apart.

The absorption peak of lowest frequency measures the energy change corresponding to the 0–0 transition. At room temperature this peak occurs at 20,700 cm.$^{-1}$ ($\Delta E = 59.1$ k.cal.); in the cold it has shifted to 19,780 cm.$^{-1}$ ($\Delta E = 56.5$ k.cal.). That is, cooling the molecule has lowered the energy of the first electronic excitation by 2.6 k.cal., accounting for the displacement of the spectrum towards the red.

Though in the cold the highest extinction appears in the first band (0–0 transition), if the *areas* under the vibration bands are measured, these are seen to be largest in both the cold and warm in the second ('middle') band (0–1 transition). Such areas are an index of the relative probabilities of the various transitions, indicated in Fig. 12 below the energy diagram. The 0–1 transition is most probable at all temperatures.

All these features of the energy diagram, except for small numerical differences, are shared by 15-*cis* and 11,11′-*dicis* β-carotene (cold) and by lycopene.

At room temperature a small fraction of molecules is at higher vibrational levels of the ground state, from which transitions to the upper state involve smaller increments of energy, and hence longer wave-lengths of absorption. A few such transitions are shown in Fig. 12 with broken lines. A scattering of particularly short transitions of this kind accounts for the long wave-length tail on the absorption band in the warm. In the cold, virtually all transitions go from the zero vibrational level of the ground state, and this tail is lost. (Our measurements on β-carotene do not show this difference, though I think that more detailed measurements would have revealed it. It is apparent in many of our other spectra.)

Why do all polyene spectra that have been examined rise in extinction, that is, sharpen in structure, and shift toward the red on cooling? The shift towards the red, as just said, is an expression of the lowering of the transition energy between the ground and first excited state. It may be supposed that in the warm, molecular motions, in part the result of collisions, bend and twist the conjugated system from moment to moment so as to produce effects that resemble statistically those of *cis* linkages, hindered and unhindered. In the cold and in a rigid solvent, the molecule is subjected to less deformation, and can maintain relatively undisturbed its most extended and planar conformation. Such a view raises no serious energetic difficulties, for the mean thermal kinetic energy at room temperature is about 0.9 k.cal. per mole (3/2 RT), which is of about the right magnitude to produce the minor bendings and interruptions of conjugation that would account for the displacement of spectrum toward shorter wave-lengths and the fall of extinction and broadening that we observe in the warm. The effects of warming can mimic those of a *cis* linkage only qualitatively; for an actual *cis* linkage is fixed in position in all molecules of one species, whereas warming causes transient and fluctuating effects, different in all members of the molecular population.

It seems to me that this hypothesis involves several theoretical consequences that should be mentioned, though they do not emerge in the present measurements. If it is true that the molecule achieves more perfect conjugation in the cold than in the warm, this should result in an increased resonance energy, and a consequent lowering of the ground state as well as the first excited state. Furthermore, one should expect the area of the absorption band to be larger in the cold than in the warm, just as it is larger in the all-*trans* than in *cis* configurations; as Table 2 shows, within the accuracy of the present measurements, the areas are the same at room temperature and in the cold. Finally, I think one should expect to find higher absorption in the warm in the ultra-violet, owing to contributions from new absorption vectors and partial chromophores. Perhaps more detailed investigation will uncover all these effects.

Cooling and steric hindrance. It was shown above that sterically hindered *cis* carotenoids exhibit abnormally large changes of spectrum on cooling, as though lowering the temperature had relieved the hindrance. ε_{max} rises, and λ_{max} shifts toward the red, so as to approach the properties of an unhindered *cis* molecule.

More significant than either of these effects is the behaviour of the *area* of the absorption band. As shown in Table 2, though the areas of the main absorption bands of all-*trans* and unhindered *cis* carotenoids are approximately the same in the warm and cold, those of 11-*cis* retinene and vitamin A

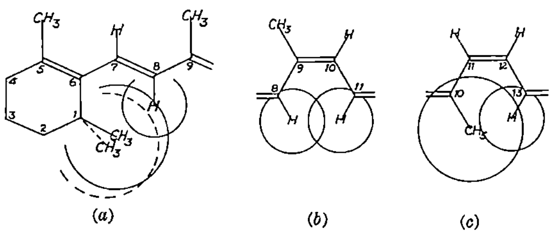

Fig. 13. Three sources of intramolecular steric hindrance encountered in carotenoids. (a) Hindrance between methyl groups on a β-ionone ring and a hydrogen atom on the side-chain. What is believed to be the prevalent s-*trans* orientation is shown here. (b) Hindrance between H atoms at an 'unhindered' *cis* linkage. It is only when H is given a van der Waals radius of 1.2 A. that the overlap shown here occurs. At a radius of 0.85 A. or less there would be no hindrance. (c) Hindrance between a methyl group and H at a hindered *cis* linkage. Only this last type of hindrance appears to be appreciably relieved by cooling

increase about 40 per cent, and that of 11,11′-*dicis* β-carotene increases just twice as much, about 80 per cent, on cooling to liquid-nitrogen temperature.

Such molecules present three sources of steric hindrance (Fig. 13): (*a*) overlap between the methyl groups on C_1 of the ring and the H atom on C_8, causing a twist between the ring and side-chain[22]; (*b*) overlap between H atoms at an 'unhindered' *cis* linkage. This is small, if it exists at all, yet is sometimes held responsible for the small shifts of spectrum toward shorter wave-lengths and some of the decrease of extinction that characterize such linkages[14]; (*c*) overlap of an H atom with a methyl group at such linkages as 11-*cis*.

Of these three types of hindrance, only one appears to be relieved by cooling. (*a*) Cooling does not change appreciably the hindrance between ring and side chain, as shown by the fact that it has parallel effects on β-carotene, which possesses two ionone rings, and lycopene, which has none (Tables 1 and 2). (*b*) Cooling does not relieve whatever overlap of H atoms may exist at 'unhindered' *cis* linkages, as shown by the fact that it has parallel effects on unhindered *cis* and all-*trans* carotenoids. (*c*) It can be concluded that cooling relieves specifically the steric hindrance at such linkages as 11-*cis*.

What is the mechanism of this effect? The geometry of molecules involves two kinds of dimension: the distances between bonded atoms, expressed in the bond radii, and the distances at which non-bonded atoms and groups begin to repel one another, expressed in the van der Waals radii. Instances of intramolecular steric hindrance seem as though they should involve van der Waals radii. These are generally estimated to be about 0.8 A. larger than the bond radii[23]. Yet estimates of intramolecular over-crowding made on this basis tend to predict larger effects than are observed; and values smaller than the van der Waals radii, perhaps at times approaching the bond radii, may be more applicable (cf. ref. 24).

I would suppose that the repulsion radius is made up not only of the space occupied by atomic structures, but includes also to a degree the space swept out by atoms and groups in their thermal stretching, bending and twisting motions. In this sense the close approach of such groups must give rise to a soft rather than a hard hindrance. It is equivalent, not to the contact between rigid surfaces, but rather to a fluctuating interpenetration of 'Lebensraume', that involves considerable 'give'.

I would suppose that lowering the temperature, by quieting down the thermal stretching, bending and twisting motions of attached groups, effectively contracts their van der Waals radii. This is the same type of effect that we have already invoked with regard to the conjugated chain. It is this effect that I think is primarily responsible for the relief of steric hindrance on cooling.

Why are hindrances of types (*a*) and (*b*) in Fig. 13 not relieved by cooling?

The hindrance between the ring and side-chain is probably considerably 'harder' than at an 11-*cis* linkage, because, in the s-*trans* configuration shown in Fig. 13, *two* methyl groups are in conflict with an H atom; and the ring holds these methyl groups more rigidly than would a straight chain[25].

The assumed hindrance between H atoms at an 'unhindered' *cis* linkage requires further consideration. Such hindrance exists if hydrogen is assigned the full van der Waals radius of 1.2 A.; but this value is probably too large to be applicable in the present instance. Braude has suggested that the onset of spectrally detectable effects owing to steric hindrance coincides better with a van der Waals radius of about 0.6 A. for hydrogen[24]; even if one expanded this to 0.8–0.9 A., no conflict would exist at an unhindered *cis* linkage, and the problem of relieving it by cold or otherwise would not arise. On the other hand, if this is a source of hindrance, one would not expect it to be relieved appreciably by cooling; for the stretching and bending energies of bonded hydrogen atoms are so large as scarcely to be activated even at room temperature[26].

For this reason also the relief of hindrance on cooling at such a linkage as 11-*cis* cannot appreciably involve the H atom, and must be ascribed almost entirely to the contraction of the effective van der Waals radius of the methyl group.

Implications and consequences. The assumption that the effective van der Waals radii contract considerably at low temperatures can be tested further, and made quantitative with the help of these and other kinds of measurement. In particular, X-ray crystallography at low temperatures should yield valuable information concerning the variation of van der Waals radii with temperature, and whatever molecular distortions accompany such changes. (I understand that such measurements have been made by W. N. Lipscomb at Minnesota and by Fankuchen at Brooklyn Polytechnic Institute, both of whom inform me in personal communications that cooling seems to have only very small effects on bond radii, and should have its principal effects on the distances of intermolecular and intramolecular contact.)

One interesting result of our observations is that, in the two instances in which measurements were made at intermediate temperatures (Fig. 5), ε_{max} rose linearly as the temperature was lowered, though in the case of 11-*cis* retinene an abrupt change in slope occurred at about – 100°, the reason for which is not known. The solvent is still highly fluid at this temperature, and continues so until below – 150°.

The temperature at which our measurements stopped was arbitrarily that of liquid nitrogen. At this temperature, as already noted, 11-*cis* retinene has achieved as high an ε_{max} as an unhindered *mono-cis* isomer. That is, it behaves as though its steric hindrance were entirely relieved; and judging from Figs. 8 and 10, this must be nearly the case also with 11,11′-*dicis* β-carotene and 11-*cis* vitamin A. Once the hindrance is gone, one should expect any further rise of ε_{max} with lowering of the temperature to have the same slope in all these molecules

The only data adequate to bear upon this point are those involving 11-*cis* retinene in Fig 5, and here there is no indication that this expectation will be realized The slope of the function would have to break very sharply to a lower value at temperatures just below that of liquid nitrogen, for $\varepsilon_{max.}$ of the hindered *cis* molecule not to rise rapidly *above* that of unhindered *cis* forms, a phenomenon we would be hard put to explain

From this point of view the band areas shown in Table 2 are more reassuring At − 190°, 11-*cis* retinene has a band area still only 0 77 as great as that of 9-*cis* retinene 11,11′-*dicis* β-carotene has a band area higher than that of 15-*monocis* carotene, as it should, since two *cis* linkages tend to compensate each other, bending the molecule less, and usually for this reason depressing the extinction less than one central *cis* linkage[14] Perhaps, therefore, as in other aspects of this problem, the argument encounters difficulties in terms of ε_{max} that are avoided when one considers instead the band area

The observation that steric hindrance is partly or wholly relieved at low temperatures has a curious consequence The twisting of the molecule occasioned by steric hindrance may, if sufficiently large, cause observable optical activity, depending upon whether the twist is to the right or the left In all but highly hindered molecules, since, as noted, such hindrances are 'soft', racemization occurs rapidly at room temperature, and ordinarily the single optical isomers cannot be isolated In several instances of large hindrance, however, racemates have been resolved, and the enantiomorphs are relatively stable[25,27] Our observations suggest that cooling such a single optical isomer, by decreasing the hindrance, might remove the barrier to racemization We should then observe the strange phenomenon of a chemical reaction, a racemization, activated by lowering the temperature This possibility should certainly be examined

Changes of absorption spectrum similar to those we have observed on cooling carotenoids in solution are observed in the warm when these and other pigments are embedded in solid or quasicrystalline structures So, for example, spectra of the visual pigments—all of which are retinene-proteins—exhibit a displacement of λ_{max} several mμ toward the red, and rise of extinction, when measured in the retina or in suspensions of whole or fragmented outer segments of rods[28] The latter are quasi-crystalline structures, in the sense that many of their molecules, including the visual pigments themselves, are oriented relative to one another[29] The same relations involve the spectra of the chlorophylls measured in cells or chloroplast suspensions, compared with their spectra in solution[30] In all these cases the spectrum in cell particles appears to differ from that measured in solution in much the same way that spectra at low temperatures in rigid solvents differ from those at room temperature Perhaps in solid structures, as in the cold, the quieting of thermal motions and relief from collision permit these pigments to maintain a less disturbed condition of linearity and coplanarity, with the consequent increase of target length and improvement of conjugation that yield the observed spectral changes

These investigations were supported in part by grants from the Rockefeller Foundation and the U S. Office of Naval Research We are indebted to Dr. H H Inhoffen for a gift of 15,15′-*cis* β-carotene, to Dr O. Isler for gifts of 11,11′-*dicis* β-carotene and vitamin A_2 acetate; to Prof L Zechmeister for lycopene; to Dr. W. Oroshnik for 11-*cis* vitamin A and retinene, and to the Organic Research Laboratory of Distillation Products Industries, Rochester, New York, for supplies of 9-*cis*, 13-*cis* and 9,13-*dicis* retinene

(Dr Jurkowitz—now at the University of Chicago Clinics—performed these experiments in the summer of 1955, following his first year at medical school Mr Loeb, now a third-year student at Harvard Medical School, was an undergraduate at the time of these experiments (1956–57))

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, October 19

Illuminating Engineering Society (at Caxton Hall, Caxton Street, London, S W 1), at 6 p m —Mr L J Davies "The Generation of Light" (Golden Jubilee Lecture)

University of London (at Birkbeck College, Malet Street, London, W C 1), at 6 p m —Prof E G Boring (Harvard University) "The Psychology of the History of Science" (First of three lectures on "The Pattern of Modern Psychology")*

British Association for the Advancement of Science in association with Granada TV Network (at the Guildhall, London, E C 2), at 8 30 p m —Dr Edward R Murrow Second of the Inaugural Series of the Granada Lectures on the theme of "Communication in the Modern World"

Royal Geographical Society (at 1 Kensington Gore, London, S W 7), at 8 30 p m —Sir Charles Darwin, F R S "Darwin the Traveller"

Tuesday, October 20

University College (in the Anatomy Theatre, Gower Street, London, W C 1), at 1 15 p m —Dr A W Stonier "The Differences between English and American Universities" *

Royal Institute of Chemistry (joint meeting with the South East Essex Technical College Scientific Society, at the South East Technical College, Longbridge Road, Dagenham, Essex), at 7 p m —Mr D G Chisman "The Education and Training of Chemists"

Wednesday, October 21

Institution of Chemical Engineers (at the Geological Society, Burlington House, Piccadilly, London, W 1), at 5 30 p m —Mr K P Lanneau "Gas-solids Contacting in Fluidized Beds"

Institution of Mechanical Engineers, Steam Group (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Mr P Hamer "Present-day Feed-water Treatment for High-Pressure Boilers"

Royal Institute of Chemistry, London Section (at King's College, Strand, London, W C 2), at 6 30 p m —Dr D D Davies "Recent Advances in Plant Biochemistry"

Thursday, October 22

University College (in the Anatomy Theatre, Gower Street, London, W C 1), at 1 15 p m —Prof L S Penrose, F R S "Human Chromosomes" *

Physical Society, Optical Group (in the Science Museum Lecture Theatre, South Kensington, London, S W 7), at 2 p m —Discussion on the Stockholm Conference

University College (in the Eugenics Theatre, Gower Street, London, W C 1), at 5 p m —Dr B Cheng "Some Aspects of Space Law" *

Royal Society of Medicine, Experimental Medicine and Therapeutics Section (at 1 Wimpole Street, London, W 1), at 5 30 p m —Prof Sir Hans Krebs "Biochemical Aspects of Ketosis" (W E Dixon Memorial Lecture)

Illuminating Engineering Society (at the Institution of Civil Engineers, Great George Street, London, S W 1) at 6 p m —Dr W H Glanville, F R S "Light and Road Safety" (Golden Jubilee Lecture)

Institution of Mechanical Engineers, Hydraulics Group (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Discussion on "Effect of Cavitation in Hydraulic Machinery"

University of London (at Birkbeck College, Malet Street, London, W C 1), at 6 p m —Prof E G Boring (Harvard University) "The Genesis of Modern Psychology" (Second of three lectures on "The Pattern of Modern Psychology")*

Society of Chemical Industry (at the Royal Institution, 21 Albemarle Street, London, W 1), at 6 30 p m —Prof H Mark (U S A) 'Recent Progress in Polymer Chemistry" (Baekeland Memorial Lecture)

Oil and Colour Chemists' Association, London Section (joint meeting with the Oils and Fats Group of the Society of Chemical Industry, at the Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, London, W 1), at 7 p m —Dr W C Ault (Philadelphia) "Polymers and Plasticisers Derived from Fats"

Friday, October 23

Royal Institution (at 21 Albemarle Street, London, W 1), at 9 p m —Sir Norman Kipping "How Can We Help Underdeveloped Countries ?

Saturday, October 24

British Psychological Society (in the Gustav Tuck Theatre University College, Gower Street, London, W C 1), at 2 35 p m —Prof Edwin G Boring "The Role of the Zeitgeist in the History of Perception"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Research Assistant (with a special interest in electronics or fluid mechanics) for work in the Hydraulics Laboratory—The Professor of Civil Engineering, The Queen's University, Belfast (October 31)

Research Fellow in Physical Chemistry, for work involving the study of solids by physical methods including mass spectroscopy and positive ion bombardment—The Deputy Registrar, The University, Edgbaston, Birmingham 15 (October 31)

Senior Lecturer in Electrical Engineering at the University of Tasmania, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, October 31)

Senior Lecturer (with a special interest in ecology, plant physiology or genetics) in Agricultural Botany in the Department of Plant Science, Canterbury Agricultural College, University of New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (New Zealand, October 31)

Analyst (with a good honours degree in chemistry or its equivalent, and prepared to specialize in the analysis of rocks and minerals) in the Geology Department—The Professor of Geology, King's College, University of London, Strand, London, W C 2 (November 1)

Lecturer or Assistant Lecturer in the Department of Pharmacology—The Registrar, The University, Leeds 2 (November 4)

Lecturer in Physics, to undertake research in the field of metal physics or solid state physics (low temperature facilities are available) —Prof P M S Blackett, F R S , Physics Department, Imperial College of Science and Technology, London, S W 7 (November 9)

Lecturer in the Department of Physiology in the Faculty of Medicine, University College, Ibadan, Nigeria—The Secretary, Senate Committee on Colleges Overseas in Special Relation, University of London, Senate House, London, W C 1 (November 9)

Chair of Geology in the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (November 10)

Lecturer in Psychology at the University of New England, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, November 14)

Chair of Philosophy and Headship of the Department—The Registrar, The University, Nottingham (November 30)

Chair of Geography in the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (New Zealand, December 15)

MASS MEDIA OF COMMUNICATION AND SCIENTIFIC DEVELOPMENTS

IN his Rede Lecture, "The Two Cultures and the Scientific Revolution", Sir Charles Snow pointed out that a knowledge of science among the public was one of four essential conditions if Britain was to meet the challenge of the scientific revolution and, by seizing the opportunities that revolution offers, avoid a steep decline in our standard of living This knowledge was necessary not only for politicians and administrators but also for the whole community, who should know enough science to have a sense of what the scientists are doing This involves, as Sir John Cockcroft has pointed out, a definite effort to remove the language barrier between the public and the scientist, which makes it difficult even for those who are aware that science affects the life of the community to understand how science works and its implications for the community Sir John thought that in the everyday business of administration scientists had mostly succeeded in their effort to explain their work in plain language to politicians, Civil servants, diplomats and business men, but this is only a part of the problem of communication It is no less important that science should be better understood by the man in the street

This is in part a problem of formal education. Increasingly it is also a matter of using effectively the ways of communication at our disposal, and this means especially the mass media of the popular Press, sound broadcasting and television Only if wide and effective use is made of these media can we hope to keep the public sufficiently informed about scientific and technical advances for such discoveries to be put to either personal or public use, and, no less important, for the possibilities of abuse to be eliminated or minimized Nor is this entirely a matter of appropriate techniques or of the standard of public education We need to know much more about the way in which scientific information reaches the public and how much of it really penetrates to the public consciousness, and about the general attitudes, or even prejudices, regarding science and scientists which certainly exist in the minds of the public

These questions have been examined in a series of surveys sponsored by the National Association of Science Writers, Inc, of the United States (Five Longview Road, Port Washington, N Y), and although the reports relate strictly to the United States, their findings and conclusions are unlikely to be entirely invalid in Britain The surveys point to obstacles which exist no less in Britain than in the United States and they suggest ways in which communication could be improved here also, and dangers which threaten in differing degree rather than in differing kind Moreover, while a similar survey in Britain might not establish the existence of a large reservoir of interest in science reporting, with readers, listeners and viewers prepared to surrender other news and entertainment features to become better informed about science, it might well disclose the existence of sufficient interest to halt the present lowering of standards Indeed, failure to do so would provide a damning indictment of our educational system and point to an early decline to a third- or fourth-rate power

The first of these reports, "Science, the News and the Public", describes a sample survey of 1,919 American adults, selected to represent a cross-section of the public, conducted by the Survey Research Center, University of Michigan, and also sponsored by New York University, to ascertain who get what science news, where they get it and what they think about it The second report, "The Public Impact of Science in the Mass Media", describes a nation-wide survey conducted by the same Center and supported by a grant from the Rockefeller Foundation with the specific objectives of ascertaining the size and composition of the major mass media audiences, how science news fits into the news-reading patterns of the newspaper audience, and the conceptions and attitudes of the public relating to science and scientists, determining the size and characteristics of the science audiences of the media, describing the content of science news which has been read, heard and seen, obtaining the science audiences' evaluation of the way in which science news is presented, analysing the social and psychological factors that affect the consumption of science news, examining the effect of differential wording of science news items on the level of reader interest, and estimating the distribution of science information among the public This survey was based on a pilot study in 1955 of a non-random sample of 200 respondants The third report, "Satellites, Science and the Public", describing a national survey of the impact on the public of early satellite launchings, is a follow-up of the main survey It was conducted a year later, and it is focused on the changes revealed in the answers to questions regarding the Earth satellites put before and after the launching of the first satellite

The first report provides evidence that in the United States the mass media could reasonably increase the present cover of scientific developments, and it is argued that, with increasing numbers of students in high school and college, many of whom will be studying science, there should be a great expansion in the demand for science coverage in the channels of popular communication Much of the information in the mass media does reach the public mind, and on the evidence of this survey an impressive amount of this science information is retained The report once again directs attention to the room for improvement in the popular reporting of scientific developments, but beyond the observation that reporters and script-writers, given more training and time in assignments, would be able to provide more details, greater background, better interpretation and, possibly, higher accuracy, the report does not pursue this important theme It is conceded that such changes might help to correct present distortions in the public image of science and scientists and promote the idea that they are part of, not divorced from, contemporary living , but the conclusion stands that science is not constantly covered in the United States and that Americans lack information on which to decide intelligently public matters involving science, scientists, and possibly their own existence

These conclusions are substantially supported by the larger study Available evidence suggests that even allowing for a possible boom in science news stimulated by the launching of Earth satellites, the mass media are transmitting only a microscopic part of the supply of scientific information potentially available Since 76 per cent of the sample could recall one or more science items they had read or seen recently, 64 per cent recalling at least one item from the newspapers, 34 per cent from magazines, 13 per cent from radio and 41 per cent from television, it would seem that the demand has been greatly under-estimated

In the United States the mass media together cover all but 1 per cent of the private dwelling units of the country and at least a quarter or a third of every social category uses three media Papers appear to be the primary source of general views, and while the greatest change in the media used during the past decade has been the rapid spread of television, the written media have held their audiences well The combined science audience appears to include three out of four adults, and newspapers are the most important source of science news and radio the least Papers, magazines and television are mutually supplementary as sources of science news, but radio is weak both as a primary and secondary source Newspapers appear to take a key role in transmitting both science and medical news to this large science audience and there is generally a positive reaction towards science as it is presented in the mass media

The report then analyses in a separate chapter more particularly the newspaper audience, the magazine, radio and television audiences being considered in a following chapter While it is clear that science news is not read solely by the intellectual *élite*, the survey suggests that reading of non-medical science news is associated with a cosmopolitan and rather intellectual orientation towards news content, while medical news tends to be read by those with a more personalized local point of view Education and income-levels are reflected in science reading of both types and also in the extent to which actual news items are recalled Even in the social categories least prone to read science news, a sizeable minority is reached by the presentation of science in the Press

As regards magazines, the survey points to a relatively *élite* audience compared with the other media, and in general magazine readers of science in the United States appear to be highly satisfied with the way their medium presents science The newspaper is the most important supplementary medium for these readers The radio audience of science, however, appears to be scanty, and although the audience is spread very evenly through the population, the completeness and accuracy of science news on the radio receive adverse comment Again, the newspapers provide much supplementary information for this group Television has not yet challenged the lead of the newspaper, and its potentialities for the transmission of science news are regarded as largely unexplored, but there is evidence in this report that a good deal of care will be required in developing this field if science information is to be presented without exaggeration and distortion

Subsequent chapters consider briefly the forms and channels in which science news is presented in relation to effective presentation, but the data are too scanty for more than tentative evaluations of presentation to be made The evidence indicates that additional interest is more readily stimulated the more a person is already interested in science, but nevertheless more vivid or stimulating presentation does affect those who are not already interested or trained in science Education in science is, however, important as providing both the necessary background and a sensitivity to scientific topics The evidence presented in this report fully supports the argument that sufficient general science should be a part of the education of every citizen to enable him or her to understand how science works, what it is about and something of its meaning in the world to-day

This factor can obviously determine attention or indifference to science news and the report seeks to analyse these motives Most of those interviewed were willing to have other news cut to get more science news in the papers, but the reasons for interest in science most cited were fairly broad, and orientation to science seemed to serve the broader functions of making sense of the world and helping to manage one's relations to it This, of course, indicates the importance of presenting science in its context and not presenting pieces of information or facts in isolation

Finally, the survey examines the current attitudes to science and the world which go so far to determine the public understanding or misunderstanding of science as it is presented to them to-day When asked to strike a balance of the effects of science on the world the public overwhelmingly stresses the good effects These are seen primarily as improvements in health, standard of living and technological advance, and the direct ill-effects on the world are seen almost entirely in terms of the destructive potential of nuclear energy Concern about the detrimental effects of science on the social order and the deviating traits of scientists was an underlying theme, and the report, besides noting that people who are highly concerned about such issues are likely to advocate limiting scientific research, points out that in times of crisis these ambivalent attitudes could lead to a more negative picture of science.

The report on the survey of the public impact of early satellite launchings shows that almost half the adult population of the United States became aware of the satellites in a single year. 90 per cent had heard of the satellites by mid-1958 compared with less than 50 per cent a year earlier. Less than one-third of those aware of the satellites thought of them as having primarily an immediate scientific purpose; about one-fourth knew of no purpose. Both awareness of the satellites and of their scientific purpose was related to the education, income and number of media used by the person, and the evaluation of science and scientists was overwhelmingly favourable in both these comparative surveys. Within the newspaper audience there was a moderate increase in readership of science.

The comparative survey provides further evidence that awareness of a scientific event or finding can be stimulated in all strata of the public if enough news concerning the event can be made available to the audience, and that it is probable the public reaction to a scientific event is largely determined by a desire to understand and master the world as seen by the individual. Increase of interest in a particular area of science due to a major break-through in knowledge or achievement is unlikely to stimulate interest in other scientific areas unless the public sees definite links between the areas. The pattern of public reactions to science and scientists is a complex and pervasive phenomenon, and the generally favourable attitude to science and scientists is regarded as more stable than the public's notions of the boundaries of scientific endeavour. Science and scientific events, however, do not operate in a vacuum and some aspects of the public's evaluation of science are liable to change. It seems likely that the public is less concerned with what science is than with what it accomplishes.

These generalizations are scarcely new to the scientific writer and are indeed part of the everyday technique of communication. On the actual technique of communication, however, these reports throw little light. They are of interest to British readers rather for the attention they direct to certain dangers as well as to trends and objectives in the use of mass media and perhaps especially to the fundamental importance of education. They underline, indeed, the importance of the investigation of the educational potentialities of the mass media on which Mr. J. Trenaman has been engaged for the past three years with the support of the Nuffield Foundation, and provide substantial evidence that effective use cannot be made of the mass media, and perhaps especially of television, if our educational system is defective. Shortcomings there will not be remedied by the mass media.

Indeed, if one generalization is to be drawn from these reports, it is that the mass media are unlikely to prove a reliable method of increasing the public understanding of science unless the mass audience has itself already been prepared by its general formal education to understand what science is about and the place it takes in the world to-day. Without this the dangers of abuse, particularly of broadcasting and television, to which renewed attention was directed in the debate in the House of Lords on June 3, and by Mr. H. Carleton Greene, the recently appointed director-general of the British Broadcasting Corporation, in an address* to German business men on April 18, and by Dr. M. Conran in his article on the Third Programme, will remain formidable. There is little in the American survey to suggest that Field-Marshal Smuts was unduly pessimistic in regarding the disappearance of the sturdy, independent-minded, freedom-loving individual and his replacement by a servile, standardized, mass-mentality as the greatest human menace of our time. Indeed, it is almost inherently impossible for the mass media themselves to check this process. Lord James of Rusholme in the Lords debate remarked that one cannot use all the techniques of mass persuasion, appeal consistently to the facile, the uncritical and the escapist, and still talk of freedom.

The debate in the House of Lords did not resolve this issue. It focused attention rather upon the question of public responsibility, and strong support was forthcoming for the view that television, as well as sound broadcasting, should be made entirely responsive to the public interest and, whether in the public or in the private sector, subject to impartial review. Lord James was forthright on the importance of this sense of public responsibility and of television and broadcasting being independent of any political or commercial pressure, so that new facilities could be freely used and in new ways if we are to foster an educated democracy, as critical, as knowledgeable and as free as we can make it.

There was little support in the debate for further extension of television programmes but some for the improvement of programmes and for technical research. Lord Hailsham seemed to stand alone in his reply for the Government in professing satisfaction with the present position and no concern about the possibility of abuse or debasement of standards. This was Mr. Carleton Greene's main concern, however, and, arguing that radio and television are too powerful in the potential long-term effects for their control to be entrusted to either politicians or business men, he points out that once the fairness and impartiality of a broadcasting system become suspect its authority as a source of information is destroyed. He quotes American experience to show how liable this is to happen in commercial television, and he suggests further that available evidence points to the conclusion that commercially controlled broadcasting tends, in the long run, to undermine the intelligence, at any rate, of its constant listeners and viewers, and makes it more difficult for them to appreciate programmes which demand some thought and application. It makes them passive rather than active.

This can be particularly serious for children, and the possibility is the more disturbing in that the American survey confirms so strongly the determining influence of early education brought out in Mr Trenaman's study The most powerful influence in effective communication is the full-time education received in childhood and early youth , and alike in resisting the detrimental or anti-social influences of broadcasting or in realizing the potentialities of these new media for adult education this is the decisive factor It far outweighs the importance of technical improvements in the use of television or sound broadcasting for educational purposes, and though Mr Greene's address at first sight seems to bear only indirectly on the American inquiry, it should be clear that any attempt to improve the use of the mass media to disseminate scientific information and advance the public understanding of science could well fail if it did not take account of this factor, and if it ignored the consequences of political and sectional pressure debasing the media

---

* Two Threats to Broadcasting: Political and Commercial Control. By H. Carleton Greene. Pp. 8. (London: British Broadcasting Corporation, 1959.)

Mr Greene does not ignore the beneficial results which a public service broadcasting system can bring and he points out that B B C television has, contrary to expectation, had in England a favourable effect on reading habits rather than otherwise The use of radio and television in schools, however, is quite a separate issue What needs to be emphasized first is the crucial importance of an adequate system of education in the schools if the level of public understanding of science is to be raised That comes first, and no improvements in the techniques of presentation and of using the mass media can compensate for shortcomings there Further, with the realization of the opportunities which television and also sound broadcasting should increasingly offer, if wisely used, for communicating scientific information, there should be a keen appreciation of the irreparable damage that can be done both to the reputation and effectiveness of the medium and to public intelligence if these media are rashly and irresponsibly used

EGYPT AND GREECE IN MEDICAL HISTORY

Ancient Egyptian and Cnidian Medicine

The Relationship of Their Aetiological Concepts of Disease By Robert O Steuer and J B de C M Saunders Pp xii+90 (Berkeley and Los Angeles University of California Press , London Cambridge University Press, 1959) 22*s* 6*d* net

THE authors of this interesting and constructive, though highly specialized, book introduce the problem which they seek to expound by the statement that "throughout the history of medicine the physician has searched for a theory of disease through which he might organize a diversity of data and thus justify his practice by establishing a scientific system" This is an elaborate way of saying that for centuries doctors have been looking for an easy way of practising by rule-of-thumb Even in ancient Egypt this search had begun, although many medical historians have regarded the contribution of Egypt to modern medicine as negligible, because it was magico-religious, and entirely devoid of any rational approach The recent re-examination of the existing medical papyri has placed Egyptian medicine in quite a different category, and has confirmed the view, previously advanced with little supporting evidence, that the Greeks, acknowledged to be the first to base their medical practice upon observation rather than upon theory, drew many of their ideas from the Egyptians The first to profit from the Egyptian impact was the pre-Hippocratic School of Cnidos (on the mainland opposite the island of Cos) Cnidian medicine, however, was apt to confuse symptoms with diseases, and it was not until Hippocrates of Cos insisted upon the need for observation, and upon the importance of prognosis rather than diagnosis, that the great era of Greek medicine was inaugurated

The present work deals with the link between Egypt and Cnidos Both were preoccupied with the idea of putrefaction as a cause of disease, and with the means of preventing it The prevention of corruption had been carried to a fine art by those who embalmed the human body after death, and this process of mummification was based upon the principle which was followed also by those who sought to heal the living body by getting rid of putrefaction within it It was alleged that disease was caused by the *materia peccans* in the fæcal content of the bowel It logically followed that treatment must consist of eliminating the noxious agent or putrefying matter by purgatives or enemata

The writers of the book under review give many examples of this etiological concept, culled from various papyri, especially the "Papyrus Anonymous Londinensis", besides a number of Greek writings Although the Cnidian notions appear to have been supplanted by the idea of the humours, favoured by Hippocrates and the Coan School, the two opinions were to some extent united when it was admitted that even the humours might be corrupt or putrefying This idea paved the way for the doctrine of the ethereal 'miasma' as a cause of disease, an idea which held the field for centuries in various guises until at length the pathogenic nature of bacteria was demonstrated The relationship between the ideas of Egypt and those of Greece is a significant chapter in the history of medicine, and Dr Steuer and Prof Saunders are to be congratulated on their careful and well-documented study of the putrefactive principle in ancient writings Besides the 55 pages of text, there are an appendix expounding the views of Galen on the matter, and another, suggesting that air-borne disease may have been envisaged even in ancient Egypt There are twelve pages of informative notes and a bibliography, as well as an adequate index

DOUGLAS GUTHRIE

THE MOVING FRONT OF CARBOHYDRATES

Advances in Carbohydrate Chemistry, Vol 13

Edited by Melville L Wolfrom in association with R Stuart Tipson Pp xi+387 (New York Academic Press, Inc , London · Academic Books, Ltd , 1958) 88*s*

VOL 13 of "Advances in Carbohydrate Chemistry ' presents ten reviews on specialized topics of carbohydrate chemistry Trends of present-day sugar chemistry are reflected in the titles of some contributions and are interwoven in the text of others Interest in amino-sugars has grown considerably over the past two decades with the recognition that biologically active mucopolysaccharides and mucoproteins such as heparin, blood group specific substances, virus hæmagglutinin inhibitors and gonadotropins contained N-substituted 2-amino-2-deoxy sugars Furthermore, sialic acids, containing as nucleus an amino-sugar, have established themselves as regular components of mucoproteins and some mucolipids of animal origin and as constituents of the membrane of certain bacteria Interest in the impact of alkali on simple sugars, oligosaccharides and polysaccharides has been revived by the discovery of enzymes catalysing aldose – ketose isomerizations, by the realization that the glycosides of β-hydroxyaldehydes and β-hydroxyketones are sensitive to alkalis and by the recognition that the products of alkali degradation of polysaccharides afford valuable information as to the linkage of the constituent units Finally, the problem of the conformation of the individual sugars enters into nearly every discussion on the reactivity of the carbohydrate concerned

The topic of sugar-ring conformational analysis attended to in previous volumes is extended by F Shafizadeh to the formation and cleavage of the oxygen ring in sugars· Shafizadeh discusses various aspects of the interconversion of the cyclic forms and acyclic forms of a sugar The inductive effect of the hydroxyl groups on the reactive function and the steric effects are well exemplified The nitrous acid deamination of amino-sugars provides further proof of the profound effect the nature of the adjacent group and the configuration and conformation of the molecule have on the reaction A concise summary of the preparation and physical properties of the methyl ethers of D- and L-glucosamine, D-galactosamine, D-allosamine and D-altrosamine is provided by R W Jeanloz, who has made many contributions to this field The availability of these ethers renders it possible to apply the methylation procedure of structural analysis to oligo- and poly-saccharides containing amino-sugars

In the chapter on sialic acids, F Zilliken and M W Whitehouse give a useful account of the composition, structure, determination and distribution of the various sialic acids (N-acylated neuraminic acids) The presentation would have gained in appeal if the authors had stressed the unique arrangement of the functional groups in neuraminic acid (the common parent compound) and interpreted the remarkable properties of this group of substances on the basis of this arrangement With regard to the linkage of sialic acid in animal mucoproteins it is safe to say that the acid is invariably found as a terminal unit , it seems improbable that it serves as "a chemical bridge between polypeptides and polysaccharides" (p 238) There is no evidence that the influenza-virus particle has any other enzymic activity than that of an α-neuraminidase (see p 260) Perhaps I may be allowed to point out that the molecular structure of neuraminic acid, proposed in 1955, was conceived not so much on speculation as on the hard facts that N-acetylneuraminic acid was convertible under mildest alkaline conditions to pyrrole-2-carboxylic acid and that the same pyrrole was obtained by aldol condensation of D-glucosamine with pyruvic acid These findings (*Nature*, **176**, 881 , 1955) left no doubt on the position in neuraminic acid of the key functional groups and favoured Blix's (1955) rather than Zilliken's (1955) empirical formula of N-acetylneuraminic acid

The Lobry de Bruyn – van Ekenstein transformation of sugars in all its aspects and side-reactions (formation of deoxyosones) is very logically presented by J C Speck The accumulated results show that these transformations proceed by an enolization type of mechanism and that a common intermediate is formed in the aldose – ketose isomerization and the 3-deoxyosone production The alkaline degradation of polysaccharides also begins at the reducing end of the molecule with enolization and proceeds stepwise through the anhydroglycose chain In such a peeling process the reducing end group is liberated from the chain by elimination of the rest of the chain as a glycoxy anion The released end-group forms an α-dicarbonyl structure which is rearranged by a Cannizzaro type of reaction to yield saccharinates R L Whistler and J N BeMiller have cogently summarized this field The reaction schemes clearly indicate the dependence of the type of saccharinate formed (ordinary, meta- or iso-saccharinate) on the structure of the glycosyl units of the polysaccharide. Incidentally, treatment of unsubstituted N-acetyl-D-glucosamine by mild alkali results in the formation of D(+)-5-dihydroxyethyl-3-acetamido-furan, and not in that of glucoxazoline (p 305) The life-work of J W E Glattfeld on four-carbon saccharinic acids is reviewed by J D Crum

The story by G V Caesar of starch nitrate, the oldest known and industrially the most important starch derivative, reads like a 'thriller' I Goodman reports on glycosyl ureides and L Stoloff contributes a chapter on polysaccharide hydrocolloids of commerce The important formazon reaction with its implications for the structure of sugar phenylhydrazones and phenylosazones and with its use as a tool for elucidating the structure of polysaccharides is comprehensively described by L Mester

It seems most appropriate that the opening chapter is dedicated to the memory of Carl Neuberg, who has made outstanding contributions to many of the topics discussed in this excellent volume

ALFRED GOTTSCHALK

PRELUDE TO SPACE RESEARCH

Vistas in Astronautics

First Annual Air Force Office of Scientific Research Astronautics Symposium (Co-sponsored with Convair Division, General Dynamics Corporation) Edited by Morton Alperin and Marvin Stern (International Series of Monographs on Aeronautical Sciences and Space Flight Division 7 Astronautics Division, Vol 1) Pp xxi+330 (London and New York Pergamon Press, 1958) 105*s* net

IN February 1957 satellites and space exploration were things of the future, and the organizers of the Astronautics Symposium held in that month at San Diego were at pains to secure serious papers on the subject from recognized scientists, rather than to encourage speculative contributions Consequently, the title of this book, which provides a record of the papers read at the Symposium, is slightly misleading most of the papers remain earthbound (if we stretch this phrase to include satellite orbits) , only a few flutter off into the depths of space

The book is divided into six sections of roughly equal length The first, entitled "Re-entry", includes an excellent paper by C Gazley describing the deceleration and heating of a body entering a planetary atmosphere from space, and several contributions on the aerodynamics of re-entering space-vehicles

Part 2, on "Tracking and Communication", includes a detailed description of the 'Microlock' radio instrumentation system for satellites The third section, on the environment of a space vehicle, has several expert surveys of particular topics, such as F L Whipple's paper on the "Meteoric Risk to Space Vehicles" and H V Neher's terse 1½ pages on cosmic rays In Part 4 the possible propulsion systems for space travel are fully discussed Part 5 is devoted to orbits, and includes a 39-page paper by H Oberth, on "A Precise Attitude Control for Artificial Satellites" Part 6 is entitled "Human Factors", and covers space medicine and legal problems

The individual papers in the volume differ greatly in their length, tone, technicality and worth The book can be recommended for its many good technical papers, most of which have stood the test of time well, but there are a few half-page contributions which scarcely deserve permanent reproduction in book form, and the frontispiece, a full-page photograph of the brigadier-general commanding the Air Force Office of Scientific Research, seems rather out of place in a technical book. D. G. King-Hele

EXPLOSIONS IN SOLIDS

Fast Reactions in Solids

By F P Bowden and A D Yoffe Pp ix+164 (London Butterworths Scientific Publications, New York Academic Press, Inc, 1958) 40*s*, 7 dollars

THIS book is a sequel to the authors' earlier (1952) monograph "The Initiation and Growth of Explosion in Liquids and Solids" It deals with subsequent work on the same problems and more particularly with the mechanism by which a crystalline explosive decomposes when subjected to heat, light shock or nuclear radiation Like its predecessor, the book does not attempt to give a comprehensive treatment of the whole field but rather to focus attention on salient developments in the study of explosives and especially on those areas to which the work of the authors and their colleagues has contributed In this it is most successful and it is a stimulating and attractive volume

Chapter 1 is a brief (4 pages) introduction and sketches the plan of the book Chapter 2, which gives an account (13 pages) of the slow decomposition of crystals, is based mainly on silver azide Chapter 3 is longer (25 pages) and more diversified Under the general title of thermal explosions it gathers a varied, though not always clearly organized and interrelated, collection of theory, simple calculation and experiment It is an important chapter to the remainder of the book, for the ideas of thermal explosion theory outlined here are repeatedly applied in this and subsequent chapters The importance of a molten zone to reaction propagation is also introduced In Chapter 4, the structure and stability of the inorganic azides are reviewed (12 pages) in terms of electron sharing between the metal atom and the azide group, this concept is one of the important new points of view this book adopts Chapter 5 (31 pages) on initiation of explosion by shock is closest in theme to the previous monograph An account is given of recent work on initiation by impact, flying particles and shock waves, by friction and by ultrasonic vibration Mechanical initiation is thermal in origin, but 'mechanical' factors such as the disintegration of liquids and solids play a part Chapter 6 (25 pages) reaches a basically similar conclusion about initiation of explosion by flash photolysis The azides are again the principal subject and the concepts of Chapters 3 and 4 are applied in interpretation Decomposition and ignition by nuclear particles and high-energy radiations are dealt with in Chapter 7 (11 pages) High-energy particles provide a convenient method of introducing large amounts of energy into molecularly small regions of the crystals, and the experimental evidence so far is that the activation of a small number of adjacent molecules may not be enough to cause explosion In Chapter 8 (7 pages) the mysterious, spontaneous explosions which occur during crystallization of lead and mercurous azide are described and discussed The first part (7 pages) of Chapter 9 on the fast growth of explosion deals with thin films and the deflagrations and "low velocity detonations" which occur The second part (9 pages), which contains some very striking photographic records, discusses small single crystals undergoing explosive decomposition

This is the arrangement of the text Each chapter after the first has its own 'conclusion' summarizing in broad generality the trends the authors feel significant and it is often helpful to read these before their chapters Perhaps the reader would have been helped still more had the principal subdivisions of the chapters been listed with the contents The text is prefaced by a useful list of names and formulæ of most of the explosives discussed and followed by a set of eight appendixes which are up-to-date short tables of various properties There are good author and subject indexes

It is not the duty of a monograph of this nature which concentrates on recent work in a changing field to supply an extensive background, the appearance last year of M A Cook's formidable "Science of High Explosives" helps to meet this need This book is modern and reliable and the few errors other than trivial misprints that exist, such as the apparent application of le Chatelier's principle to a non-equilibrium process, the occasional use of 'inorganic compound' where 'ionic solid' is intended and of the erroneous $Cu_2(N_3)_2$ and $Au_2(N_3)_2$, may arise from compression and from production of such an up-to-date monograph Above all, the experimental work from the authors' laboratory has a lucid quality which permits it to speak for itself without laborious argument Perhaps 'photogenic' is an apter word to do greater justice to the brilliant photographs which have been obtained and which so admirably illustrate the text Peter Gray

APPLICATIONS OF STATISTICS IN PHYSICS

Statistical Physics

By L D Landau and E M Lifshitz (Course of Theoretical Physics, Vol 5) Translated from the Russian by E Peierls and R F Peierls Pp x+484 (London Pergamon Press, Ltd, 1958) 80*s* net

IN abandoning the general practice of considering classical statistics, quantum statistics and thermodynamics as virtually separate subjects, the authors have produced a book in which the three have been combined with considerable success Although no concessions have been made to the mathematically under-privileged, the importance and significance of the underlying physical principles have not been neglected so that the honours degree student, irrespective of his mathematical attainment, will find much to stimulate his interest in, and to clarify his ideas on, this the most fundamental branch of physics

The initial chapters are devoted to the establishment of general principles by first laying the statistical foundations, then deriving the principal thermodynamic quantities and relations associated with the macroscopic state and finally obtaining the standard distribution functions, both classical and quantum Then follow admirable comprehensive treatments of particular applications to closed systems in thermodynamic equilibrium, some examples of which are perfect and real gases, condensed bodies, solutions, chemical reactions, fluctuations and surface phenomena A chapter on the symmetry of macroscopic bodies could well be omitted as the treatment is too condensed for all but professional crystallographers, and for them it is unnecessary

There are some weaknesses in the general presentation The style is occasionally laboured and an improvement in the continuity could be effected by including in the text the material added in numerous footnotes Further, it is surely unnecessary to derive first a dimensionless expression for entropy into which later must be inserted Boltzmann's constant Again, after the excellent exposition of the basic statistical principles it is surprising that reference should be made to both the specific heat and the Gibbs free energy per molecule Finally, the authors depart in several instances from the conventional in their use of thermodynamic terms , in particular, by "adiabatic" they always mean "reversible adiabatic"

H Steeple

THE GREAT LAKES

Geology of the Great Lakes

By Prof Jack L Hough Pp xviii+313 (Urbana, Ill University of Illinois Press, 1958) 8 50 dollars

FORTY-FOUR years have passed since Leverett and Taylor published their classic work on the history of the Great Lakes During much of the last twenty-seven of these Prof Hough has been engaged on studies of the various aspects of this great group of inland waters There has been a growing need for a summary of the large amount of work that has been accomplished in the interval

The book is divided into two parts The first deals with the topography and hydrology of the present lakes and the deposits on their floors, as well as the pre-glacial and glacial history of the region in general terms The latter is inevitably a simple outline which forms the basis for the more important second part of the book

Part 2, comprising rather more than half the book, deals with the history of the stages of evolution of the lakes as bodies of open water fluctuating in extent, with changes in the position of the oscillating front of the ice sheet to the north The series of outlets of the lakes to the Mississippi, to the Mohawk and Hudson valley, to Lake Erie and the St Lawrence, and to the St Lawrence via the north-east corner of Lake Huron and the Ottawa River came into action repeatedly The story now unfolded is substantially more complicated than the account of Leverett and Taylor, and the work is very much better documented, in consequence of the research by many workers, including substantial contributions from the author himself This applies particularly to revised and more detailed correlation of events over the vast area involved

Particularly noteworthy parts of the book are the detailed but concise critical assessments of the evidence on which correlation is based, a valuable correlation chart based with an absolute dating scale on carbon-14 measurements, and among the many text figures 23 diagrams, summaries of the successive stages in the fluctuation of the extent and outlets of the lakes throughout late and post-glacial time The large-scale southerly tilt of the area consequent on the isostatic rise as a result of the progressive de-glaciation of the area introduces complications in the history in the correlation of shore lines, and this is accentuated by the erosion of considerable lengths of the old beaches during later stages of the history of the lakes

The author is to be congratulated on a major contribution to late-glacial geology of the region The text figures are clearly produced and there is an excellent bibliography

S E Hollingworth

ANTING

Phoenix Re-born

By Dr Maurice Burton Pp 224+16 plates (London Hutchinson and Co (Publishers), Ltd , 1959) 25*s* net

FOR many years anting in birds has held considerable fascination for students of bird behaviour So, too, has the mvth of the Phœnix, and when Maurice Burton saw a tame rook disporting himself on a heap of burning straw it led to an association of ideas which was ultimately responsible for the production of this book After thorough exploration of the Phœnix legend, Burton carried out experiments with his tame rooks and a pet jay to determine their reactions to certain substances and to heat He also examined the literature to see whether records of bird and other animal behaviour might reveal anting incidents which had been unidentified Eventually Burton reached certain conclusions which show a clear connexion between Herodotus's account of the Phœnix and the anting of birds

One thing is common to all the substances which cause the anting posture this is heat or the impression of heat In this remarkable book Burton compares the reaction of birds to different substances, examines the theories of anting and comes to the conclusion that anting must be regarded as a posture adopted in moments of unusually intense excitement This may be stimulated autochothonously or through the agency of an external stimulus producing heat or the impression of heat in the mouth Ant-bathing and thermophily are also shown to be closely related to anting proper and all these are related to such habits as the self-anointing of hedgehogs, the effects of catmint and other odorants on carnivores, as well as numerous idiosyncrasies of behaviour among individual birds and mammals, not excluding man himself

The charm of the book lies not only in the emergence of a new theory to an old puzzle , the telling also stamps "Phœnix re-born" as an ornithological thriller of outstanding interest

T H Hawkins

Introduction to Functional Analysis

By Prof Angus E Taylor Pp xvi+423 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd , 1958) 100*s* net

LINEAR functional analysis arose partly from Hilbert's theory of space of an infinity of dimensions and its axiomatic formulation by John von Neumann, and partly from Banach's development of Fréchet's work on abstract spaces Good recent books include those by Zaanen and by Riesz and Nagy Prof Taylor's introduction will not displace these books, but can serve as a useful survey of basic methods In lecture form, the material has been tried out on several graduate courses in the United States, and hence is particularly helpful in the early chapters In the first, the algebraic formulation is kept clear of topology , linear spaces, operators and functionals are defined and illustrated by a wealth of examples of each type, so that the novice is gently helped to surmount his initial difficulty of forming some concrete idea of these abstract concepts The second chapter is a reference section on topology , then in the third, the linear space and the topological space are related to provide the concept of the linear topological space, again with many carefully detailed instances of such spaces The reader who studies these three chapters closely will be rewarded with a firm grasp of fundamentals and should then cope readily with the somewhat increased pace of the later chapters giving the general theory of linear operators, spectral analysis and the standard results for self-adjoint, normal and unitary operators The old-fashioned analyst will be pleased to see contour integration employed in the spectral theory, a method much emphasized in some of Taylor's own papers The final chapter, on integration and linear functionals, is intentionally only a sign-post to further reading in this field The book should be particularly valuable to those who need to get some knowledge of the unifying and co-ordinating power of this potent theory without having to make a specialist's study of it T A A BROADBENT

The Birds of the Palearctic Fauna

A Systematic Reference Order Passeriformes By Dr Charles Vaurie Pp xii+762 (London H F and G Witherby, Ltd , 1959) 105*s*

IT has been claimed that birds are systematically better known than any other class of animals, but even for the relatively familiar Palæarctic region a new 'base-line' has become desirable This is here provided in respect of the passerine birds—a second volume is now being prepared to cover the rest—in succession to the corresponding part of Hartert's "Die Vogel der palaarktischen Fauna" of 1903–32 Unlike Hartert, the present author does not give descriptions of species, but only the main points distinguishing one sub-specific form from another , synonymies are brought up to date rather than repeated in full English names are given for all species, with the French and German equivalents where these exist

The present less-rigid outlook on intraspecific systematics is reflected in the emphasis placed on the 'clinal' nature of much of the geographical variation, and previously described races which the author regards as mere stages on a cline or as otherwise unsatisfactory are relegated to the synonymy , races which the author accepts are graded as "well" and "moderately well" differentiated but are otherwise given identical treatment Of special value are the detailed accounts of the ranges of all forms, and these are usefully reinforced by information about the habitat of each species There are also brief indications of extra-limital distribution and of the existence of extra-limital races, the latter being mentioned by name when not too numerous There are doubtless some points on which other experts may differ, but the volume can be welcomed as an up-to-date authoritative work of reference on the systematics and zoogeography of the palæarctic passerine avifauna LANDSBOROUGH THOMSON

The Open Sea—Its Natural History

Part 2 Fish and Fisheries, with Chapters on Whales, Turtles and Animals of the Sea Floor By Sir Alister Hardy (The New Naturalist a Survey of British Natural History) Pp xiv+322+48 plates (London William Collins, Sons and Co , Ltd , 1959) 30*s* net

THOSE who enjoyed Sir Alister Hardy's first book on "The Open Sea" will also enjoy his second, for it has the same virtues it is written with infectious enthusiasm and with a wide knowledge of fish and fishermen He has sailed in both the old and the new *Discovery*, in trawlers on fishing trips and in fisheries research vessels of many lands, so that he brings a vivid sense of actuality into his writing

Beginning with a brief résumé of the fundamentals of life in the sea, the author goes on to describe what a fish is and how it lives and moves Then follow chapters on particular fish and fisheries The herring is given pride of place with a short account of its history and of the research work on it right up to the present day After two chapters on the bottom fauna, we return to fishing with descriptions of different types of gear and chapters on plaice, elasmobranchs and gadoids The over-fishing problem is not neglected, and indeed in many places throughout the book the author shows how the knowledge we already have could be applied to improve or increase the fisheries He ends with the plea that the division of the North Sea into northern and southern spheres of research should be abandoned in favour of a united effort covering the whole area

There are chapters also on the animals of the ocean floor, on parasites, particularly of fish, on reptiles (not omitting the sea-serpent) and on marine mammals

No attempt has been made to cover the systematics or physiology of fish This is a natural history of the creatures living in the open seas around Britain and there can be few who will read it without learning something new and interesting

Mention must be made of the excellent illustrations Many of the plates are reproductions of the author's own delightful water colours The photographs many by Dr D P Wilson, are outstanding and include some wonderful shots of whales and courting fish S M MARSHALL

Flora of Peru

By Rogers McVaugh (Field Museum of Natural History Botanical Series, Vol 13, Part 4, No 2) Pp ii+569–818 (Chicago Field Museum of Natural History, 1958) 3 75 dollars

THIS part continues the Flora of Peru with the account of the difficult family, Myrtaceae, contributed by Prof Rogers McVaugh, of the University of Michigan The bulk of the species belongs to two large genera, *Myrcia* and *Eugenia* The author is to be congratulated on his carefully prepared keys and long specific descriptions There are no illustrations

SPECTROSCOPIC IDENTIFICATION OF ALPHA-EMITTING NUCLIDES IN BIOLOGICAL MATERIAL

By Prof W. V. MAYNEORD, C.B.E., and C. R. HILL

Physics Department, Institute of Cancer Research . Royal Cancer Hospital,
London, S W 3

IN connexion with a programme aimed at the identification and measurement of the radioactivity of the human body and its environment[1-4], an attempt has recently been made to undertake spectral analysis of the alpha-activity of normal biological materials The most satisfactory general method of analysing alpha-activity is to measure the size of the individual pulses due to electrons which are produced when the alpha-particles are made to spend their full energy on ionizing a free electron gas In the past, attention has been directed largely to materials having moderately high specific activity and the gridded parallel plate ionization chamber has been the instrument most commonly used[5-8] This type of chamber is not, however, suitable for the analysis of materials of very low activity, for which a large source area and a low background counting-rate are essential In order to provide a large source area, Lonati *et al* have designed an instrument in which the source material is spread on a large metal sheet, which is afterwards rolled to form the outer member of a cylindrical electrode system, a grid being situated between the emitter and collector[9] The background counting-rate of their instrument is still appreciable and due, in part at least, to the large areas of metal surface exposed to the counting volume, and to contamination on the grid wires The use of a cylindrical or spherical arrangement can, however, largely obviate the need for a grid in overcoming line broadening due to positive ion effect[10] and has been exploited successfully by Ghiorso in an early instrument[11] If, in a gridless chamber, the sensitive volume is surrounded by material having very low alpha emission, the background counting-rate corresponding to alpha-particle energies may be made very small Such an instrument has been built by us at the Institute of Cancer Research Royal Cancer Hospital and has proved to be capable of analysing the alpha-activity of a wide range of normal biological materials

Description and Performance of the Instrument

The instrument consists essentially of two concentric cylindrical electrodes of length 53 cm and radii 15 and 0 2 cm , respectively The material to be analysed is mounted on the metallized surface of a sheet of aluminized cellulose acetate, lining the inner surface of the outer electrode, and a potential of minus 3 kV applied relative to the inner, collecting electrode The electrode system is enclosed in a vacuum-tight steel tank containing a mixture of 90 per cent argon and 10 per cent methane at atmospheric pressure Under these conditions the theoretical spectral line-width due to positive ion effect is 210 keV at 5 5 MeV The line-width obtained in practice is rather greater as a result of contributions from amplifier noise and self-absorption in the uncollimated source As a result of mounting the source on aluminized cellulose acetate film (which itself has a surface emission of about 3 alpha-particles per hr per 1,000 cm^2 compared to stainless steel 100, brass 100, aluminium 150) and of the relatively small area of other surfaces exposed to the counting volume, the background counting-rate due to surface emission is only 20 counts per hr in the energy-range 4–9 MeV and for a useful source area of 4,000 cm^2. Due, however, to the presence of radon, originating, it is believed, mainly from the surface of the pressure vessel (which was originally built for another purpose and is impossible to clean satisfactorily), the actual background is somewhat higher than the above figure By continuously circulating the chamber gas over charcoal cooled in a solid carbon dioxide–alcohol bath, the radon background, which appears as a three-line spectrum of radon, radium A and radium C′. is maintained constant at 70 counts per hr , giving a total background of 90 counts per hr

The ionization chamber is used with *EKCO* 1049 *B* head and main amplifiers and a *CDC* 100-channel pulse-height analyser This combination provides good stability of recording and, when purity of the chamber gas is maintained by continuously flowing over calcium turnings at 350° C , overall drift can be kept within 100 keV over a period of several days

Preparation of Sources

The sources, which normally consist of a partially insoluble ash of uncertain chemical composition, are prepared by grinding (by hand or in a ball mill) followed by spraying in the form of a suspension in water on to the cellulose acetate sheet, previously wetted with dilute 'Teepol' solution A thin layer of sodium silicate solution is usually sprayed on top of the film so formed (0 03 mgm /cm^2 sodium silicate) to act as an adhesive[12] By this process it is possible to prepare sources which under a microscope appear to consist mainly of particles of about one micron diameter, spread with good uniformity

Results

As illustrations of the use of this technique, spectra obtained with our equipment are shown in Figs 1–4

A popular breakfast cereal, stated to contain "100 per cent whole wheat" and having a total specific alpha-activity of 32 × 10^{-12} c per gm of ash (Fig 1), evidently contains two long-lived alpha-emitters, radium-226 and thorium-228 (RdTh), and their daughters Most of the radon-222 escapes from the thin source and is removed from the system by the radon trap, so that it and its daughters do not appear

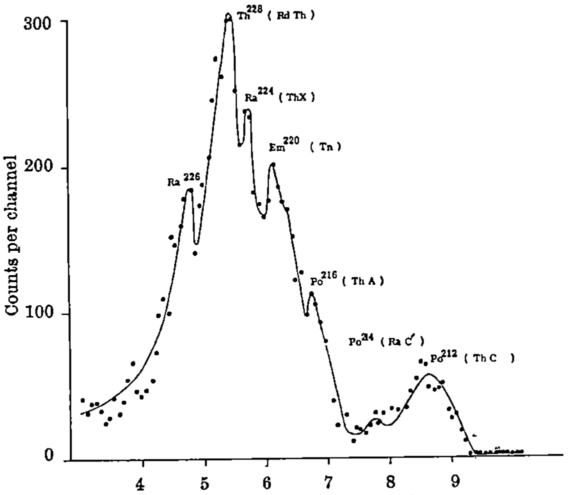

Fig 1 A breakfast food '100 per cent whole wheat' Counting time 24 hr

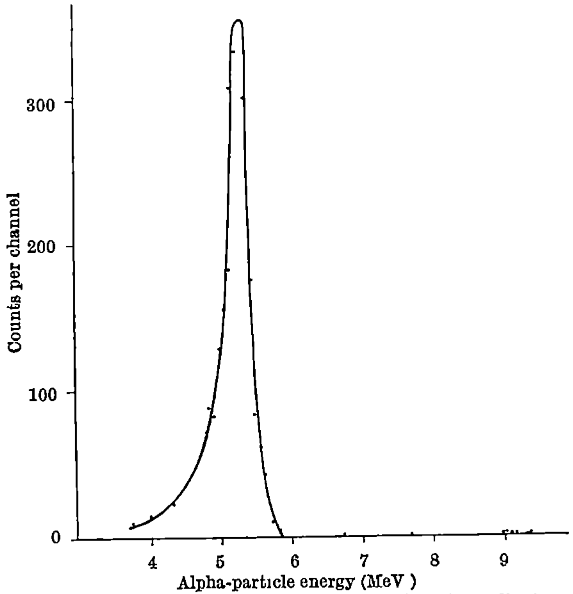

Fig 2 Grass ash Total specific alpha-activity 6 4 × 10^{-12} c /gm Counting time 36 hr

from the spectrum to be in equilibrium with radium-226 Uranium-238 and thorium-232 are absent and the thorium-228 must therefore be presumed to originate from radium-228 (MsTh 1) rather than by metabolic uptake of the element thorium A similar spectrum, but showing relatively higher radium-226, has been obtained for Brazil nuts, which are known to have very high alpha-activity[3], these results have been published elsewhere[4].

Measurements have been made in these laboratories of the total alpha-activities of grass samples taken from various localities[13], and values found in Great Britain have ranged from 1 0 to 170 × 10^{-12} c per gm of ash Spectra of the form shown in Fig 2 have been obtained from all the grass samples that we have analysed so far, which have been collected from several different parts of the country It will be seen that this spectrum is of different form from that of Fig 1, most of the activity being concentrated in a small energy-range While it is not possible from our spectral evidence alone to decide with confidence whether the nuclide concerned is polonium-210 (5 30 MeV) or plutonium-239 (5 14 MeV), evidence from chemical analysis and from the build-up of activity with time, after ashing at 500° C , has established that the nuclide is, in fact, polonium-210 in the presence of lead-210 (RaD) From this spectrum we conclude that polonium-210 accounts for some 90 per cent of the total alpha-activity of the grass ash

In view of the known tendency for the kidney of several species to take up polonium[14,15], we have examined the kidney of a sheep that had been grazed in the district from which the grass sample

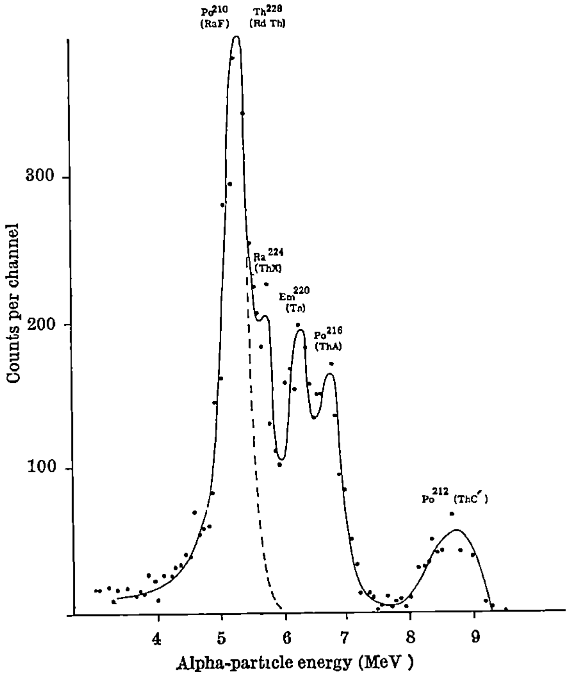

Fig 3 Sheep's kidney Total specific alpha-activity 6 0 × 10^{-12} c /gm ash Counting time 48 hr

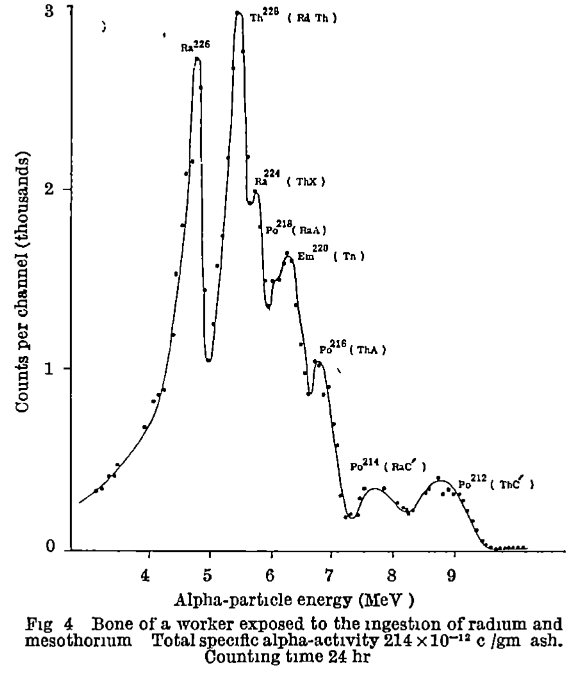

Fig 4 Bone of a worker exposed to the ingestion of radium and mesothorium Total specific alpha-activity 214 × 10^{-12} c /gm ash. Counting time 24 hr

of Fig. 2 was obtained. The total specific alpha-activity was $6 \cdot 0 \times 10^{-12}$ c. per gm. of ash (ash content of wet kidney 1·1 per cent) and the spectrum (Fig. 3) shows that about half the total is due to thorium-228 and its daughters, an observation confirmed by an independent method of estimating thorium series nuclides[2]. In addition, there is a single line of the same energy as that appearing in the grass, presumably again polonium-210. The presence in the kidney of thorium-228 is interesting in view of the absence of thorium-232 and radium-226, although the latter is clearly present in a spectrum taken of the bone of the same animal. The explanation would appear to be that radium, but not thorium, is absorbed by the sheep from its environment and that thorium-228 originates within the sheep by decay of radium-228, being afterwards transported and fixed in the kidney.

The spectroscopy of normal human bone is beyond the capacity of our present equipment, but interesting results may easily be obtained for the bone of those having radium burdens of the order of one-tenth of the maximum permissible level. Fig. 4 shows the spectrum of the bone of a worker who had been exposed to the ingestion of both radium-226 and radium-228 and whose body burden of the former isotope was estimated[2] at $5 \cdot 9 \times 10^{-8}$ c. The presence of radium-226 and of radium-228 with its daughters is clearly demonstrated.

Potentialities of the Method

It seems clear that this type of alpha-ray analysis will prove of great value in the study of the radioactivity of biological materials. We are therefore constructing equipment that should be capable of analysing, with improved resolution, the ash of most living tissues.

We are greatly indebted to our colleague, Dr. R. C. Turner, with whom we have had many fruitful discussions concerning the interpretation of these spectra. Our thanks are due to Mr. J. O. Crookall for the chemical evidence concerning polonium and to Mr. S. P. Newbery for invaluable help with the electronic equipment. We are also indebted to Dr. U. Facchini and his colleagues of C.I.S.E., Milan, who kindly analysed a number of samples for us in their gridded parallel plate chamber before our own instrument was completed.

THE OHIO STATE UNIVERSITY 360-FT. RADIO TELESCOPE

By Prof. JOHN D. KRAUS
Ohio State University

For some years mapping of the radio sky has been a principal activity at the Ohio State University Radio Observatory. Since it was anticipated that this would also be the case if a larger telescope became available, consideration was given some years ago to a telescope design especially suited for mapping work which would provide the largest possible aperture per unit cost consistent with large sky coverage. The design evolved consists of a fixed standing parabola with a flat reflector which can be tilted to deflect the celestial radiation into it. The general arrangement is shown in Fig. 1. Since the parabola is fixed and supported directly from the ground, a minimum of structure is required. The only moving part is the flat reflector, which is pivoted at ground-level and is required to move through only one-half of the range of declination covered. Although primarily a meridian transit instrument, east–west movement of the feed antenna can provide a small measure of tracking in hour angle. This is not essential, however, in most mapping work.

Scale Model

Experimental work on the design began in 1953 when Robert T. Nash constructed a scale model of the telescope, as part of his thesis work toward a master's degree at the Ohio State University. The parabola of the scale model measured 12 ft. in horizontal length while the wave-length of operation was 1·25 cm. By scaling both the physical size and the wave-length in this manner, antenna patterns can be measured that will duplicate those of the full-size system[1]. Specifically, the system duplicated is a telescope with a parabola 2,000 ft. by 200 ft. operating at 2 metres wave-length or a telescope with a parabola 700 ft. by 70 ft. operating at a wave-length of 70 cm. A photograph of the model is shown in Fig. 2.

Antenna patterns measured by Nash agreed closely with calculated values[2,3]. In fact, the performance of the model was so satisfactory that Nash used it as an actual radio telescope for many observations of the Sun and Moon at a wave-length of 1·25 cm. [4].

Construction of the Full-Size Unit

In 1954 a request was made to the United States National Science Foundation for funds to construct a standing parabola radio telescope with a flat reflector of adjustable tilt, the parabola to be 720 ft. long by 70 ft. high. The minimum wave-

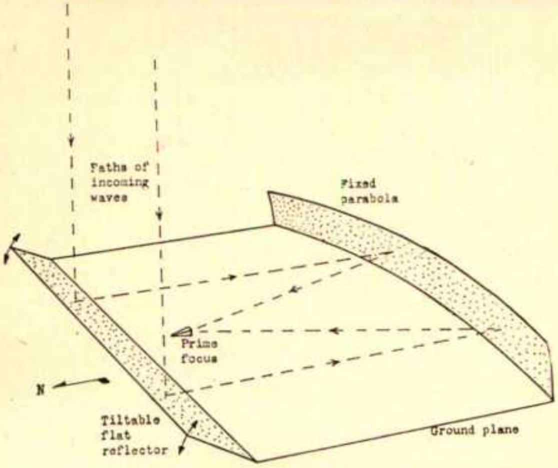

Fig. 1. Principle of operation of the standing parabola radio telescope with flat-sheet reflector. The declination angle of reception is changed by tilting the flat reflector while scanning in right ascension is accomplished by the Earth's rotation

length of operation was to be about 70 cm. and the dimensions were deemed sufficient to provide a significant full-scale test of the design. In 1956 a grant was received from the National Science Foundation for half the amount requested for a parabola 720 ft. by 70 ft. As a result, the plans were modified to build the central half of the telescope so that the parabola would be 360 ft. long by 70 ft. high and the flat reflector of adjustable tilt also 360 ft. long with the possibility that outer sections might be added at some future date. At the suggestion of the Radio Astronomy Panel of the National Science Foundation, the original plans were also modified to make the telescope operate at the hydrogen line (21 cm. wave-length). To maintain surface tolerances at this wave-length required a structure with several times as much steel as in the original design, with a corresponding increase in cost. Two subsequent grants by the National Science Foundation in 1957 and 1958 have brought the total funds provided for the construction of the telescope close to 250,000 dollars.

A sketch of the final design of the telescope is shown in Fig. 3. This sketch is substantially correct, the main discrepancy being that the actual system for elevating the flat reflector uses a winch arrangement instead of a hydraulic cylinder as suggested in the sketch.

The Ohio Wesleyan University provided a 20-acre site for the radio telescope situated about 4 miles from Delaware, Ohio, and near the Perkins (optical) Observatory. The new radio observatory location is known as the Ohio State–Ohio Wesleyan Radio Observatory.

Construction on the telescope began in 1956 with work on the parabolic reflector. The mechanical design of the structure has been the responsibility of Robert T. Nash and the construction also has been carried out under his supervision. The construction crew has consisted of about ten men, most of whom have been Ohio State University students who have worked on the telescope on a part-time basis. The parabola was completed in 1958 and work started on the flat reflector. A view of the completed parabola is shown in Fig. 4. At the time of writing (July) the foundations for the flat reflector are mostly in place and sub-assemblies of the steel structure nearly completed. One section of the flat reflector has been assembled and preliminary tests of the hoisting and locking system carried out.

Specifications

The parabola (360 ft. × 70 ft.) is a section of a paraboloid of revolution with axis coincident with the ground plane and passing through the prime focus. The focal distance is 420 ft. The aperture area is 25,200 sq. ft. or about 0·6 acre. This area is equal to that of a circular aperture parabolic dish antenna nearly 180 ft. in diameter. The reflecting surface of the parabola consists of vertical copper-clad steel wires 0·081 in. in diameter spaced 1 in. between centres. The entire wire-supporting structure of the parabola is hung from the main parabola framework by adjustable brackets in order to facilitate adjustments of the parabola surface if required. The ultimate surface deviation of the parabola is expected to be less than ½ in.

The flat reflector is constructed in movable units 20 ft. wide (east–west) by 100 ft. long in the slant direction. Under normal loading conditions the maximum deflexion of this structure from a flat surface is expected to be of the order of ¼ in. Such movable units are to be mounted with a 40-ft. spacing between centres. Each unit is to be equipped with an individual 3 h.p. electric winch and fast-acting pneumatically operated brake and lock. The winch elevates or lowers the flat reflector unit so that the declination may be changed at a rate of about 5° per min. Twenty-foot beams hinged on each end

Fig. 3. Sketch of the standing parabola radio telescope with flat-sheet reflector being built at the Ohio State University. The central section of the telescope, shown in heavy lines, is the part now under construction, with the end sections, in phantom view, showing possible future additions

will bridge the space between movable units. The actual reflecting surface will consist of the same type of wire with the same spacing as used in the parabola. Although each movable unit of the flat reflector is itself rigid, the flat reflector as a whole is non-rigid since the hinged connecting beams permit each unit to be moved a couple of degrees independently of the adjacent units. The surface of the flat reflector will be monitored with an optical telescope placed at a point on the axis of rotation (along the base of the flat reflector) west of the reflector, and units adjusted individually until the desired declination of all units is attained.

The steel in the parabola and flat reflector has a total weight of about 300 tons while the concrete in all the foundations totals about 1,200 tons. The horizontal ground plane between the parabola and the flat reflector will consist of thin aluminium sheet a few thousandths of an inch in thickness, on flat 'Polyfoam' slabs floated on the surface of a water-filled pond. It is anticipated that the surface of this ground plane can be maintained flat to less than $\frac{1}{2}$ in.

The antenna feed system at the prime focus will be situated on a peninsula covered with conducting sheet which extends south from the base of the flat reflector into the pond. At the higher frequencies horn antennas will be used as was done with the scale model (see Fig. 2), while corner reflectors will be used at lower frequencies. It is planned to operate the telescope at wave-lengths from 15 cm. to 15 metres, a range of 100 to 1. The polarization is vertical. The presence of the horizontal ground plane, which acts as an electrical image plane, reduces the required height of the feed antenna to one-fourth of the value which would be needed if no ground plane were present. Owing to the large horizontal dimension of the standing parabola, the required horizontal dimension of the feed antenna is also small. As a result, the aperture blocking or area of obstruction presented by a single feed antenna is very small, amounting in a typical case to only about one-tenth of one per cent of the aperture of the parabola. Accordingly, a multiple feed can be employed without objectionable blocking of the aperture to provide simultaneous operation over a wide range of wave-lengths. It may even be possible by means of a multiple feed to construct a rudimentary radio camera having as many picture elements as primary feed antennas.

The fact that the feed point is at ground-level completely eliminates the problem of supporting the feed antenna and maintaining its alignment, a problem present in all steerable telescopes. Furthermore, there is almost no limitation to the weight and complexity of the equipment placed at the feed point, so that feed cable losses are eliminated and low-noise amplifiers of the maser and parametric type can be used to best advantage.

At the highest frequency of operation (15 cm. wave-length) the half-power beam-widths of the telescope antenna will be 0·1° in right ascension by 0·5° in declination. (Initially the beam-width in right ascension at 15 cm. will be twice this value, since only the central 180 ft. of the parabola has a reflecting wire spacing of 1 in. and only this portion will be useful at 15 cm. The outer portions have a wire spacing of 3 in. and at longer wave-lengths the entire parabola can be used. However, initially only the central 260 ft. of the flat reflector will be completed. These modifications, which were necessitated by a lack of funds, will somewhat hamper initial

Fig. 4. View of the completed 360-ft. parabola from the west

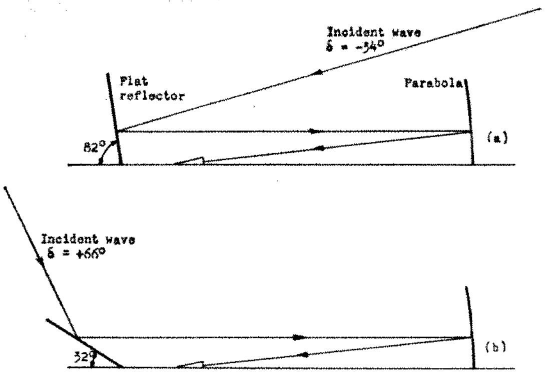

Fig. 5. Diagrams showing extreme positions of the flat reflector and corresponding wave or ray paths

operation of the telescope, but it is hoped that these deficiencies can be remedied at an early date.) This fan beam from the antenna has the same area resolution as a symmetrical pencil beam with a half-power beam-width of about 0·2°. However, the fan beam has the advantage over the pencil beam of reducing the time required for a complete scan of the sky by a factor of about 2·5, and also of providing twice the resolution in the direction in which the sky is scanned. A fan beam is also valuable for the reason that it differs in shape from the pencil beam typical of most steerable dish antennas. Thus, comparisons of source and background surveys made with beams of different shape are valuable in detecting spurious effects, since beams of different shape are, in general, subject to different aberrations.

Although no tracking ability is required for most sky-mapping work, a small measure of tracking can be provided in the new telescope by some east–west movement of the feed antenna. Tests of the displacement of the feed antenna on the scale model showed that tracking of sources in hour angle may be possible for at least 10 min. in time at the highest frequency of operation and for more than 1 hr. at lower frequencies. With vertically polarized feed antennae the electric field vector is perpendicular to the horizontal ground plane, so that the intensity along the ground plane can be a maximum. Under these conditions the telescope is most efficient and operation is restricted to vertical polarization by providing only vertical wires in the reflecting surfaces of the standing parabola and flat reflector.

The flat reflector is designed to tilt to angles between 32° and 82°, as illustrated in Fig. 5. A motion of the flat reflector through 50° (from 32° to 82°) results in a motion of the antenna beam through twice this value, or from a declination of 66° N. to 34° S. (total 100°). The latitude of the telescope site is about 40° N. Since the galactic equator is at about 29° south declination, the telescope will be useful for studies of the region of the galactic nucleus. The fact that the most northerly observable declination is 66° (24° from the celestial pole) reduces the sky area coverage only by a small amount, the unobservable area being only about 6 per cent of the observable sky. Since the slant height of the flat reflector is 100 ft., while the parabola is 70 ft. high, the full aperture of the parabola can be utilized at all declinations south of 40° N. At the most northern declination of operation (66°), the vertical height of the flat reflector will be 76 per cent of the height of the parabola, reducing the useful aperture of the telescope by 24 per cent under these conditions.

The primary or feed antenna radiation will be tapered in order to reduce the minor lobes of the telescope beam pattern to a minimum. This is important in eliminating spurious responses or ghost sources. An important characteristic of the design is that signal pick-up from the ground is minimized, the telescope antenna beam pattern being always directed skyward with the parabolic and flat reflectors providing a measure of shielding from interfering terrestrial signal sources.

The fact that the main part of the telescope has only one moving part, the flat reflector, the position of which can be accurately controlled, means that it will be possible to measure positions of celestial sources to a high precision and with good repeatability.

Conclusion

The new Ohio State University telescope will be an experimental working model of the standing parabola tiltable flat reflector design which should provide useful information for the construction of similar telescopes of even larger size. It is hoped that the telescope will be completed during 1960, at which time a programme of sky-mapping will be initiated that will cover a wide range of frequencies. More detailed sky maps and more accurate spectra of radio sources will be objectives of the surveys. Instrumentation for hydrogen line observations is also to be installed, and observations conducted of the distribution of neutral hydrogen in our galaxy.

RADIOCARBON DATING

CONTRIBUTIONS were made by representatives of each of the three laboratories in England which are actively engaged in radioactive dating to a joint session of Sections A (Physics) and H (Anthropology and Archæology) of the British Association at the recent meeting at York. They combined to provide a picture of the basis of the method and its limitations, the trend of future development in instrumentation, and the capabilities of the method as applied to individual problems in the late Quaternary history of the British Isles.

In reviewing the basis of the method of radiocarbon dating, Mr. H. Barker, of the British Museum Research Laboratory, was concerned with the difficulties which had sometimes arisen as a result of the lack of common ground between the archæologist and the physicist. Lack of familiarity with statistical concepts and misunderstandings as to the nature of radioactive decay had led to many misconceptions and the validity of the method had been questioned on wrong premises. The method depends on the fact, predicted and verified by Libby, that the radioactive carbon isotope of mass 14 (known as radiocarbon or carbon-14) is being continually created in the upper atmosphere as a result of the action of cosmic rays Consequently it is distributed throughout the world-wide carbon-exchange reservoir which comprises the atmosphere, the oceans, and all plant and animal life Libby produced sound theoretical argument, backed by practical measurements, for assuming that the carbon-14 is evenly distributed throughout the exchange reservoir and that the level of radioactivity due to this cause has remained the same for many thousands of years This assumption is fundamental to radiocarbon dating, when an organism dies it is cut off from the exchange reservoir, the possibility of it replenishing its carbon-14 by vital processes ceases, and its store of carbon-14 diminishes at a rate determined only by the half-life (about 5,600 years) One can therefore calculate the time which has elapsed since it was alive, from a measurement of its residual carbon-14 activity, provided that one can assume that its original activity was the same as that of a reference sample which has been recently removed from the reservoir The measurement is exceedingly difficult, and limitations in accuracy, imposed by statistical fluctuations in the measurement of radioactivity, result in an error term being associated with each radiocarbon date The correct interpretation of the significance of this error-term requires some familiarity with statistical concepts, and lack of appreciation of this has led to misunderstandings

In the ten years which have elapsed since Libby announced his first successes, there has been a revolution in instrumentation Nowadays, the measurement of radioactivity can be made to a much higher accuracy, and the question arises as to whether the basic assumption of the method still holds good at this new level of accuracy In fact, it seems that a number of minor effects can combine to limit the accuracy Craig showed that isotopic fractionation in plants can result in fluctuations of up to ± 1 per cent in carbon-14 activity from the mean value This corresponds to an error of ± 80 years Fortunately, it is possible to apply corrections for this effect based on mass-spectrometric measurements of the ratios of the other carbon isotopes in the sample and the standard Systematic errors, mainly due to differences in 'recent' standards, have caused difficulties in comparing results between different laboratories In most cases, the errors are quite small, but steps are now being taken to eliminate these differences Very recently, de Vries has shown that the level of activity in the exchange reservoir has suffered cyclic changes of about ± 1 per cent during the past 500 years So far as one can see at present, this effect definitely limits the accuracy obtainable in dating to about 100 years

Apart from these theoretical limitations, it must not be forgotten that the choice of sample plays an important part in the real accuracy obtainable The archæologist has to relate the death of an organism (which is what is actually measured) to an event in which he is interested The environment of the sample is not unimportant, the possibility of sample contamination must not be overlooked, and suitable laboratory treatment applied when necessary to remove contaminating materials such as rootlets and humic acids

Mr W J Callow, of the National Physical Laboratory, also referred to the factors which limit the accuracy of the method, but pointed out that, despite these limitations, the radiocarbon method remains a very valuable technique for chronological studies in archæology, geology, botany, oceanography and allied fields There are now nearly forty laboratories distributed throughout the world which have been, or are, currently engaged in this form of dating Some time ago, it was realized that there was a need for a dating service to be made generally available to workers in Great Britain The laboratories at the Botany School, Cambridge, and the British Museum were occupied in the main with their own programmes, and it was considered appropriate that the new service should be set up at the National Physical Laboratory

The instrumental difficulties are considerable in that the measurement is concerned with levels of radiocarbon concentration ranging from one part in a million million down to zero In the case of recent carbon, this corresponds to the breakdown of about fifteen carbon-14 atoms per min per gm of carbon Detecting and recording these disintegrations requires special techniques due to the low energy of the beta-particles and the low counting-rates involved

In all methods, the first process involved consists of converting the sample to carbon dioxide, either by combustion, in the case of organic material, or by acid treatment, in the case of carbonates In Libby's original method the carbon dioxide was reduced to solid carbon which had to be placed inside a counter because of the low beta-particle energy Due to the low efficiency of the counter under these conditions and the possibility of contamination with radioactive fall-out and naturally occurring radon, this technique has now been abandoned

Both de Vries in Holland and Fergusson in New Zealand have shown that carbon dioxide itself, if sufficiently pure, can be used as the operating gas in a proportional counter, and this technique is being adopted at the National Physical Laboratory As little as one part per million of electronegative impurity such as oxygen or oxides of nitrogen in the carbon dioxide can prejudice the reliable operation of the counter, and hence the accuracy of the measurement The gas preparation equipment at the National Physical Laboratory is therefore designed to produce carbon dioxide of an extremely high degree of purity.

Carbon dioxide is not the only possible counter filling, methane and acetylene are in use in some laboratories Both involve rather more preparatory work, but they are more tolerant of the presence of impurities Acetylene has the advantage of having two atoms of carbon in its molecule, and therefore, under a given set of conditions, the use of it enables one to place twice as much carbon in the counter compared with carbon dioxide or methane methods

Liquid-scintillation counting also provides a possible approach to the problem of measurement, but difficulties in chemical preparation prevent its general adoption

The actual measurements are complicated by the fact that, in normal circumstances, the background counting-rate of the counter would be very much greater than that due to the sample itself, and steps must be taken to reduce its value A heavy steel screen with walls 8 in thick is used to eliminate the effect of local gamma-radiation The screen at the National Physical Laboratory, which is large enough to accommodate a number of counters, weighs more than 23 tons The penetrating meson component of cosmic radiation, against which the steel screen has no effect, is cancelled out by a ring of Geiger counters surrounding the sample counter and connected in anti-coincidence Other screening precautions which have been shown to be advisable and which are incorporated in the equipment at the Laboratory include a mercury shield, which reduces the background due to traces of radioactivity in the steel screen, and a layer of paraffin wax mixed with boric acid which reduces the component due to neutrons which are in turn induced in the screen by the action of the corpuscular component of cosmic radiation This neutron flux will also be monitored continuously Since accurate measurement of these very low disintegration-rates necessarily takes a long time, great emphasis has been placed on the reliable operation of the associated electronic equipment The instrumentation at the National Physical Laboratory is based on the use, wherever possible, of high-stability circuits as used in computers, and of transistors instead of thermionic valves The equipment includes a comprehensive system for automatic recording, and a mass spectrometer has also been purchased in order that corrections can be applied for isotopic fractionation effects The equipment is nearing completion and should be in operation in the near future

Dr H Godwin described how the method is being used in the Cambridge Sub-department of Quaternary Research to give an absolute time-scale to the history of events during the Late Quaternary period, that is, the past 35,000 years or so The apparatus, designed and built by Dr E H Willis, consists of a proportional gas counter of about 2-litres volume It is shielded by 7 tons of zinc and lead and an anti-coincidence array of Geiger tubes It has a net contemporary count-rate of 28 counts per min and a steady background of 20 7 The equipment was acquired as a result of the generosity of the Nuffield Foundation, but is now maintained by the University of Cambridge

The oldest sample dated so far was from the Arctic Plant Bed from the Lea Valley This gives a date of 26,000 B C for the time when the mammoth was still alive in Britain A date from a later horizon in the valley of the Colne, a tributary of the Lea, shows that the full Glacial Period must have persisted until *c* 11,500 B C After the glaciation, there came a period of climatic oscillation, the so-called Allerød Period The effects of this change can be recognized in deposits at numerous sites throughout the British Isles Carbon dating on material from such sites shows that there was a temporary mild period between 10,000 and 8,800 B C, followed by a return of cold for about 500 years These British dates are in excellent agreement with dates from north-west Europe As a result, British events are now closely tied up with events at the end of the ice age in Europe

Following the Allerød oscillation came the climatic improvement of the Post Glacial Period In the past, pollen analysis has provided a relative time-scale for this period since the characteristic changes in forest composition have permitted the establishment of a sequence of pollen zones applicable, with care, to the whole of the British Isles A series of twelve datings from a site in Cumberland gives a very consistent series of dates for the successive pollen zones It remains to be seen how far these pollen boundaries are truly synchronous across the British Isles or Western Europe

The increased temperature at the end of the last glaciation caused melting of the ice sheets and a rapid rise in ocean-level One effect of this was the flooding of the North Sea and the isolation of Britain from the European mainland Dates measured in Cambridge on submerged peat-beds from around the coast of Britain, together with those made at other laboratories, show that a rapid eustatic rise of sea-level was in progress between 12,000 and 4,000 B C and that the level rose by more than 200 ft

In the derelict raised bogs of Somerset, several prehistoric wooden trackways have been recorded and excavated They appear to have been built in the late Bronze Age at a time when increasing wetness of climate induced flooding of bogs and valleys and caused Bronze Age man to construct these wooden causeways Radiocarbon dating of seven such structures in Somerset and three others in Lancashire, Cambridgeshire and Lincolnshire show that they were built in the period 500–900 B C

The picture which emerged from this discussion is a very hopeful one for the future of radiocarbon dating in Britain Although the method has certain limitations, the work described by Dr Godwin illustrates its great value as a tool for establishing an absolute chronological framework to prehistoric events, and the news that Britain's present limited capacity for radiocarbon dating is to be augmented by the considerable resources of the National Physical Laboratory will be welcomed in many quarters The dates mentioned in the discussion appear in a paper in the *American Journal of Science* Radiocarbon Supplement, Vol 1 (1959), the new international organ for the publication of radiocarbon dates

HAROLD BARKER

MECHANISM OF HORMONE ACTION

By PROF AARON B LERNER

Section of Dermatology, Department of Medicine, Yale University School of Medicine, New Haven, Conn

CELLS have specific functions, for example, adrenal cortical cells produce hydrocortisone, nerve cells form noradrenaline, melanocytes make melanin During their early development cells have in common the capacity to produce substances such as glycogen and protein The formation of all these end-products depends upon the reaction of specific enzymes with their substrates Such enzymically catalysed syntheses usually occur in soluble extracts and homogenates which do not contain intact cells The formation of cellular end-products also is controlled by hormones that require a high degree of cellular organization in order to function Although the synthesis of a cell's products is regulated by both enzymic and hormonal reactions, these reactions are not related directly to one another The hormones

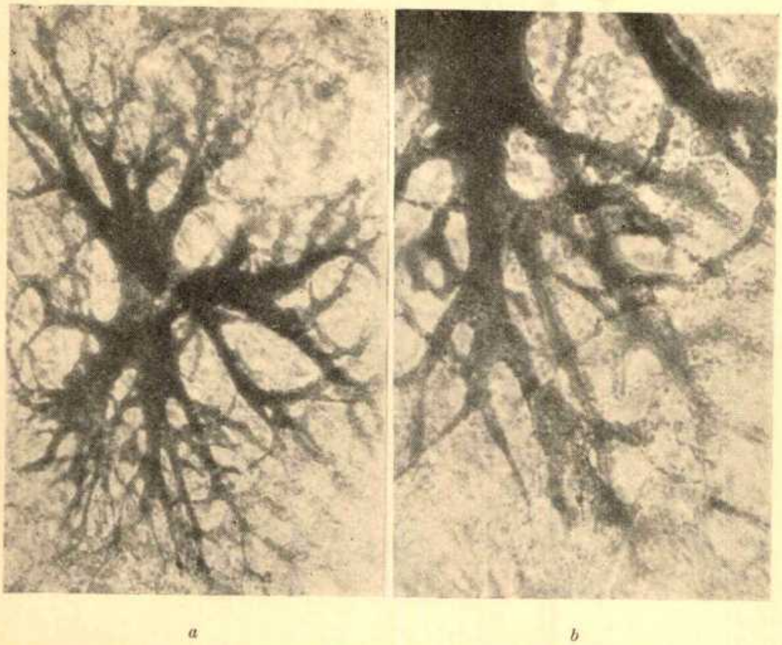

Fig. 1. The pigment granules in a frog's melanocyte can be dispersed throughout the cell as shown above (*a*, × *c*. 320 ; *b*, × *c*. 720) by keeping the cell in solutions of either low osmotic activity, low pH or relatively high potassium and low sodium ion concentration. α- and β- melanocyte-stimulating hormone and adrenocorticotrophic hormone and caffeine also caused dispersion of granules. While these physical and chemical factors produce the same end effect, namely dispersion of granules within the cell, they do so through different mechanisms (see Figs. 3 and 4). At × 720 magnification the melanin granules are seen easily

react with the intact cell to initiate a series of reactions, none of which need be enzymic, that result in a re-location of enzymically active particles. Afterwards, the enzymic reactions concerned with the formation of various cell products also are affected. The nature of the first reaction of the hormone with the cell is still unknown. It may involve a specific interaction between the hormone, cytoplasmic structural proteins, ions and water to change the colloidal state of parts of the cell.

In this article I wish to show that the melanin pigment forming cell, the melanocyte, must be intact if hormones are to affect the rate of melanin synthesis. Initially, hormones do not affect the tyrosinase-catalysed conversion of tyrosine to melanin. Instead they produce a change in the location of enzymically active particles which is followed by a change in the rate of enzymic reactions forming melanin. If hormones were added to tissue extracts without intact cells, no effect on melanin synthesis would be observed. A similar mechanism may apply to the action of hormones on cells other than melanocytes.

What makes the melanocyte a unique cell in which to study the action of hormones is that it contains enzymic particles made dark by melanin. Hence, these particles are readily visible. Of course, it cannot be assumed that a hormone like adrenocorticotrophic hormone acts on the melanocyte in the same way as it does on the fibroblast. Nevertheless, the studies with melanocytes are reasonably clear-cut and must be acknowledged. Perhaps at a later date techniques will be made available to facilitate similar observations on other cells.

Melanocytes resemble nerve cells. Embryologically they are derived from the neural crest. The pigment melanin is made in the cytoplasm of the melanocyte by the reaction of tyrosine with oxygen and tyrosinase. Ordinarily this reaction occurs on cytoplasmic particles that contain not only tyrosinase activity but that of other enzymes as well. For example, the tyrosinase particles from mouse melanoma also possess cytochrome oxidase and succinic dehydrogenase activities. The melanin formed is normally attached to these particles—thus the particles are visible. These particles are called melanin granules or pigment granules and are considered to be mitochondrial structures[1].

It is easy to show that some physical and chemical factors induce clumping of melanin granules about the centre of the cell while others cause dispersion of these granules in the cytoplasm away from the centre

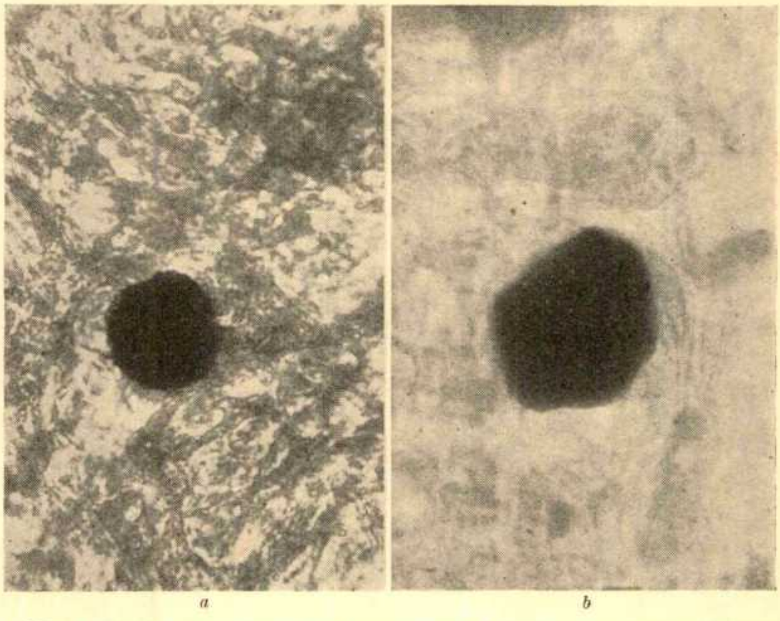

Fig. 2. The pigment cell above is the same kind as that in Fig. 1 except that the cytoplasmic granules are aggregated about the nucleus instead of dispersed throughout the cell (*a*, × *c*. 320 ; *b*, × *c*. 720). The outer borders of the cell, although not shown in this preparation, are the same as in Fig. 1. Aggregation of granules can be induced by placing the cell in solutions of either high osmotic activity, high pH or relatively low potassium and high sodium ion concentration. Melatonin, adrenaline, noradrenaline, acetylcholine, hydrocortisone, serotonin and triiodothyronine also produce aggregation of granules. As in the case of dispersion of pigment granules, aggregation is caused by many factors, all of which produce the same end result but operate through different means (see Figs. 3 and 4)

of the cell. When frog melanocytes are placed in solutions of low osmotic activity or low pH, the granules disperse[2]. A similar effect is achieved by changing the cations in the solution from sodium to potassium. A substance like adenosine triphosphate, which may not even enter the cell, also causes dispersion of the granules. Experiments with frog and fish melanocytes indicate that for the dispersion effect to occur the cytoplasm changes from a gel to a sol and oxygen is utilized. One of the most surprising findings associated with this reversible dispersion reaction is that minute quantities of certain hormones can bring it about. The melanocyte-stimulating hormones from hog pituitary gland, α- and β-hormones, produce darkening in concentrations of 1×10^{-11} M and 2×10^{-11} M, respectively[3,4]. Hog adrenocorticotrophic hormone is effective at 3×10^{-10} M. These three peptides have related amino-acid sequences in their structure[5]. Other dispersing agents include progesterone, caffeine, marsilid and mesantoin. However, when compared with α- and β-melanocyte-stimutating hormones and adrenocorticotrophic hormone, huge quantities are required. Melanocyte-stimulating hormone in high concentrations has no effect on the tyrosine-tyrosinase reaction *in vitro*.

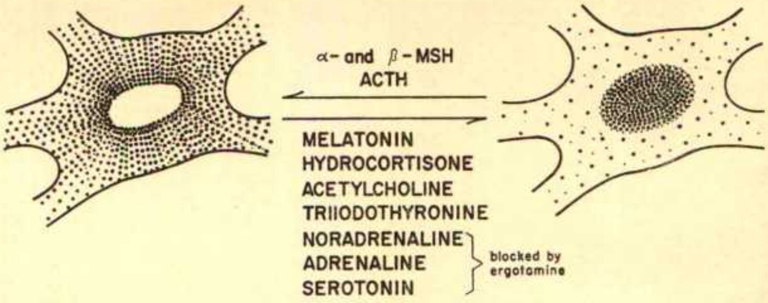

Fig. 3. α- and β-melanocyte-stimulating hormone and adrenocorticotrophic hormone can produce dispersion of pigment granules in the melanocyte. This action can be reversed by the seven compounds listed above. The action of adrenaline, noradrenaline and serotonin but not that of the other aggregating agents can be blocked by ergotamine

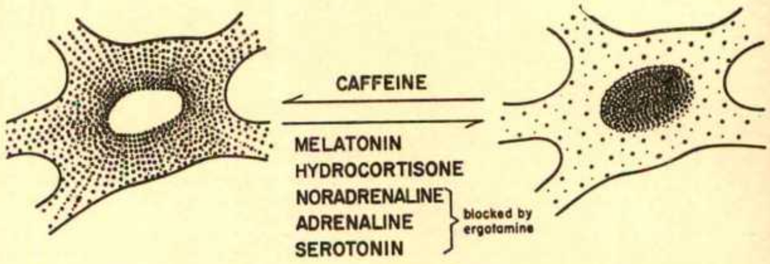

Fig. 4. Caffeine, like α- and β-melanocyte-stimulating hormones and adrenocorticotrophic hormone, causes dispersion of granules in the melanocytes. However, this effect is reversed by melatonin, adrenaline, noradrenaline and serotonin but not by triiodothyronine, acetylcholine or hydrocortisone. The action of adrenaline, noradrenaline and serotonin but not that of melatonin and hydrocortisone can be reversed by ergotamine. Melatonin and hydrocortisone are the only substances known that not only cause aggregation of granules in cells previously darkened by α- and β-melanocyte-stimulating hormone, adrenocorticotrophic hormone or caffeine but also cannot be blocked by ergotamine. However, the action of melatonin and hydrocortisone is not the same. Hydrocortisone acts for only a period of several minutes whereas melatonin has a prolonged action

Aggregation of pigment granules in frog melanocytes occurs in solutions of high osmotic activity or high pH. Replacing potassium by sodium ions in the solution results in a similar effect. Results of work on frog and fish indicate that for the aggregation reaction to occur the cytoplasm must change from a sol to a gel. Oxygen is not required. Potent aggregating agents for frog melanocytes include melatonin, noradrenaline, adrenaline, acetylcholine, hydrocortisone, triiodothyronine and serotonin[6,7]. The molar concentrations of these hormones required for the reaction to occur are 5×10^{-12}, 6×10^{-7}, 6×10^{-7}, 4×10^{-7}, 6×10^{-7}, 8×10^{-7} and 3×10^{-6}, respectively[3].

What happens to the melanocyte when the granules are kept in the dispersed or aggregated state ? In the case of melanocytes from hamster melanoma, injection of melanocyte-stimulating hormone into the animal results in an increase in melanin content of the tumour whereas injection of melatonin results in a decrease in melanin content[8]. Also, injection of melatonin into frogs results in decreased melanin in the skin[9]. Thus in this case, by dispersing tyrosinase, melanocyte-stimulating hormone can bring about more melanin formation. Melatonin, on the other hand, presumably by aggregating the tyrosinase-containing particles, decreases the formation of melanin. In both cases the effect of the hormones on melanin formation is indirect, operating through their influence on tyrosinase location and activity. The activity of the enzyme could well be related to its location within the cell. As suggested earlier, the direct reaction between a hormone and the melanocyte may involve only a relatively specific reaction between hormone, cytoplasmic structural proteins, ions and water to change the colloidal state of parts of the cell[10]. This change in colloidal state eventually would affect the tyrosine-tyrosinase reaction.

The question arises as to whether or not the effect of hormones on the movement of cytoplasmic particles is peculiar to melanocytes or occurs in other cells as well. In this regard it is of interest that adrenocorticotrophic hormone, cortisone and hydrocortisone affect the structure of mast cells[11]. The latter become vacuolated, diminish in size and acquire irregular outlines. Cytoplasmic granules clump together to form aggregates. Cortisone and hydrocortisone induce the formation of cytoplasmic vacuoles in fibroblasts grown in tissue culture. Hydrocortisone also reduces the amount of collagen formed in cultures of fibroblasts.

What I want to emphasize here is that the experiments with melanocytes 'prove' that the intact cell is necessary for the action of a hormone, when action is used in the sense of controlling the end function for which the cell is known, for example, melanin formation in the case of the melanocyte. To change the rate of melanin formation the hormone exerts an indirect effect on the tyrosine-tyrosinase reaction. It is not possible to demonstrate a direct hormonal effect on this reaction. This situation is somewhat analogous to some of the old problems of mathematics. For years attempts had been made to trisect an angle or square a circle with only a pencil, straight edge and compass, or to find a formula to solve equations of the 5th order. However, in fairly recent times it has been shown clearly that these problems cannot be solved in a strict sense. Only approximations are possible. In biology, unlike mathematics, clear-cut proofs are hard to come by. But the experiments carried out by many investigators suggest the conclusion that it is essential for the cell or organized cell unit to be intact in order that a hormone may exert its effect.

THE NUCLEAR-POWERED SHIP, *SAVANNAH*

THE marine world has become accustomed to the reality of nuclear-powered ships through the widely publicized performances of the American submarines *Nautilus* and *Skate* and the building of the Russian icebreaker *Lenin*. These are specialist craft in which the economics, conveniences and safety precautions pertinent to merchant shipping play no part. To test the possibilities of the application of nuclear power to a vessel normally carrying passengers and a mixed cargo the nuclear-powered ship *Savannah*, named after the first steamship to cross the Atlantic, is now being built by the New York Shipbuilding Corporation for the U.S. Atomic Energy Commission and the U.S. Department of Commerce. She is specifically designed as a test ship, to obtain information on practical construction and operating technology, though it is realized that at the present stage the ship is not an economic proposition.

The *Savannah* is of 22,000 tons displacement when loaded, nearly 600 ft. in overall length, and draws 29.5 ft.; she has a cargo capacity of 10,000 tons, carries 60 passengers, a crew of 110, can cruise at 21 knots, and is expected to be ready for unrestricted operation by summer 1960. Externally, the design appears advanced and pleasingly simple. She has sweeping lines with a well-raked stem and cruiser stern. The superstructure incorporating the bridge and sheltered decks is placed well aft, with four holds forward of the bridge. Passenger accommodation is conventionally luxurious, while cargo-handling equipment is of the most advanced and fastest type.

The propulsion plant normally develops 20,000 s.h.p. absorbed by a single screw. The pressurized water reactor, the type used in the *Nautilus*, is fuelled by uranium oxide with about 4.4 per cent enrichment of uranium-235, clad in stainless steel rods, and cooled by light water at a pressure of 1,750 lb./sq. in., heat being abstracted from the core by a three-pass flow arrangement. Emphasis has been placed on the necessity for a long lifetime of the core, the design target being 52,000 MW. days or 3½ yr. under normal operating conditions; a large low-density core is therefore used, while the use of uranium-235 as a fertile material is expected to extend the life of the core through its conversion to plutonium. The variation of power output demanded from the bridge can be met by automatic operation of the boron – stainless steel control-rods.

At normal load the inlet temperature of the primary coolant, demineralized water flowing through two closed loops, is 494.7° F. and the outlet temperature 521.3° F., the coolant being circulated by four pumps and the heat supplied by the reactor rejected to the secondary circuit steam generators. The primary water is continually purified to remove corrosion, fuel and fission products.

The heat rejected by the primary coolant is used to generate steam in the secondary circuit from two generators which supply dry saturated steam at 490 lb./sq. in. to high- and low-pressure De Laval turbines driving the main shaft through a double reduction gear. Two 1,500-kW. steam-turbine generators provide power for auxiliary services and a low-pressure heat exchanger provides steam for hotel services and space heating. For emergency two 750-kW. diesel-driven generators provide power for removal of reactor heat after shut-down and will supply essential services, including the take-home motor coupled to the main shaft.

The installation of nuclear power plants in merchant shipping presents grave problems of ensuring the complete safety not only of both passengers and crew, but also of the inhabitants of the ports of call. It is not sufficient to guard against the hazard of a major explosion. Complete precautions must also be taken against the possibility of irradiation caused by collision or by the sinking of the ship in shallow water. Safety considerations have been elaborate on the *Savannah*. The design of the hull is such that the ship will remain afloat with two of the eleven main compartments flooded: this is not an abnormal requirement, but in the *Savannah* elaborate collision bulkheads and collision mats ensure that a ramming ship would have to penetrate 17 ft. of stiffened ship structure before the containing vessel of the reactor was affected. The inner bottom below the reactor is also strengthened by transverse and longitudinal members to form an 'egg crate' construction. It is estimated that the reactor compartment is impervious to any collision with all but 1 per cent of the world's mercantile marine; the likelihood of high-speed collision in harbour waters is considered negligible.

The chief radiation sources are the reactor core and the primary coolant. The reactor is shielded by a lead-covered steel tank which surrounds the reactor with an annular water space. It is estimated that the dose-rate outside the primary shielding will not exceed 200 mr. per hr. 30 min. after shut down. This rate is low enough to permit approach for inspection and maintenance. The whole of the primary system is further surrounded by a containing vessel, designed to limit the radiation in the holds to 5 r. a year and to 0.5 r. a year in the passenger spaces. The containing vessel, cylindrical in shape, 35 ft. in diameter by 50.5 ft. long, also serves to prevent spread of radioactivity in the event of any rupture of the primary system The lower half of this vessel is of concrete surrounded by water tanks, while the upper half is of lead slabs surrounded by polyethylene Should the ship sink in deep water, two of the manholes will open automatically to equalize pressure and then close to prevent undue leakage of radiation products Provision is also made in the case of shallow-water sinking to allow purging of the containing vessel or filling it with concrete The total weight of the containing vessel is about 2,000 tons

Waste liquids likely to be radioactive are fed to storage tanks and will not be discharged at sea except under the conditions set forth by the Maritime Administration and the Atomic Energy Commission Radioactive gases are diluted and discharged up the radio mast after being filtered Purging of the air of the containing vessel, of which the argon is slightly radioactive, is carried out periodically at sea Cooling of such components as primary circulating pumps is effected by fresh water cooled by sea water in an intermediate circuit The sea water does not become radioactive

Apart from the care taken in the design and construction of the ship, extensive training in nuclear reactor theory and its marine application is being undertaken by the candidates for the posts in the *Savannah* The longest course taken by engineering-officer candidates occupies fifteen months A shorter course has also been arranged and is intended for candidates already possessing a science degree and includes seven observers from Britain, Denmark, Holland and Japan

F D ROBINSON

OBITUARY

Sir Alfred Egerton, F R S

ALFRED CHARLES GLYN EGERTON died suddenly on September 7 following a heart attack He was on holiday at the time at his house at Mouans Sartoux in the south of France, with his wife and son Francis He was seventy-two, but was in full vigour, his sudden death comes as a great blow to all those in combustion science, in which Sir Alfred has been the acknowledged leader for many years He had also made many important contributions in engineering, and in scientific administration and education

He was educated at Eton, where he took the science prize and founded the College Scientific Society, and at University College, London, where he gained first-class honours in chemistry and was later president of the College Chemical and Physical Society He studied at Nancy and in Berlin with Prof W Nernst, and in Sir William Ramsay's private laboratory as his last research student During 1909–13, he was instructor at the Royal Military College and, during the First World War, carried out research on explosives and had his first contact with chemical engineering

After the War Egerton went to the Clarendon Laboratory at Oxford and carried out researches on the vapour pressures of metals at high temperatures and, in advance of his time, worked on the separation of zinc isotopes He was appointed reader in thermodynamics in 1923 During a British Association meeting in Canada, Sir Harry Ricardo and Sir Henry Tizard, with whom his friendship was life-long, aroused his interest in combustion and in the role of the newly discovered 'anti-knocks' He applied his knowledge of physical chemistry to this problem of knock in internal combustion engines and put forward the view that break-down of unstable organic peroxides was responsible for 'pre-sensitizing' the premature detonation His interest in combustion continued throughout his life, and he and his research group published a steady stream of valuable papers on the role of peroxides in combustion, on peroxide analysis, on slow combustion processes, on gaseous detonation, on limits of inflammability, on burning velocities, and on techniques for these studies, such as the use of absorption spectra and the development of the flat-flame burner

Egerton also carried out or stimulated work in many fields of applied science He made measurements of the properties of that important working substance steam, and stressed the value of methane or natural gas as potentially the most efficient fuel for the internal combustion engine, and worked on the combustion, liquefaction and bulk handling of methane This led to an interest in liquefaction problems, and he was active in founding the Low Temperature Group of the Physical Society, of which he was first chairman in 1946

He was elected to the Royal Society in 1926, and in 1936 was appointed professor of chemical technology in the Imperial College of Science and Technology (University of London), a position which he held until his retirement in 1952 During his tenure of the chair, he started the undergraduate course in chemical engineering and pioneered the development of this subject in Great Britain The Department, under his guidance, became a leading centre in both combustion research and chemical engineering

Egerton was secretary (physical sciences) of the Royal Society during 1938–48, during the important War period, and he was also a member of the Scientific Advisory Committee of the War Cabinet during 1940–45 In 1942, he spent some time in Washington in charge of the British Commonwealth Scientific Office, where he did important work improving Anglo-American co-operation His membership of numerous committees gave him a tremendous breadth of knowledge of affairs and of people At various times he was chairman of the following committees the Heating and Ventilating Committee, the Fuels and Propulsion Committee, Admiralty Scientific Research Department, the Scientific Advisory Council, Ministry of Fuel and Power, the committees reporting to the Government of India on the Indian Institute of Science, and on the sixteen Government of India laboratories, the Scientific Advisory Committee of the British Council, the Combustion and Fuels Committee of the Aeronautical Research Council, and the Royal Society Scientific Information Conference He had been director of the Salters' Institute of Industrial Chemistry and a manager of the Royal Institution He was president of the British Section of the Combustion

Institute, editor of *Combustion and Flame*, and formerly of *Fuel* He was active in work on the dissemination of scientific information (*Science Abstracts* Committee), on the use of scientific man-power (Barlow Committee) and on the use of the world's fuel and energy resources His educational interests are shown by his active membership of the governing bodies of Winchester College and of Charterhouse Last year, he was responsible for the successful organization of the seventh International Combustion Symposium in Oxford His recent intense activity had been on the Government Committee of Inquiry into the Fishing Industry, and in research into the characteristics of smouldering for the Tobacco Manufacturers' Standing Committee His work was recognized by a knighthood in 1943 and a number of honorary degrees and medals, including the Rumford Medal of the Royal Society in 1946

In 1912, he married the Hon Ruth Cripps, only daughter of the first Baron Parmoor, sister of his close friend at University College, the late Sir Stafford Cripps

As a man, we remember his quiet unassuming manner, his unfailing smile of greeting, his tireless work on his many scientific interests, and his delight in his second career as a painter Somehow, despite his many activities, he always had time to spare for everyone He had the genius for bringing out the best in those with whom he worked and took a fatherly interest in the numerous research students he sponsored, so many of them now in high positions in science and industry This keen personal interest in his students, colleagues, and indeed in all he did, was fully shared by Lady Egerton His life and work are an example to all those whom he has influenced

NEWS and VIEWS

Biochemistry at Birmingham Dr S V Perry

The development of a Department of Biochemistry in the University of Birmingham, arising as it does in part from the former Department of Industrial Fermentation, needs for guidance a man of scientific ability and vigorous powers of leadership The appointment of Dr S V Perry to be professor of biochemistry has recently been announced Dr Perry graduated with first-class honours in biochemistry in the University of Liverpool in 1939 and was elected to the Isaac Roberts research scholarship upon graduation After the Second World War he was elected a Rouse Ball research student of Trinity College, Cambridge, and began his researches on muscle biochemistry in the Department of Biochemistry He was elected a research fellow of Trinity College, Cambridge, in 1947 and a Commonwealth Fund Travelling Fellow in 1948, spending the year 1948–49 in the Department of Physiology of the Medical School of the University of Rochester, New York, investigating the biochemical properties of skeletal muscle In 1950 he was appointed a lecturer in biochemistry in the University of Cambridge His researches have been largely concerned with biochemical function in relation to intracellular morphology with particular reference to the muscle cell A study of the intracellular components of striated muscle has been pursued in an investigation of the biochemistry of the cell in general, and of the contractile process in particular These studies are throwing important light on the nature of the association between muscle proteins and the role of their interaction in muscular contraction Dr Perry has taken part, by invitation, in a number of international congresses concerned with the biochemistry of muscle, and has published many articles on this subject in the *Biochemical Journal* and other scientific periodicals

Analytical Chemistry at Birmingham

Prof Ronald Belcher

The award of the title of professor of analytical chemistry is a tribute to the work Dr Belcher has done at Birmingham in building up the School of Analytical Chemistry, which is unique in Great Britain The honour comes at an appropriate time, since he is at present the president of the Analytical Chemistry Section of the International Union of Chemistry and a vice-president of the Union Prof Belcher received his early education in Sheffield and gained his first qualifications through the Royal Institute of Chemistry After carrying out extensive researches since 1928 on coal at the University of Sheffield, he became a lecturer in chemistry in the University of Aberdeen in 1946, moving to Birmingham in 1948 Since that time a constant flow of papers has come from his group and no less than twenty-eight higher degrees have been awarded to graduates in analytical chemistry under his supervision With pupils and colleagues he has published more than 150 papers and ten well-known books, all in the field of analytical chemistry, and to these and his many editorial and committee activities he owes his world-wide reputation He gained the Ph D and D Sc of the University of Birmingham With the vast extensions of the Chemistry Department at Birmingham nearing completion, Prof Belcher and his colleagues will have greatly increased facilities for research and the training of analysts at all levels

Mathematical Physics at Birmingham

Prof G E Brown

The title of professor of mathematical physics has been conferred on Dr G E Brown, at present reader in the Department of Mathematical Physics Dr Brown, who is a citizen of the United States, studied in South Dakota State College, at the Universities of Iowa and Wisconsin, and after war service became a graduate student at Yale in 1947 and obtained his Ph D there in 1950 He was awarded the D Sc of the University of Birmingham in 1957 He went to Birmingham with a post-doctoral award in 1950, was appointed a research fellow in September 1950 and has been on the teaching staff since 1954, except for a period of study leave from January to September 1958, which was spent in the Institute for Theoretical Physics in Copenhagen He has published numerous papers on different aspects of quantum theory, particularly on relativistic electron theory, including relativistic corrections in atomic problems More recently he has done important work in nuclear theory, including a series of papers with various collaborators on the relation between the nuclear many-body problem and the 'optical model'

National Science Foundation

Dr David D Keck

THE National Science Foundation has announced that Dr David D Keck has resigned his position at the New York Botanical Garden in order to remain permanently as programme director for systematic biology at the Foundation's Division of Biological and Medical Sciences The Systematic Biology Programme receives research proposals and administers more than three hundred active grants In 1950, Dr Keck joined the staff of the New York Botanical Garden as head curator, he became assistant director in 1955 and served as acting director in 1958 From 1926 until 1950 he was on the staff of the Division of Plant Biology of the Carnegie Institution of Washington, at Stanford, California There he was a member of a research team concerned with pioneer work on the nature of plant species He is the author of many technical papers and has collaborated with Philip A Munz in writing "A California Flora" that has just come from the University of California Press

Microbiological Research

IN a written answer in the House of Commons on July 21, Mr H Nicholls, Parliamentary Secretary to the Ministry of Works, stated that since the Council for Scientific and Industrial Research announced last December its intention to encourage university research in microbiology, ten applications had been received for grants for research projects in microbiology not previously supported by the Department of Scientific and Industrial Research and all these applications had been approved

Zenith Reactor

A QUESTION was asked in the House of Lords on July 15 about the 'Zenith' low-power reactor installed at Winfrith Heath mainly to further the work of the European Nuclear Energy Authority project for research on a high-temperature gas-cooled reactor In reply, the Minister of Power, Lord Mills, said that the project would pay rent to the Atomic Energy Authority for the use of the reactor It was hoped that about half the professional staff would be provided from signatory countries other than the United Kingdom Of the total estimated cost of the project, £10 million would be contributed by the participants, the United Kingdom supplying the balance of £3 6 million and would retain ownership of the reactor and other equipment in Britain when the project was terminated The work would be carried out by the Atomic Energy Authority, but all participating countries had their say on various matters connected with the project

Chief Inspector of Nuclear Installations

IN the course of the debate in the House of Commons on July 2, when the Nuclear Installations (Licensing and Insurance) Bill was given its third reading, it was stated that the Minister of Power intended to appoint a chief inspector of nuclear installations who would be responsible for advising on the measures to be taken to carry out the Minister's responsibilities under the Act The appointment had been offered (pending the Royal Assent) to Major-General S W Joslin, who had accepted it Major-General Stanley William Joslin was educated at Hackney Downs School, Royal Military Academy, Woolwich, and the University of Cambridge He held the appointment of director of mechanical engineering at the War Office, until he joined the United Kingdom Atomic Energy Authority in 1954, and later became deputy director (personnel) of the Industrial Group As chief inspector, Major-General Joslin will be the head of the inspectorate, and one of his main tasks will be to advise on the organization and build-up of the inspectorate

Exchanges between Soviet and U S Scientists

THE U S National Academy of Sciences and the U S S R Academy of Sciences have announced the signing of a two-year agreement providing for exchange visits by research scientists of each country for periods up to one year Under the terms of the agreement, each Academy named twenty fields of specialized scientific inquiry in which its scientists wish to observe or conduct research within the host country In addition, the agreement provides that the two Academies will organize joint symposia dealing with scientific problems of current interest, assist each other in the exchange of scientific information, and on a reciprocal basis exchange invitations to important scientific meetings Implementation of these provisions will substantially increase the exchange of scientists between the two countries

Colonial Development

THE annual report of the Colonial Development Corporation for 1958 (London H M Stationery Office Pp v+69 4*s* 6*d* net) and the last over the signature of Lord Reith, who was succeeded as chairman on March 31 by Sir Nutcombe Hume, records 77 continuing projects compared with 76 the previous year Four have stopped, and of the five new projects approved, one, Federation Chemicals, Ltd (Trinidad), for the first time associates Corporation money with American technique and finance in a Colonial territory Much effort has been spent in Nigeria in seeking to bring about joint development companies in partnership with regional Governments, and it is understood that the Corporation's view that such companies have a particular importance as instruments through which Nigerians and the Corporation can share responsibility in investigating and launching development projects will be accepted Capital approved for new projects and for expansion and completion of existing ones amounted to £3 million compared with £6 million in 1957, and gross new expenditure was £6 million The report claims that the work of the Corporation has increased Colonial production of rice, citrus, pineapples, bananas, palm oil, cocoa, coffee, tea, margarine, flour, meat and fish and also of gold, silver, copper, timber, cement, manila, hemp, wattle extract, rubber, hides, tobacco, tung oil, copra, electricity, houses, factories, roads and bridges Besides assisting in the creation of such productive assets as hydroelectric installations in Dominica, St Vincent, Rhodesia and Kenya, irrigation canals in Swaziland, roads and bridges in Ghana and Nigeria, and in making more than 500,000 acres of idle land productive, direct projects of the Corporation provided employment for more than 16,000 workers

Lord Reith claims, however, that much more could have been done, and while he stresses the need for first-class management and for trusting the Corporation to use its commercial judgment in the best interests of overseas development and thus of Great Britain itself, he is strongly critical of its relations with the Government and of consequent frustration and discouragement possibly due to differences of interpretation of the Overseas Resources Development Act. Lord Reith suggests that a rapid review of the working of that Act might be helpful. He complains particularly of the extent to which applications for projects are held up, apparently through disagreement as to the nature of the work the Corporation should do and the degree of control which the Government should exercise over it. He points out that the restrictions imposed upon the future activities of the Corporation in the emergent territories will deny them the full use of its unique facilities and managerial experience at the critical transitional stage of their development, in spite of the obligation for ensuring continuing development finance in such territories which the Government appeared to recognize at the Montreal Conference.

Chinese Scientific Literature

THE Lending Library Unit of the Department of Scientific and Industrial Research is now issuing a list of current periodicals received from China. The first list (July 1959) gives the titles of one hundred periodicals which are being received regularly, and these publications can be borrowed from the Unit by approved borrowers of the Science Museum Library, provided Science Museum Library loan requisition forms are used. Twenty-one of the periodicals listed are obtained by exchange, and special attention is directed to *Scientia Sinica* (in English) and to *Science Record* (in English, French, German and Russian). The periodicals listed are annotated according to the category of readers for whom they are intended, and whether they include contents lists or abstracts in a Western European language. This first issue also includes a note on the Chinese phonetic alphabet.

Mordell's "Reflections"

CAMBRIDGE mathematicians have sometimes mitigated the austerity of their scholarship on retirement, and to this wise relaxation we owe Hardy's "Apology", Littlewood's "Miscellany" and now Mordell's "Reflections" ("Reflections of a Mathematician", by Prof. L. J. Mordell. Pp. vii+50. Montreal Canadian Mathematical Congress, Chemistry Building, McGill University or École Polytechnique, 2500 Guyard Avenue, 1959. n.p.) In this collection of short, informal essays, the author is primarily interested in explaining the point of view of the professional mathematician to fellow scholars who are not mathematicians. He is not concerned with applications, but with mathematics itself—what it is, the fascination of its æsthetics and its techniques, the difficulties and triumphs of creative work, not without some mild insinuation that the theory of numbers is the crown of mathematics. Two of his points deserve emphasis. The first is that the three cardinal virtues for the young mathematician are faith, hope and curiosity, and that the greatest of these is curiosity. Secondly, he stresses that the mathematician's task is not ended when he has solved his problem; he is under an obligation to his fellow-workers to present his results clearly and intelligibly, and must not allow the economic demand for brevity to result in obscurity. The selection of precisely the right number of steps required to support the argument, so that it shall be neither tedious nor obscure, is a matter to which the young mathematician should pay careful attention. Mordell in this connexion quotes with approval Polya's advice "if you have two things to say, say them one at a time".

Museum of Applied Arts and Sciences, Sydney

THE Annual Report of the Trustees of the Museum of Applied Arts and Sciences, Sydney, for 1957 (Pp. 20. Sydney Museum of Applied Arts and Sciences, 1959) stresses the great urgency of allocating a site for a new museum. It points out that a modern science museum requires an extensive area and building, not only to preserve and display its national treasures in an appropriate manner, but also to exhibit full-sized engineering exhibits. Within the limits of the resources of the Museum, provision was made to show the advance of science during the International Geophysical Year. Also by means of films, diagrams and models visitors were presented with the development of guided missiles and space satellites. The results of research by the staff in the field of essential oil are drawing increasing numbers of inquiries from all over the world. Since the Museum deals principally with applied science, it was always necessary to strike a balance between pure and applied research by the staff.

Further Botanical Collections

THE great tradition of travelling and collecting plants, which, among others, we associate particularly with the name of Linnaeus and his followers and adherents, is still very much alive in Sweden. A recent issue of the *Arkiv for Botanik* (4, Part 1; 1959; Kungl. Svenska Vetenskaps—Akademien, Stockholm) is of special interest in this connexion in that it contains many new floristic records based on expeditions to places of such unique interest as the Juan Fernandez Islands. Several of the contributions, on Hepaticæ (S. Arnell), Mosses (E. B. Bartram), Uredinales (I. Jørstad), relate to materials chiefly collected in the course of an expedition by the eminent Swedish botanist, Dr. C. Skottsberg, and his wife during 1954–55 to these islands. Some of the records also relate to the Falkland Islands and South America. There is also an account of Annonaceae by von Rob. E. Fries, based on specimens collected by Dr. Eric Asplund during his travels in Ecuador in 1955.

The Ciba Foundation, 1949–59

THE Ciba Foundation, founded in 1947 by the Swiss firm, Ciba, Ltd., of Basle, for the promotion of international co-operation in medical and chemical research, shows in its report for the years 1949–59 a remarkable record of success. Housed at 41 Portland Place, London, W.1, in a building designed by the brothers Adam which was built in 1778, and is now scheduled as a building of historical and architectural interest, the Foundation, through its Trustees, Executive Council and International Scientific Advisory Panel, has arranged numerous international conferences, colloquia and discussion meetings on various subjects, as well as the Ciba Foundation annual lectures and scientific-film sessions (The Ciba Foundation for the Promotion of International Co-operation in Medical and Chemical Research. Ten Years Report for 1949–1959. Pp. 1–64. The Ciba Foundation, 41 Portland Place, London, W.1). A feature of the colloquia and conferences is that they are attended for three or four days by experts in various fields of work from various countries who are invited to take part, the number attending being kept low, great importance being attached to free discussion and social contacts between the participants Other activities of the Foundation are the one-day Study Groups, which are held in honour of overseas members of the Foundation's international scientific advisory panel and similar one-day meetings, or 'Research Fora', which are held on behalf of sponsoring individual or scientific societies The Foundation also provides accommodation and hospitality for various scientific organizations Its Library includes autographed copies of works by distinguished scientific men and tape-recordings of the Foundation's meetings The Foundation, in co-operation with the Institut National d'Hygiène, Paris, offers twelve Anglo-French Medical Exchange Bursaries of £50 a month tax-free for two to four months for the study of special techniques in Great Britain and France A glance through the list given in this report of the subjects discussed at the Foundation's various meetings shows that, although the emphasis has been on endocrinology and problems of ageing, these discussions have dealt with many of the most important lines of modern medical research Results have been published in some forty-seven volumes issued by Messrs J and A Churchill, London

Oreopithecus

Since the discovery in 1872 of the lower jaw of the fossil primate *Oreopithecus* in lignite deposits in Italy, conflicting views have been expressed by various authorities on its taxonomic status, but in general there has been in the past a consensus of opinion that it represents an aberrant type of cercopithecoid monkey, showing in its dentition some approximation to the anthropoid apes The discovery in recent years by Dr J Hurzeler, of the Basle Museum, of many more specimens of this Lower Pliocene primate, including the skull and much of the post-cranial skeleton, has lent some support to the contention that it is more closely related to the anthropoid apes But Dr Hurzeler goes further than this, and has argued that the dentition and skeleton show some hominid features which suggest that *Oreopithecus* is properly to be regarded as a Pliocene representative of the very base of the hominid stem In a careful study of a maxilla with the upper dentition in the British Museum by P M Butler and J R E Mills (Bulletin of the British Museum (Natural History) Geology Vol 4, No 1 A Contribution to the Odontology of *Oreopithecus* Pp 1–26+plate 1 London British Museum (Natural History), 1959 10*s*), the authors adduce strong reasons for affinities with the anthropoid ape family but find no good evidence for a hominid relationship They regard such 'hominid' features of the dentition as have been described as probably the result of parallel evolution associated with the abbreviation of the facial skeleton and a reduction in size of the canine teeth They conclude that *Oreopithecus* should be retained in a separate family, Oreopithecidae, as originally maintained by Schwalbe (1916), and that it is probably a representative of a phyletic line which developed independently of the evolution of the modern anthropoid apes or the Hominidae The material collected by Dr Hurzeler still more recently may perhaps lead to a modification of this point of view, for according to an article which appeared in *Antiquity* (33, 131 , 1959) it is stated "on information received"—but not yet published—that the post-cranial skeleton shows some clearly marked anthropoid ape features combined with a few which could be regarded as hominid characters But a final decision on the status of *Oreopithecus* will no doubt depend on how far it is possible to make correction for the distortion by crushing which has evidently affected much of the fossil material

Floral Abnormalities in Broccoli

D R Sampson and M MacArthur have described some interesting floral abnormalities which apparently arise spontaneously in green sprouting broccoli (*Annals of Botany*, N S , 23, 211, 1959) Of the several types of abnormalities that may develop in a raceme, flowers with united sepals bearing ovules ventrally on placentae along the lines of sepal union, and pads of stigmatic tissue at the apices of the sepals, are among the most conspicuous Other curious developments include open, boat-shaped gynœcia, and irregular terminal structures suggestive of laterally united gynœcia Developmental aspects are discussed and some of their morphogenetic implications noted

Nitrate Reductase from Germinating Wheat Embryos

The isolation and purification of a soluble enzyme, a nitrate reductase, from embryos of germinating wheat have been described by D Spencer (*Australian J Biol Sci* , 12, 2, 181, 1959) This enzyme is coupled specifically to reduced diphosphopyridine nucleotide Addition of flavin adenine dinucleotide to the purified enzyme results in a threefold increase in activity Flavin mononucleotide is without effect Potassium cyanide and sodium azide cause 50 per cent inhibition of enzyme activity at 1 $6 \times 10^{-6} M$ and $2 \times 10^{-5} M$ respectively The effect of a range of other inhibitors is reported The presence of inorganic phosphate is required for maximum activity The dissociation constant (K_S) of the nitrate–enzyme complex is 3 8×10^{-4} M, and that of the diphosphopyridine nucleotide–enzyme complex is 8×10^{-6} M The pH optimum for enzymatic activity is 7 4

Climatic Changes and Secular Solar Activity

The Geophysical Institute of the Czechoslovakian Academy of Sciences has published a paper by Z Gregor and L Křivský on the long-duration changes in the climate of the Atlantic-European area as related to the secular solar activity (*Geophysical Sbornik*, No 62 1957 Russian texts, Czech and German summaries) These climatic changes, expressed by the circulation of the atmosphere and the movement of the frontal zone, lead to an increase of the average temperature in this area, and promote the recession of glaciers The changes are attributed to the secular changes in the emission of solar energy

Infra-red Absorption Bands

The measurement of the intensity of infra-red absorption bands is important both in theory for the deduction of bond moments and hence structural studies, and in practice because it is the basis of quantitative analysis by infra-red methods Until about 1946 the subject was comparatively neglected because of the scarcity of reliable instruments, but since then a considerable literature on the subject has been built up and the bibliography compiled by R G Gillis (*Australian Defence Standards Laboratories Technical Memorandum* 2 The Intensity of Infra-red Absorption Bands a Bibliography Compiled by

Dr R G Gillis Pp i + 48 Maribyrnong, Victoria Defence Standards Laboratories, Department of Supply, 1958), covering work up to the end of 1957, should be most valuable 134 references on the theory and application of intensity measurements contained in *Chemical Abstracts* are collected together with their abstracts They are arranged substantially in chronological order within the thirteen sections entitled early work (pre-1946) , general (theory) , general (experimental) , simple molecules , C—H and C—D bands , hydrocarbon analysis , O—H and O—D bands , N—H and N—D bands , ester and ketone C = O bands , steroids , C ≡ N bands , pressure broadening , and pressure-induced absorption Since the principles of quantitative analysis are now well known, references to many methods for the quantitative determination of particular compounds have been specifically omitted from the bibliography

*p*H Measurements

ANALYTICAL MEASUREMENTS, LTD , Richmond, Surrey, is supplying an analytical pocket *p*H meter which can be used to make *p*H measurements with small amounts of solution. It is complete with batteries and a case of plastic tubes of buffer solution The meter has a scale from 0 to 14 *p*H and an accuracy of 0 1 *p*H is obtainable The assembly is in a waterproof case , the electrometer tube, switch and input connector are sealed in a single unit and the weight with accessories is only 3 lb The current price is £39 18*s*

Shell Chemical Co Reorganization

CERTAIN of the operations of the Shell Chemical Co , Ltd , are to be integrated into three divisions corresponding to the three main fields in which it is engaged, namely, industrial chemicals, agriculture and plastics These changes became effective on July 1 The manager of the Industrial Chemicals Division is Mr P J March This Division deals with solvents, general chemicals, resins and detergent products The existing agricultural organization remains unchanged as the Agricultural Division under Mr H G Huckle The Plastics Division has assumed responsibility for polyolefins, polystyrene, polyvinyl chloride and synthetic rubber The manager of this Division is Mr V N Luke

Rare Earth Metals

SUCCESSFUL production of all the rare earth metals has been achieved by Johnson, Matthev and Co , Ltd , following some active research over the past few years Supplies of the rare earths in their normal form as oxides have been available in several grades of purity , however, improved techniques for the production of the metallic elements have now been brought to fruition, and all the fourteen naturally occurring elements, together with the closely related elements scandium and yttrium, are now available in a variety of forms The metals are reduced from their fluorides with lithium, calcium or lanthanum in tantalum crucibles in an atmosphere of argon, and are then re-melted in vacuum Impurities are held at a very low level and in some cases the purity is higher than has hitherto been achieved

Society for Applied Bacteriology

AT the annual meeting of the Society for Applied Bacteriology, held in London on July 8, the following were confirmed in office *Hon President,* Mr D A McKenzie , *Hon Treasurer,* Mr G Elis Jones , *Hon Editors,* Dr S E Jacobs and Dr C A E Briggs , *Hon. Publications Manager,* Mr A H Walters ; *Hon Advertising Manager,* Mr E J Mann , *Members of Committee,* Dr Eve Billing, Mr N J Butler, Prof E L Crossley, Dr J G Davis, Mr B M Gibbs, Mr D J Jayne-Williams, Dr Jane Meiklejohn, Dr G C Ware and Dr M Woodbine After eight years as hon secretary of the Society, Mr G Sykes announced his resignation His place will be taken by Dr Ella M Barnes, Low Temperature Research Station, Downing Street, Cambridge This change will take place towards the end of October

Josiah Macy, Jr , Foundation Grants

UNRESTRICTED grants amounting to 1,650,000 dollars to eleven private medical schools in support of their teaching research staff have been announced by the Josiah Macy, Jr Foundation, New York The Foundation has made unrestricted grants of 50,000 dollars per annum for a three-year period to each of eleven private medical schools for strengthening their research teaching staff, particularly in the medical science departments

National Science Foundation Grants

THE National Science Foundation of the United States has announced the award of fourteen grants totalling 1,534,500 dollars The aim is to strengthen biological research by helping to provide scientists with new or modernized facilities and specialized experimental equipment Major grants are to be awarded as follows 250,000 dollars to the Woods Hole Oceanographic Institute, Massachusetts , 171,600 dollars to the Bernice P Bishop Museum, Hawaii ; 162,000 dollars to the Marine Laboratory, University of Miami , 155,000 dollars to the California Institute of Technology , 150,000 dollars to the University of Chicago , 135,000 dollars to the Long Island Biological Association , and 105,000 dollars to the Woods Hole Marine Biological Laboratory Other recipients are · White Mountain Research Station, University of California , California Academy of Sciences , Colorado State University , University of Chicago ; University of Missouri , Marine Laboratory, Duke University, North Carolina , and the Academy of Natural Sciences of Philadelphia

The Alvarenga Prize

ON July 14 the College of Physicians of Philadelphia awarded the Alvarenga Prize for 1959 to Dr Hilary Koprowski, professor of research medicine, University of Pennsylvania, for his outstanding work on the development of a living attenuated virus vaccine against poliomyelitis The Alvarenga Prize was established by the will of Pedro Francisco DaCosta Alvarenga, of Lisbon, Portugal, an associate fellow of the College of Physicians of Philadelphia, to be awarded annually by the College of Physicians on the anniversary of the death of the testator, July 14, 1883

Carlsberg-Wellcome Travelling Research Fellowships

THE Carlsberg Foundation (Copenhagen) and the Wellcome Trust (London) announce a third series of awards of these Fellowships, which they jointly instituted in 1957 The successful candidates for 1959–60 are Mr Michael Weis Bentzon, head of the Statistical Department of the State Serum Institute, Copenhagen, and Mr John Anthony Hunt, at present working in the Medical Research Council's Research Unit for Molecular Biology at the Cavendish Laboratory, Cambridge. Mr. Bentzon will work with Prof. M. S. Bartlett in the University of Manchester on the application of modern statistical theory of biological problems and Mr. Hunt will study methods of protein chemistry with Prof. M. Ottesen at the Carlsberg Laboratory, Copenhagen.

Lalor Grants and Awards for 1960

THE Lalor Foundation has announced the programme of awards for 1960 which it is offering for research in the biological sciences. These awards are to be for support of research on the fundamental biochemical and physiological mechanisms concerned with fertility and reproduction in various forms of life. The objectives are to further the knowledge and understanding of the basic phenomena involved and to extend and develop the possibilities for effective regulation and control. The awards may range up to 8,000 dollars a year, depending upon the scope and duration of the projects approved. Preference will be given to younger members of university and college staffs with an upper age limit of 45 years. The work may be carried out at the applicant's own institution or elsewhere. The Foundation will also grant postdoctorate summer or short-term research awards at the Marine Biological Laboratory at Woods Hole, Mass., or elsewhere for appropriate projects in the fields specified. For these awards, the stipends will normally not exceed 900 dollars for a single man or a woman, 1,100 dollars for a married man working at his home institution, and 1,250 dollars for a married man with principal programme at another institution. Application and inquiries should be sent to the Lalor Foundation, 4400 Lancaster Pike, Wilmington 5, Delaware, and applications must be received by January 15, 1960.

Selby Fellowship

IT is announced that Messrs. H. B. Selby Pty., Ltd., of Australia, have placed at the disposal of the Australian Academy of Science the means to establish a research fellowship, to be known as the Selby Fellowship. The intention of the gift is to recognize that, whereas there are numerous scholarships that enable Australian graduates to proceed overseas for research experience, there is now a need for measures to bring young graduates from British and other overseas universities for postdoctoral work in Australian laboratories. The Selby Fellowship is intended as a contribution to this problem. The Fellowship may be awarded for work in any branch of physical or biological science, and is tenable at any university or research institution in Australia by applicants less than thirty years of age. In general, applicants should hold the Ph.D. degree or have equivalent status and experience, but the Fellowship will not normally be given to those who have already held a senior research award. The Selby Fellowship will normally be tenable for one full year of work in Australia. This year applications will close on November 1 with the Assistant Secretary, Australian Academy of Science, Gordon Street, Canberra City, A.C.T. In future years it is intended that applications will close about June 20.

University News

Birmingham

THE following appointments have been made: to the chair of botany, Prof. J. Heslop Harrison (for a note on Prof. Heslop Harrison's work see *Nature*, 173, 150; 1954); Dr. Brenda Manly and Dr. J. Cohen, lecturers in zoology; K. A. Redish, lecturer in mathematical physics; Dr. N. A. Dyson, lecturer in physics; Dr. F. J. Wallace, lecturer in mechanical engineering; Dr. I. R. Smith, lecturer in electrical engineering; Dr. V. G. Jenson, lecturer in chemical engineering; Dr. W. B. Morgan, lecturer in geography; R. S. Hall, Research Fellow in physics; E. A. Howson, Research Fellow in electrical engineering; R. D. Hartley, Research Fellow in mining; E. Whipp, G. E. C. Hirst Fellow in the Department of Electrical Engineering; A. T. Aldred, Research Fellow in physical metallurgy; D. W. Jones, Research Fellow in physical metallurgy.

Leeds

THE following appointments to lectureships have been made: A. W. Chronowicz (civil engineering); Dr. B. F. Salvage (electrical engineering); A. L. Yettram (civil engineering).

Sheffield

THE following appointments to lectureships have been made: P. Chadwick, applied mathematics; Dr. J. N. Murrell, chemistry; C. E. Blank, medical genetics; Dr. J. Sykes, biochemistry; Dr. J. M. Hoskins, bacteriology and virology; Dr. J. Allison and Dr. A. M. Howatson, electrical engineering; K. Littlewood, fuel technology and chemical engineering; Dr. E. W. Lee, physics; L. Lehman, dental mechanics and prosthetics; T. B. Ferguson and J. D. Stringer, mechanical engineering; W. J. M. Tegart and C. W. Hawarth, metallurgy. Dr. J. F. Wallace has been appointed senior research fellow in mechanical engineering. The title of reader has been conferred on the following: Dr. A. Garnett, geography; Dr. D. R. Davies, applied mathematics; Dr. P. L. Pauson, organic chemistry.

St. Andrews

THE following appointments have been made: to readerships, Dr. D. Bijl, lecturer in natural philosophy in St. Salvator's College, and Dr. A. J. O. Cruickshank, lecturer in electrical engineering in Queen's College. Senior lectureships are as follows: Dr. J. L. Copp, lecturer in chemistry in Queen's College; Dr. F. D. Gunstone, lecturer in chemistry in St. Salvator's College; Mr. W. McNicoll, lecturer in civil and mechanical engineering in Queen's College; Dr. A. R. Mitchell, lecturer in mathematics in St. Salvator's College; and Dr. F. Walker, lecturer in geology in Queen's College.

Announcements

FOLLOWING the death of Sir Claude Gibb, it has been announced in the House of Commons that Sir Solly Zuckerman will succeed him as chairman of the committee responsible for controlling Government-financed scientific research and development. The committee was set up to consider the techniques and management of such projects.

ERRATUM. The papers referred to in the article entitled "Water-Resources and Water-Use Survey" in *Nature* of July 11, p. 96, are wrongly described in the footnote. The correct reference number is WMO No. 82 TP 32, which is published by the Secretariat of the World Meteorological Organization, Avenue de la Paix, Campagne Rigot, Geneva.

NATURE CONSERVATION AND YOUTH SERVICE IN BRITAIN

IN the past two reports of the National Parks Commission, appreciation has been expressed of the work done by volunteer groups in clearing disfigurements in the National Park areas in Pembrokeshire, Northumberland, the Lake District and the Peak District When the Council for Nature was formed in 1958, it declared its intention of forming a volunteer group of young men and women to work in nature reserves and similar areas on tasks having the purpose of preserving the flora and fauna of the countryside The Council's purpose in this project was twofold on one hand, to help the many naturalists' trusts and other bodies in managing areas of scientific interest, and on the other, to offer young people in their spare time a task in the countryside which was worth while This project was made possible by a generous grant from the Carnegie United Kingdom Trust, and in a paper read before Section X (Assembly of Corresponding Societies) of the British Association during the York meeting, Brigadier E F E Armstrong, who has been responsible for the organization of this Volunteer Conservation Corps for the Council, described the scope of the Corps and some of the experience gained and problems encountered

In contrast to the Civilian Conservation Corps of the United States, Brigadier Armstrong pointed out that the Conservation Corps is a volunteer spare-time activity, and the tasks undertaken had to be within the capacity of a group of young men and women working for the comparatively short periods they could give in holidays and vacations Moreover, it was important that the task undertaken should have a viable ultimate scientific purpose, and should not be such that it would obviously be more usefully and efficiently done by machinery Usually the tasks undertaken were those requiring manual rather than mechanical labour and suited to a group of volunteers, aged 16–23, working for periods of one, two or three weeks In practice, the limiting factor had proved to be the financial resources, and not the availability of volunteers some 400 volunteers had come forward against the 160 places that the Corps had been able to offer on 'residential' tasks, including week-end tasks and those occupying one or more weeks Generally, the volunteers were from 'sixth formers' of schools, but university undergraduates and older members of natural history societies, 'Rovers' and 'Rangers' had also been anxious to help

For the most part, volunteers were educated and already interested in natural history, and leadership could be formed on the site of the work, though the responsibility for the prior organization of the work rested with the headquarters organizer and the members of the body for whom the work is being done

Brigadier Armstrong stressed the educational side of the work The programme always included a daily evening lecture on some topic of nature conservation, followed by discussion, and efforts were made to include a visit to some other site of scientific interest in the neighbourhood and to any Nature Conservancy or Forestry Commission establishment within range The education side had been much appreciated by the volunteers, and had clearly contributed to the success of the project The Conservation Corps had already proved the existence of a very strong desire on the part of young men and women in Britain for an opportunity to assist in preserving the flora and fauna of the countryside

Reference was made to the importance of satisfactory accommodation, for this year the Corps would have its own camp for a task exceeding a fortnight, while for other tasks accommodation had been obtained in youth hostels, a Field Studies Council hostel, a hotel and in H M S *Conway* Tasks already undertaken included clearing the dogwood and other scrub which has invaded and is overrunning the grassland slopes of Juniper Top, Boxhill, clearance work in a compartment of Woodwalton Fen to open it up for fenland flora and improve it as a habitat for the large copper butterfly, clearance of scrub in Askham Bog to show regeneration of plants and removing the top layer of vegetation to provide an area of more permanent bog conditions, clearing a path in Surlingham Broad to improve access to the centre of the Broad, and shelving down banks of ponds in Newborough Warren which had been excavated by machinery and planting suitable to consolidate these edges

Brigadier Armstrong also referred to the development of week-end or single-day tasks, particularly in areas where plenty of volunteers are available and responsibility for organization could be delegated locally Such tasks, which did not involve accommodation, were likely to be less expensive to organize and it was hoped to extend the development in future

A following paper dealt with another problem also exercising concern both to the National Parks Commission and the Nature Conservancy Breaches of the Country Code, damage to farm-land and in nature reserves is frequently done by teenagers from the big cities, seeking freedom from restrictions in the country and unaware of the dangers they themselves often run or the damage they do Mrs Edie J Green, senior instructor of the Kyndwr Scwd Mountain Training Centre, Derbyshire, described a successful attempt to enlist the adventurous spirit of a group of such boys and to guide it into useful purposes A start was made with a group of eight boys drawn both from those full of enthusiasm for outdoor activities but lacking skilled guidance, and from those responsible for vandalism, usually through sheer exuberance rather than deliberate destructiveness Following essentially the principles laid down in another sphere by Elton Mayo and Mary Follett, and applied so strikingly by Lieut -Commander A H Leighton in a Japanese re-location camp, the friendship of the boys was first won, and also the co-operation and goodwill of farmers and others in the district with whom the scheme would involve contact were secured Then the boys were encouraged to frame their own rules and ultimately they produced a set of rules for the situation more impressive than the Country Code itself, breach of which was punished, by the group's own decision, by sending the offender home In practice, the rules were rarely broken, because to the boys they made sense

From this it was an easy step to the acceptance of the Country Code itself, and the boys were often heard talking to their contemporaries about what should or should not be done in the country, and Mrs Green suggested very reasonably that this is likely to have a far deeper effect than police warnings or slogans on the notice boards With this went a changed attitude to farmers Getting to know the farmers and understanding what farming meant changed the attitude of the boys into one of respect and co-operation the farmer who had provided the site for the camp found his shippen cleaned out for him and a boy who admitted to knocking down dry-stone walls for years was found attempting to rebuild one

Such changes alone would justify the continuance of such training camps from the point of view of the national parks and nature reserves alone, but the scheme also provided a definite programme for training the boys in climbing, in mountain rescue and in first-aid—at their own request Here again the boys, from being a liability or a nuisance on the hills, became competent members of a mountain rescue team, and every challenge to endurance was met with enthusiasm The experimental period described by Mrs Green also showed the value of the scheme in developing the personalities of the boys. Much clearly depends on the quality of the staff, and there is also the matter of equipment, but the new training centre which opened in September 1959 offers a first-class mountaineering course for 5*s* affiliation fee and 2*s* 6*d* at each school, and thirty boys are being taken

APPLIED MATHEMATICS AND THEORETICAL PHYSICS AT CAMBRIDGE

A DEVELOPMENT in the University of Cambridge which will be of interest generally is the formation, from October 1, 1959, of a Department of Applied Mathematics and Theoretical Physics The Department comes within the Faculty of Mathematics, and embraces the present teaching staff and research students on the applied side of the Faculty Academic staff at Cambridge traditionally divide their time between centralized university lecturing and supervision of research students (as university lecturers, readers, etc) on one hand, and informal teaching of undergraduates in their own college (as Fellows) on the other This arrangement undoubtedly has advantages for undergraduates, but it has not been without some unfortunate consequences for research in a number of subjects The various colleges provide their official Fellows with rooms, and the existence of this accommodation has retarded the development of centralized departments and buildings with adequate facilities for research Teaching and research in the experimental sciences are impossible without a properly equipped laboratory, and these subjects were the first to be provided with central University buildings Less obvious perhaps, but no less real, is the need for theoreticians to meet and work together in these days of rapid scientific developments and enlarging horizons. The formation of a Department of Applied Mathematics and Theoretical Physics at Cambridge is a recognition of this need, and is viewed as an administrative step towards the provision of central office accommodation and research facilities for the members of the Department. When that is achieved. an anomaly peculiar to the University of Cambridge will have been removed

There are two novel features of the new Department The first is that, as implied by the name, the Department includes both 'classical' and 'modern' aspects of theoretical physics and engineering science, in contrast to the usual plan in which applied mathematics and theoretical physics fall in separate university departments This unity was suggested by the existing practice of teaching both applied mathematics and theoretical physics in the Mathematical Tripos, and it was in any event felt to be appropriate The customary division between applied mathematics and theoretical physics is scientifically rather arbitrary (being prompted, perhaps, by the fact that in most universities applied mathematics is linked with pure mathematics and theoretical physics with physics) and is often unfortunate in its effects Recent work on plasma physics and magneto-gas-dynamics has shown how much the two subjects have in common and how artificial is the division between them, and the older fields of theoretical astronomy and astrophysics have long illustrated the same point The staff at Cambridge who will comprise the new Department are eighteen in number, and are engaged on work in elementary particle and field theory, nuclear physics, astrophysics, plasma dynamics, fluid mechanics and geophysics

The second novel feature is the provision that the head of the Department shall be appointed for five years at a time from among the more senior people in the Department This represents a deliberate departure from the practice in British universities of having a head with life tenure, usually the sole professor, or, where there is more than one professor, the one of greatest scientific distinction, and is more like the arrangement in many American universities The disadvantages and risks of having a permanent head are well known, the health and fate of the department are tied to the administrative ability and capacity for leadership of one person for many years, the growth of a hierarchial structure may be encouraged, the talents of a rising leader may not be given full scope, and so on There are also advantages, which may be more important in some circumstances, but there was a strong feeling at Cambridge that a more flexible scheme was desirable for the new Department A period of five years was chosen as being long enough to allow the head of the Department to formulate and carry through any schemes which may be close to his heart, and short enough to be regarded as only a temporary interruption of personal research The regulations allow re-appointment of a person for further periods of five years This experiment in administration of a university department will be interesting and may have its lessons for other departments

The first head of the Department is Dr G K Batchelor, reader in fluid mechanics He is known for his work on the theory of turbulence and other branches of fluid mechanics, for which he was elected a Fellow of the Royal Society in 1957. Dr. Batchelor was born in Melbourne in 1920 and received his first degree from the University of Melbourne in 1940. Later he went to Cambridge, where he was elected a Fellow of Trinity College in 1947 and awarded an Adams Prize in 1951. He is editor of the Cambridge Monographs on Mechanics and Applied Mathematics and of the *Journal of Fluid Mechanics*.

ENZYMES

WAGENINGEN, situated on the Rhine in eastern Holland, contains 22,000 inhabitants, and about seventy institutes for scientific research. About one-half of these institutes form part of the State Agricultural University of Wageningen, while the other half are government or private institutes.

In these pleasant surroundings, a highly successful conference on enzymes was held by the University of Wageningen during April 6–9. The organizing committee was under the chairmanship of Prof. H. J. C. Tenderloo, with Dr. H. Veldkamp as secretary.

An introductory lecture was given by E. C. Slater (Amsterdam), who emphasized the central place of enzymology in biochemistry. In his view, it is enzymology which gives biochemistry its own methodology, and its own manner of thinking. (Later in the conference, H. Booij (Leyden), speaking as an 'angry young man', provided the necessary corrective against any over-enthusiastic adoption of this proposition by pointing out that other fields of biochemistry existed.) Although there are many different enzymes, the number of different reaction types catalysed by enzymes is quite small. Life, as we know it, involves comparatively few chemical tricks, which are used over and over again, and the aim of biochemistry is to systematize our knowledge of these tricks. A significant step forward in the systematization of enzymology was the appearance in 1958 of the book "Enzymes", by M. Dixon and E. C. Webb. Studies of the mechanism of enzyme action by kinetic and isotopic methods, and by direct chemical studies in which the enzyme is used as a reactant, have confirmed the suggestion made by Michaelis and Menten in 1913 that the enzyme reacts with at least one of the substrates to give an intermediate enzyme–substrate compound. However, in many cases the intermediate enzyme–substrate compound contains only a part, sometimes a small part, of the substrate. This lecture also dealt with the uses which have been made of isolated enzymes as tools in other investigations, in particular in analytical procedures and in the determinations of the structures of compounds isolated from natural materials, such as coenzyme A.

C. de Duve (Louvain) reviewed the recent knowledge of the localization of enzymes within the cell, which has been gained by fractionation of cell homogenates, particularly by differential centrifugation. He pointed out that although the cytologist would regard the preparation of a tissue homogenate as a brutal disruption of the cell, this homogenate is able to carry out very many reactions, and it is possible to localize different reactions in different cell organellæ which can be isolated from the homogenate. He dealt at length with the theoretical basis of the various methods of separation which have been used, and discussed their advantages and disadvantages. The use of 'marker' enzymes for the main fractions of the rat-liver cell nucleus, mitochondria, microsomes and 'soluble' fraction has led de Duve to the discovery that many hydrolytic enzymes are present in granules a little smaller than mitochondria which he has named lysosomes. More recent work using the technique of density equilibrium in heavy water has suggested that at least two enzymes (uricase and catalase) are present in yet another type of granule. The enzymes within the lysosomes are inactive towards their substrates unless the granules are destroyed mechanically or by suspension in hypotonic solution. The lysosomes also discharge their enzymes into the cell when the latter becomes anaerobic, thus promoting autolysis of the cell.

P. Desnuelle (Marseilles) spoke about the chemical structure of proteins and mechanism of action of proteolytic enzymes. He pointed out that although the chemical structures of insulin and of the polypeptides melanocyte-stimulating hormone and adrenocorticotrophic hormone are now established, the reason for the activity of the whole molecule is not yet known. He discussed what is known about the primary, the secondary and the tertiary structures of proteins, emphasizing that although other structures are theoretically possible, the open-chain is the only type which has been clearly demonstrated. Desnuelle described recent work on the activation of the precursors (the -ogens) of the pancreatic proteolytic enzymes, which has shown the importance of limited proteolysis in this process. Actually, the activation of chymotrypsin and trypsinogen is brought about by the splitting of a single bond. But this splitting is likely to be the first and necessary step for deep changes in the tertiary structure of the precursor, bringing two or three residues at the right position in space for building an 'active centre'.

E. C. Webb (Cambridge) surveyed the properties of the various coenzymes, prosthetic groups and activators of enzymes. He pointed out that metals sometimes act as carriers, sometimes promote the combination of the enzyme with the substrate. The effects of anion activators were discussed in relation to his own recent studies of the activation of arylsulphatase by chloride.

A discussion between Dr. Webb and Prof. Slater on whether a valid distinction could be drawn between a coenzyme and a prosthetic group led to the agreed definition that a compound acts as a coenzyme if during the course of its catalysis of the reaction it reacts first with one enzyme and then with another, and as a prosthetic group if it remains bound to the one enzyme during the course of the reaction. The same substance can in different reactions act as a substrate, a coenzyme or a prosthetic group.

Sir Rudolph Peters (Cambridge) discussed enzyme inhibitors, illustrating the different types by reference to carbon–fluorine compounds (for example, fluorocitrate), arsenicals and organo-phosphorus compounds. The recent studies at Babraham on the mechanism of the inhibition of aconitase by fluorocitrate were presented In the discussion of arsenical inhibitors, emphasis was placed on the different actions of monosubstituted (for example, lewisite, mapharside) arsenicals, which inhibit pyruvate oxidation, and disubstituted (for example, diphenylchlorarsine) compounds which inhibit isocitric dehydrogenase, as well as on the practical application of 2,3-dimercaptopropanol in reversing the inhibition by arsenicals

The organo-phosphorus inhibitors were discussed in relation to their action on cholinesterase, and to the reversing effect of pyridine-2-aldoxime methiodide As an example of antimetabolites, Sir Rudolph discussed the antagonism of the effect of serotonin by 1-benzyl-2,5-dimethyl-serotonin

F Dickens (London) discussed the regulation of enzymic reactions within the cell with special reference to carbohydrate metabolism Regulation can be provided by structural barriers within the cell, but also by enzymic mechanisms which do not require structural separation of reactants Examples of the latter type are given by (1) control of rate of mitochondrial respiration by the concentrations of inorganic phosphate and adenosine diphosphate , (2) 'feedback' by inhibition of the enzyme by the product of the reaction, for example, inhibition of hexokinase by glucose-6-phosphate , (3) the existence of different mechanisms for breakdown and synthesis, for example, the equilibrium of the uridine diphosphoglucose pathway of glycogen synthesis is much more favourable to synthesis than is the reversal of the phosphorylytic breakdown Dickens directed attention to situations where the pentose phosphate pathway is particularly active in relation to glycolysis, for example, in the lactating mammary gland, where its function is probably to provide reduced triphosphopyridine nucleotide for fat synthesis, and in the lens where its function is possibly to provide the same compound to keep glutathione reduced

H Chantrenne (Brussels) concluded the conference by a discussion of the present status of the investigation of the mechanism of protein synthesis in general, and of enzyme synthesis in particular He pointed out that the earlier sharp distinction between adaptive and constitutive enzymes has been abandoned The recent work of Ingram on abnormal hæmoglobins has shown that even the fine details of the protein structure are controlled by the gene A mutation of a single gene causes a change of one amino-acid in the polypeptide chain It is conceivable that the deoxyribonucleic acid of the gene contains the information which determines the sequence of amino-acids in the protein chain This information must be transferred to the ribonucleic acid in the cytoplasm, where the protein is synthesized The function of the inducer, the presence of which is necessary for formation of an enzyme, is not known However, it has been shown that it acts in catalytic amounts, not autocatalytically This suggests that it acts on an enzyme-synthesizing mechanism which is already present, perhaps in an inhibited form In the discussion of this paper, Desnuelle pointed out that enzyme activity requires a specific configuration (tertiary structure) of the polypeptide chain The native form of an enzyme is a unique, unstable structure among many more stable structures It is, therefore, likely that not only the arrangement of the residues along the chains but also the specific folding of these chains are gene-controlled This must be taken into account in any consideration of enzyme synthesis

An unusual feature of this conference which had much to recommend it was that the programme called for only two speakers each day, one in the morning and one in the afternoon This enabled the speakers to give a long introduction (about 45 min) for the benefit of non-specialists, before a coffee or tea break, after which the speaker continued for a further 30–45 min A discussion then followed E C SLATER

ENERGY TRANSFER WITH SPECIAL REFERENCE TO BIOLOGICAL SYSTEMS

THE mechanisms by which energy may be transferred from one atom or molecule to another have become a prominent theme of chemical kinetics, photochemistry and radiation physics—as well as of many biological processes The same fundamental processes and many of the outstanding problems are common to each of these sciences, and those of biological systems, in particular, depend for their solution on development in other fields The efficiency and generality of energy transfer between molecules has been fully appreciated only quite recently, and the discussion on this subject, which was held by the Faraday Society at the University of Nottingham during April 14–16, was one of those timely meetings for which the Society is noted It was attended by two hundred physicists, chemists and biologists, about one-quarter of whom were from overseas

The discussion was divided into two parts, the first concerned with energy transfer processes in general and the second with their occurrence in biological systems After the president, Dr E W R Steacie, had welcomed the overseas visitors, the Spiers Memorial Lecture on "Transfer Mechanisms of Electronic Excitation" was delivered by Prof Th Forster, of the Technischen Hochschule, Stuttgart This provided an excellent introduction to the first part of the discussion, which was concerned almost entirely with this topic The transfer of electronic excitation energy from one molecule to another can be a very efficient process which may occur, not only at every encounter, but even over distances of 50 A or more Apart from the 'trivial' process involving emission and re-absorption of light, this transfer can proceed by a radiationless mechanism known as resonance transfer, the interaction between the molecules being one of dipole–dipole coupling and not overlap of electron orbitals which is significant only at much smaller distances The process is often also referred to as the Forster mechanism, and Prof Forster gave a clear account of the quantitative theory which he, principally, has developed He discussed the application of the theory to forbidden transitions, transfer within one molecule and between like molecules, and pointed out that conditions for excitation energy transfer are very favourable in biological systems since Nature often prefers a high local concentration of absorbing matter

The first four papers of the discussion were all concerned with electronically excited organic molecules Prof G Porter and Dr M R Wright (University of Sheffield) discussed processes of deactivation involving change of multiplicity In particular, they presented rate constants for the decay of triplet states of aromatic molecules in solvents of varying viscosity and in the presence of paramagnetic molecules and ions and gave an interpretation of the latter process in terms of overall spin conservation rather than magnetic perturbation of spin-orbital coupling Dr A Weller (Technischen Hochschule, Stuttgart) described his work on the reactions of excited singlet state molecules, with particular reference to acid-base equilibria and proton transfer in the excited state Dr B Stevens (University of Sheffield), in the only paper dealing with the vapour phase, described experiments which showed that transfer of energy from electronically excited benzene to anthracene occurred over an average distance of 7 6 A Dr E J Bowen (University of Oxford) described fluorescence studies of the excited singlet states of anthracene derivatives, with particular reference to the influence of temperature and solvent viscosity The data indicate that two processes of radiationless conversion—probably to triplet and ground state—are operative

There was much discussion following these papers, most of which was about radiationless transitions and particularly the effect of viscosity upon them Prof Porter had interpreted this effect in terms of different configurations of the two states, and Dr Bowen's explanation involved the attainment of a certain amplitude of vibration Prof H C Longuet-Higgins (University of Cambridge) thought that it was the removal of energy by the solvent which was important and that the greater efficiency of solvents of low viscosity was a result of their having the lower-frequency components necessary for this transfer Dr D H Whiffen (University of Birmingham) suggested that it is molecular rotation which is important and that a time-dependent mixing of singlet and triplet states is introduced by interaction between rotation and spin-orbit coupling Prof J D Bernal (Birkbeck College, London) pointed out the importance of structure and the inadequacy of viscosity as a measure of microscopic properties—a point which was emphasized by other speakers No general agreement was reached on these alternative theories in spite of the very valuable discussion

The second scientific session began on the morning of April 15, with four papers on electronic energy transfer in solution Dr F H Brown, Dr M Furst and Prof H P Kallman (New York University) gave an account of their extensive work on energy transfer in rigid and liquid organic scintillator systems induced both by light and by ionizing radiations In these solutions as much as 10 per cent of the energy absorbed by the bulk material is emitted by the solute, and three mechanisms, in addition to the radiative one, are involved under various conditions These are (*a*) material diffusion transfer (in liquids only) , (*b*) migration transfer , (*c*) single step transfer Dr J B Birks and K N Kuchela (University of Manchester) described similar studies in polystyrene solutions as a function of wave-length At concentrations greater than 10^{-4} molar the transfer was found to be non-radiative Prof M Burton and H Dreeskamp (Notre Dame University) described the measurement of luminescence decay times in scintillator systems by a method utilizing X-ray pulses of about 10 mμsec duration and concluded that the measured decay times were characteristic of excitation transfer processes Prof M Dole (Northwestern University, U S A) and Dr T F Williams (Atomic Energy Research Establishment, Harwell) described further studies of the disappearance of unsaturated linkages on γ irradiation of polyethylene, the high *G* value of which shows that energy transfer processes must be operative

In the discussion on these papers, Prof Kallman pointed out that the life-time of anthracene vapour molecules is shorter by an order of magnitude than that found in condensed phases, which Bowen suggested might be due to the fact that emission involves higher vibrational states of the excited gaseous molecule Dr Stevens said that the longer measured life-time in condensed media was probably due to re-absorption effects, a view shared by Birks, who emphasized that the 'molecular' life-time in condensed phases is as short as that found in the gas Prof Burton warned against over-confidence in values obtained by the phase-shift technique, since analysis of the data assumed an exponential decay which may not always be observed

Dr A Szent-Gyorgyi introduced the papers on "Energy Migration in Biological Systems" with a summary of the various ideas that have been introduced in the past fifteen years semiconductivity, resonance energy transfer and electron transport Dr Szent-Gyorgyi dealt more specifically with the electron flow in the respiratory chain and introduced a suggestion of his own, namely, that the partial charge transfer complexes that have been intensively studied during the past few years are the first steps in the one-electron oxidation processes that Michaelis first postulated

These various aspects of energy transfer were dealt with in detail in the papers that followed M H Cardew and Prof D D Eley (University of Nottingham) reported measurements on the semiconductivity of amino-acids, hæmoglobin and globin Their findings of small conductivity with activation energies of the order of 3 eV are in agreement with the values expected for a hydrogen-bonded CO HN system R Mason (University College, London) described some possible instances of charge transfer in proteins, which have not yet found empirical foundation Dr G Weber and F J W Teale (University of Sheffield) reported on energy transfer in the hæm proteins which results in the quenching of the tryptophan fluorescence of the native proteins and of the fluorescence of a conjugated group in hæm–protein conjugates The results, which are in general agreement with Forster's theory, permit some conclusions about the distribution of the hæms on the surface of hæmoglobin A paper by Prof Q H Gibson (University of Sheffield) described how hæmoglobin formed from CO-hæmoglobin by a light flash had a much greater reactivity towards carbon monoxide than the ordinary hæmoglobin into which it reverted spontaneously with a rate of 200 $\sec^{-1}$

Four papers dealt with energy migration in photosynthesis The background to the problems was presented by Prof B Rabinowitch and Dr S S Brody (University of Illinois), who pointed out the unique structural features of the chloroplast as revealed by the light and electron microscopes and the difficulty, if not the impossibility, of reproducing these features in our simple model systems When the probable ways of energy migration in the chloroplast are considered the resonance transfer among some 200 chlorophyll molecules forming a photosynthetic unit appears the most likely Prof R Lumry (University of Minnesota) presented work by himself, J D Spikes and B Mayne in which simultaneous measurements of Hill reaction velocity and fluorescence yield were carried out The parallelism of the two phenomena strongly favours the idea of a trapping centre to which the energy is transferred by resonance after its absorption by chlorophyll and where it is utilized in competition with the fluorescence and other radiationless deactivation processes A paper by Dr L N M Duysens and J Amesz (University of Leyden) dealt with the quantum requirements of diphosphopyridine nucleotide in photosynthesis From this paper, as well as the previous work of Dr Duysens on the oxidation of cytochromes, and from recent data that Prof Britton Chance and T Yonatani (University of Pennsylvania) presented in the course of the discussion, in which fast simultaneous recordings of cytochrome oxidation (by absorption) and diphosphopyridine nucleotide reduction (by fluorescence) were obtained, it appears now certain that the simultaneous oxidation of cytochromes and reduction of diphosphopyridine nucleotide are among the earliest events in photosynthesis Prof R Livingston (University of Minnesota) and Prof A Terenin, E Putzeike and I Akimov (University of Leningrad) dealt with properties of isolated chlorophyll, namely, the quenching of the triplet state and the photoconductivity, respectively Dr W A Hagins (National Institutes of Health, Bethesda) and W H Jennings (Duke University, U S A) presented experiments which showed the localization as opposed to migration of the excitation in the retinal rods, while M J Cowan, J M F Drake and Dr R J P Williams (University of Oxford) examined chelates of iron as models for the understanding of the variations in spectrum and redox potential of the cytochromes

A paper by Prof Britton Chance and E L Spencer (University of Pennsylvania), which described the rapid establishment of redox equilibria in the cytochromes of cells and cell particles at the temperature of liquid nitrogen, was interpreted by the authors as suggesting a solid-state mechanism of electron flow among the cytochromes

Prof D E Green (University of Wisconsin) concluded from the analysis of linked respiratory chain reactions that the electron transport is essentially a solid-state process occurring in a lipid phase , but the discussion that followed this paper showed that the evidence was not regarded as in any way conclusive

In a discussion of energy in the biological systems, adenosine triphosphate could not be omitted Although no paper dealt specifically with the properties of adenosine triphosphate, these were the subject of a lively discussion Briefly, some speakers thought that adenosine triphosphate has had greatness thrown upon it by the accident of evolution, a distinction which may just as easily have fallen on its humble cousin pyrophosphate Others believed that the rest of the molecule will be found to be indispensable in energy transfer Prof J A V Butler (University of London) summarized the evidence for the first view Dr J H Turnbull (University of Birmingham) put forward the case for the latter

The past twenty years have seen great improvements in the methods that reveal the purely structural features of biological systems Because of their success we have come to look for explanations of biological events in terms of structural factors alone The energetic aspect is equally important and indeed complementary to the structural, and this meeting rendered a good service to the biological sciences by bringing attention to this often neglected point

G Porter
G Weber

HEATING BY ELECTRON BOMBARDMENT

Electron bombardment heating is produced by accelerating electrons from a thermionic cathode on to a specimen, by means of a d c voltage Simple focusing of the electron paths enables the heating to be highly localized and melting is achieved with very small power requirements These facts, together with an ease of power control and the necessity for vacuum operation, explain the preference for heating by electron bombardment in some applications Although used for very many years it is only recently that this method of heating has become more widely known through its application to the melting of refractory metals for the purpose of floating-zone melting[1], welding[2,3] and evaporation[4] The growing interest in this technique was shown by the attendance of one hundred and sixty visitors, from British and overseas laboratories, at a symposium on "Electron Bombardment Floating-zone Melting and Allied Electron Bombardment Techniques", held at the Services Electronics Research Laboratory, Baldock, Herts, on March 10

Several papers on electron bombardment floating-zone melting were given In this method, a rod of the material being purified is held at both ends in a vertical position and a molten zone is induced in it by bombarding it with electrons from a circular cathode The molten zone is held stable by surface tension and this imposes an upper limit[5] on the maximum zone length, and hence diameter, of the specimen to be zoned Relative longitudinal movement between the cathode and rod moves the zone along the rod and zone-refining takes place The purified rod often becomes a single crystal Metals sometimes out-gas violently when melting for the first time in a vacuum, and a bombardment-current controller[6,7] is necessary to stabilize the current, which tends to fluctuate under these conditions Whereas vacuum operation is advantageous when zoning reactive metals, it has the accompanying disadvantage that considerable material may be lost by evaporation This has led most experimenters to use zone travel speeds which are too fast for segregation of impurities, and purification is obtained mainly by evaporation of the lower melting point impurities from the molten zone and by out-gassing *in vacuo*. A criticism of the method is that contamination of the specimen by the cathode can occur and is occasionally detected. This can sometimes be overcome by using a cathode of the same material as the specimen, for example, tantalum, rhenium, or by designing a cathode system which 'hides' the cathode from the molten zone. No speaker reported any experiments on this aspect.

A. Calverley (Services Electronics Research Laboratory, Baldock, Herts) described an improved electron bombardment apparatus[8] which overcame the limitations of poor operating vacuum, visibility and speed range of his earlier apparatus[6]. The main features of the new apparatus are similar to those of the Services Electronics Research Laboratory silicon crystal puller[9], and zone-refining of refractory metals and semiconductors can be done in a vacuum of $\sim 10^{-6}$ mm. mercury and sometimes better. Of great practical value is the ability to move vertically up or down that part of a specimen below the molten zone during the zone-refining operation. This enables variations in the diameter of the specimen, which occur during preliminary out-gassing, to be corrected and it can also be used for determining the length of the molten zone, for with some metals it is difficult to see the boundary between the solid rod and liquid zone. With low melting-point metals such as aluminium, gold and copper, stable zones are difficult to maintain, but no difficulty is experienced with the more refractory metals. Work with the earlier apparatus was of an exploratory nature and single crystals of tungsten, rhenium, tantalum, molybdenum, rhodium, niobium, iridium, ruthenium, platinum and nickel were made ranging in size from 2–5 mm. diameter and up to 18 cm. long. The properties of these crystals are often found to be much closer to those of a perfect metal than was the case with the best specimens previously available. For example, zone-melted molybdenum was found[10] to have the same tensile ductility at − 196° C. as arc-melted molybdenum at − 30° C., and the superconducting properties of tantalum prepared in this way were found to be quite close to those of an ideal superconductor[11]. At the moment, work with this apparatus is concentrated on producing pure crystals of tantalum, vanadium and niobium for superconductivity studies, these metals being obtainable with Vickers hardness numbers 68, 79, and 38 respectively. The smallest specimen so far zoned is a 0·060 in. diameter tantalum rod. With alloys, the ability to zone-melt them depends on the vapour pressure of the constituents at the melting point of the alloy. Thus whereas tantalum–niobium alloys may be zoned, tantalum–vanadium alloys of high tantalum content cannot be melted without almost complete evaporation of the vanadium. Although possessing a high resistivity at room temperature, boron can be zone-melted providing a short electrical conduction path is maintained for the initial heating of the specimen, that is to say, if the bombarded region is within 2–3 cm. of the specimen holder. Once the temperature of the boron rises, its resistivity drops and normal zoning can take place. Boron is prone to thermal shock fracture so that heating, cooling and traversing of the specimen has to be done slowly.

F. O. Jones (Associated Electrical Industries, Ltd., Research Laboratories, Aldermaston) has prepared molybdenum–rhenium (50/50) and uranium–zirconium (70/30) alloys and concludes that, providing the vapour pressure of a constituent of an alloy is less than 10^{-3} mm. mercury, the alloy can be zone-melted without undue loss. A description of preliminary work on molybdenum–rhenium alloys was given by A. Lawley (University of Pennsylvania). His apparatus differs from that of the other speakers at the symposium in that it is a typical bell-jar system with all components mounted on a common base-plate.

Molybdenum crystals up to ½ in. in diameter have been grown by J. A. Belk (Armament Research and Development Establishment, Fort Halstead), moving the zone up a rod of swaged arc-cast material. Their axes were in the section of the unit stereographic triangle bounded by (001), (101) and (112). Tensile tests showed an absence of a sharp yield-point at the pure end, and there was a reduction of carbon from 0·008 to 0·002 weight per cent. A more sensitive method of analysis is required before any conclusions of the movement of carbon by zone-refining could be drawn. The zone-melted material showed very much lower impact transition temperatures than arc-cast molybdenum, both in single crystal and polycrystalline form. For a carbon content of 0·002 weight per cent the values were − 140° C. and − 50° C. respectively. Alloys of molybdenum with tungsten had been produced either by sintering and zone-melting a powder compact, or by melting a molybdenum rod with a close wound helix of tungsten wire. Some preliminary experiments on electron beam melting[12] were reported. In this technique, molten drops from the lower end of a bombarded rod are allowed to fall into a cooled crucible and ingots of large diameter of vacuum-melted material are produced in this manner. The experiments indicated that the power requirements were at least double those required for floating-zone melting. Out-gassing of the rod assumed much greater importance due to the increased rate of melting, and an emission-current limiter was required in addition to the normal type of emission-current controller.

F. O. Jones described his work on carbides and has found that titanium carbide (TiC) and tungsten carbide (WC) decompose at temperatures lower than their melting points. Tungsten carbide (W_2C) melted but decomposed with loss of carbon, and tantalum carbide (TaC) partially melted but also decomposed with loss of carbon. A. Calverley has found that vanadium diboride likewise decomposed with loss of vanadium.

Work on cobalt has been carried out by H. Uwents (Rijks Universiteit, Gent). After 10 passes at a zone speed of 30 cm./hr. on a 0·5 cm. diameter cobalt rod, he obtained a specimen which, after etching, revealed a small number of relatively large grains. X-ray diffraction photographs on either side of what appeared to be grain boundaries yielded the same diffraction patterns, from which he concluded they were in fact sub-boundaries. It seems possible to grow single crystals of materials which have a transformation point, by zoning at temperatures slightly higher than the transformation point.

The contribution of D. W. Rhys (Mond Nickel Co., London) was concerned with the electron bombardment floating-zone melting of platinum, ruthenium, rhodium and iridium, interest in this technique for the last three metals resulting from the lack of ductility normally encountered at room temperature. Analyses of a platinum bar zone-melted twelve times at 60 cm./hr. showed that major purification occurred by preferential evaporation of impurities, but there was nevertheless evidence of zone segregation, though at this high rate of traverse the process was inefficient. Contamination of platinum by tungsten from the filament can occur, and in some instances the product may be inferior to the starting material. Ruthenium single crystals prepared by the method can be bent readily but have not yet been cold worked successfully, and analyses of zone-melted bars have shown that purification occurs chiefly by preferential evaporation. A rhodium single crystal bar prepared by zone-melting could be cold swaged to a 90 per cent reduction in area but on subsequent annealing became polycrystalline and possessed negligible cold ductility[13]. Iridium single crystals prepared by the method are also more ductile than the polycrystalline material and, in this metal, zone segregation of nickel was observed, though the majority of impurities were reduced by preferential evaporation.

W. P. Allred (Battelle Memorial Institute, Ohio) also reported on the zone-refining of the platinum-group metals. He finds that zone speeds of 7.5 cm./hr. give little segregation of impurities whereas a speed of 1.25 cm./hr. gave very effective segregation, reducing most of the impurities below the spectrographic limit. Vacuum fusion analyses show the oxygen, hydrogen and nitrogen content to be as low as from 7 to less than 0.2 p.p.m.

One cannot bombard an insulator continuously with electrons because the electrons are unable to escape from the bombarded region, and the potential difference between cathode and target is reduced to zero. To overcome this difficulty, the insulator is bombarded at a voltage such that the ratio of secondary to primary electrons is greater than unity, and a secondary electrode is arranged to collect the secondary electrons. A communication was sent to the symposium by T. Bridges and R. Strnad (Bell Telephones Laboratories) describing their work on zone melting of single-crystal sapphire rod 0.1 in. in diameter. They find that the bombarding voltage is restricted by the above condition, the vapour pressure is high and power requirements for a completely molten zone are much higher than those for surface melting only.

Talks on other applications of heating by electron bombardment followed those on zone-melting. G. W. Warren (General Electric Co., Research Laboratories, Wembley) described the out-gassing of molybdenum in the solid state at a pressure less than 10^{-7} mm. mercury. The molybdenum specimen and bombarding system are mounted in a glass envelope which is baked and sealed-off from the pumping system after firing a barium getter. The air-cooled barium film absorbs any gas evolved from the molybdenum, which after heating for 8 hr. at 2,100° C. has an oxygen content of 1 p.p.m.

With floating-zone melting, a rod which is held at the ends only can only support one molten zone. To obtain the advantages of multiple-zone melting, P. le Couteur (General Electric Co., Research Laboratories, Wembley) used horizontal zone-melting to purify germanium. Focused electron bombardment enables narrow zones, another pre-requisite of efficient zone-refining, to be obtained. The use of a vacuum instead of a gas ambient has further lowered the ultimate impurity distribution.

Analysis of zone-refined specimens has placed fresh problems on the analyst. C. A. Parker (Admiralty Materials Laboratory, Holten Heath) reviewed the present methods available for analysing high-purity materials. One of the main problems is to obtain reagents which are as pure as the material being analysed. To avoid the use of reagents, one can either use emission spectroscopy or solid-source mass spectrometry and these have in favourable cases a limit of detection of 1 in 10^8. To investigate impurity-levels lower than this it is necessary to label the impurity atom within the sample before carrying out the analysis. The most commonly used method is to expose the sample to a flux of thermal neutrons by inserting it into an atomic reactor. The atoms become radioactive and impurities can be separated out by chemical treatment. Any contamination by corresponding impurities in the reagents has no effect on the subsequent Geiger counter reading. The sensitivity for this type of analysis may be as low as 5×10^{-12} gm., but unfortunately for some elements, either the neutron absorption is too low or the isotope produced has too short a life-time. However, proton activation is being developed as an alternative to neutron activation for some of the light elements. The principle here is the same, but instead of labelling the impurity atoms by irradiation with neutrons, they are exposed to a beam of high-energy protons from a cyclotron. Using this method quantities of boron in silicon can be determined down to 1 part in 10^9. Activation analysis by protons and other particles such as deuterons is still in its infancy, but it seems likely that methods for the determination of other light elements, including oxygen and nitrogen, will be developed in due course.

The ease with which a molten drop of metal can be produced on the end of a vertically suspended rod using electron bombardment heating had made possible the determination of the surface tension of refractory metals at their melting point. A. Calverley described his drop weight surface tension measurement of liquid tungsten[14]. His value of 2,300 dynes/cm. is approximately 380 dynes/cm. less than Taylor's estimated value[15]. A solitary determination for tantalum gave 2,020 dynes/cm., which is 310 dynes/cm. less than Taylor's value. However, J. C. Kelly (Atomic Energy Research Establishment, Harwell) has used the sessile drop method for one determination only and obtained a value for tantalum which is in agreement with Taylor's value.

J. C. Kelly described the evaporation of thin films of tantalum and zirconium[4] from a pendant drop on the lower end of a vertical rod. A simple arrangement of focusing plates enables contamination by the cathode of the drop or the target to be avoided. He has observed that, above a certain temperature, oscillations of the pendant drop occur. The rate of evaporation from pendant drops bombarded with electrons is the subject of a recent paper by Heavens[16]. Its application to 'Evaporion' pumps was discussed by L. Holland (Edwards High Vacuum, Ltd., Crawley, Sussex).

A silicon crystal pulling furnace using heating by electron bombardment was described by D. B. Gasson (Associated Electrical Industries, Ltd., Aldermaston). A central pool of molten silicon in a randomly shaped silicon charge resting on a water-cooled hearth is maintained by beams of electrons from four guns situated approximately 12 in. above the silicon to reduce mutual contamination. Each beam can be focused individually and its power varied. This obviates the need for seed rotation because the thermal condition of the melt can be varied at will. The oxygen content of crystals prepared in this furnace is similar to that found in silicon rods prepared by floating-zone melting in a vacuum or dry hydrogen.

The construction of nuclear fuel elements necessitates the welding of a variety of reactive metals and their alloys, such as zirconium, titanium, molybdenum and beryllium. Welding by electron bombardment heating[2,3] has been found to give a better-quality weld for most metals than welding in an inert gas. P. Thomé (Centre D'Etudes Nucléaires de Saclay, France) described various electron guns in which the electron beam is focused to a target spot ranging in diameter from 0.01 mm.^{2} to 0.3 mm.^{2} for 20 m.amp. and 1 amp. bombarding currents respectively at 20 kV. The beam of electrons passes through a hole in an earthed screen situated close to the components being welded, which are also at earth potential. This reduces the risk of glow discharge and arcing when fusion occurs. A further advantage is that there is no variation in the focus size with different shapes of pieces being welded. With the use of pulse heating, it is possible to apply a very high power to a small area and, if the speed of the work-piece is correctly related to the frequency of beam chopping, the weld consists of a series of overlapping spots. This permits a greater weld penetration and avoids the collapse of the sides of the weld due to metal flow which may happen in continuous welding, and also minimizes the area of recrystallization.

The general impression left by the conference was that in spite of some fundamental disadvantages, heating by electron bombardment will continue to play an important part in the science and technology of the more refractory metals and insulators, and will undoubtedly find other applications in high-temperature researches.

TRANSISTOR CONVENTION AND EXHIBITION

AN International Convention on Transistors and Associated Semiconductor Devices was held at Earls Court, London, during May 21–27. The Convention was organized by the Electronics and Communications Section of the Institution of Electrical Engineers, which also promoted the International Transistor Exhibition held at Earls Court during the same period. The opening lectures were given by Prof. J. Bardeen, Dr. W. H. Brattain and Dr. W. B. Shockley. Some thirty further lectures were distributed among the eleven general and eleven specialist sessions that followed (mostly two at a time in parallel), brief summaries were presented of some eighty original papers, and some thirty-seven further original papers, of which either the full text or a brief digest had been previously circulated to those attending the Convention, were taken as read. The discussions at the sessions were rarely lively, perhaps because of the size and formality of the meetings and the acoustical defects of the halls (it was surprising not to find transistorized roving microphones provided to overcome this difficulty).

In his lecture Shockley considered the factors limiting the capabilities of the 'transistor-diode'—a silicon transistor operated without external base connexion up to voltages at which avalanche multiplication at the collector junction compensates for the initially low injection efficiency of the emitter—as a fast switch for heavy currents. The tendency (due to the transverse ohmic voltage drop in the base region) for part of the emitter junction to draw to itself current from the rest could be overcome by switching on quickly enough after ensuring (by a suitable controlling wave-form) that the whole of the emitter is first just-sufficiently turned off. As an example an oscillogram was shown of a current pulse rising to 50 amp. in 20 mμsec. across a load of about 0.5 ohm. In a separate paper Shockley showed that the minimization of the total capacitance of the emitter junction (also necessary in the device just considered) requires an optimum finite depletion layer thickness, on account of carrier storage in the layer.

Pritchard's lecture brought out the unsatisfactoriness of present commonly used equivalent circuits for transistors, particularly as regards the representation of the base resistance. Linvill generalized the Thevenin and Norton representations of a 2-terminal network to cover 2-ports, including the effects of internal 'contamination' generators representing, for example, noise or the dependence on temperature of d.c. parameters, and showed how the choice of an optimum source impedance could be solved generally for each of the last two situations. J. J. Sparkes showed that for some proportion of transistors the components $C_{b'e}$ and $G_{b'e}$ of the hybrid-pi equivalent circuit depart from their expected dependence on frequency, and suggested that the departures could be accounted for in terms of minority-carrier storage either in the emitter region or laterally in the base region. The effect could be correlated with anomalies in the switching characteristics.

The concept of charge-control (in contrast to current-control as generally considered typical of a transistor and voltage-control of a vacuum tube) was applied in detail by Beaufoy and by Kruithof to the quantitative description of the switching characteristics of transistors, and a generalized justification of the concept was presented in the lecture by Prof. Middlebrook.

Several papers set out to consider costs as related to some of the combinations of technologies now possible in the manufacture of transistors in large quantities. Although full agreement was lacking (not surprisingly, in view of the different markets and different degrees of reliability sought), a consensus of opinion seemed to favour one or other form of 'mesa' geometry, using diffusion alone or together with alloying, as the structure of the future. By the use of 'photo-lithographic' or other masking methods, large numbers of junctions could be completed simultaneously on each wafer of germanium or silicon, leaving a minimum of handling for the mounting and encapsulation of the individual transistors.

Atalla reported experiments on the electrical stability of silicon surfaces on which a thick (300 A. or more) oxide layer had been grown by exposure to water vapour or oxygen at about 1,000° C. Such surfaces showed exceptional freedom from effects usually ascribed to changes in the density or nature of 'slow' electronic trapping states on the outer surface of the oxide; a reversible creep effect observed for a humid ambient in the leakage current of a p–n junction having such a surface treatment was ascribed to the inversion layer induced in the underlying silicon on one side of the junction by the mobile ions electrolytically separated in the adsorbed water film as a result of the bias voltage applied across the junction. The oxide layer itself could withstand some 0.1 V. per angstrom of thickness and should preferably be made thick enough to support the full breakdown voltage of the bulk p–n junction.

The reliability of complete devices was considered explicitly in two papers, one of which showed that the activation energy for the ageing mechanism for a particular type of p–n–p alloyed germanium unit was about 1.2 eV., the end of useful life being brought about by the onset of rapid increase in leakage current and noise in a way characteristic of attack by water on the germanium surface.

A number of papers were devoted to the electrical parameters of semiconductor devices, and to their measurement. The frequency limitation (at about 1,000 Mc./s.) set by the base width of transistors could be avoided by using single junction devices such as the variable-capacitance diode, and the diode proposed by Esaki in which the depletion layer is so thin as to allow tunnel effect to dominate the behaviour at low forward biases. It was necessary in high-frequency measurements to bring the point of measurement as close as possible to the envelope of the device. Measurements in the switching field were dominated by the charge-control approach, which uses rectangular wave-forms and *CR* networks.

Sixty-four papers were devoted to applications; computers and switching applications were much the most prominent. Here the low power consumption and promised high reliability of transistors were seen to be of paramount importance, particularly as the earlier limitations on speed of operation were being largely overcome by developments in high-speed switching transistors. Chaplin illustrated the use of selected high-frequency alloy transistors (having a cut-off frequency of current gain of only about 10 Mc./s.) in the avalanche mode to generate pulses with times of rise of the millimicrosecond order.

Second in prominence to computers was the field of communications; here once again the transistor could reduce the size and power consumption of both mobile and fixed equipment and sometimes obviate the need for buildings. A paper by Grosser on space-division electronic telephone exchanges illustrated the important part that the *pnpn* structure can play as a substitute for a cross-point switch. Cave, Neu and Sim have used some specially made point-contact germanium diodes as variable reactance modulators to control up to several hundred milliwatts of power at millimetre wave-lengths, with switching times as low as 3 mμsec.

Power diodes, silicon four-layer controlled rectifiers, and power transistors were all being applied to power supply and control. Besides emphasizing the small size and high efficiency of these devices, papers directed attention to the protection problems arising from the rapidity with which damage can occur.

In instrumentation, the diverse properties of semiconductors were being applied to a very wide range of applications. There were papers on the design of Hall effect multipliers, and also on single-crystal infra-red detectors using intermetallic compounds. Klein and Straub suggested that fast-neutron dosimetry could be carried out by electrically assessing the damage caused in germanium and silicon, and proposed an assembly of high-resistivity p-type germanium and lithium-6 for thermal-neutron dosimetry. McKenzie and Bromley dealt with the use of gold–germanium junctions as proportional particle spectrometers having a fast rise-time (< 3 mμsec.).

The exhibition was very well staged and paid due attention to research and up-to-date development as well as more conventional technology. The many pieces of equipment using transistors illustrated well their versatility and wide field of application. The exhibition showed also the extent to which industries ancillary to semiconductor technology, producing equipment such as furnaces, radio-frequency heaters, air-conditioning equipment, control instrumentation, etc., and supplies of high-purity material, are springing up. Among the newer semiconductor devices were mesa transistors from the United States and four-layer controlled rectifiers, and among the applications was a high-speed sampling oscilloscope exhibited by the Atomic Energy Research Establishment. The University of Birmingham showed experimental work on space-charge-limited currents in cadmium sulphide crystals. Associated Electrical Industries Research Laboratories showed some of the results of their investigation of etch-pits and other surface defects on germanium and silicon crystals, and of the diffusion of aluminium towards dislocations in silicon crystals.

This Convention was not intended as a continuation of the Reading–Amsterdam–Garmisch–Rochester series sponsored by the International Union of Pure and Applied Physics, but rather as one to bring together the specialists from among the makers and users of transistors. It had something in common with the germanium and silicon materials and devices sessions of last year's Brussels conference. It is, however, to be hoped that the organizers of future conferences on transistors and related devices will take note of the very real risks of devaluation of the meetings caused both by overloading and by dilution of the programme with material that is either not pertinent enough or novel enough to those (generally already more or less expert in the subject-matter) most likely to benefit from the discussions.

NEW MEDICAL-SURGICAL BUILDING OF THE ONTARIO VETERINARY COLLEGE

THE new medical-surgical building of the Ontario Veterinary College was opened recently by two ministers of the Province, the Minister of Agriculture, the Honourable W A Goodfellow, and the Minister of Public Works, the Honourable T R Connell In Canada and the United States there is a division of responsibilities for certain service between the federal and the local government, and in both countries education is a local responsibility and provided by the Province or the State The College was founded in Toronto as a private institute in 1862 by Andrew Smith, a graduate of the Royal Dick Veterinary College in Edinburgh, and was acquired by the Government of Ontario in 1908 It was affiliated to the University of Toronto at that time and was transferred to Guelph in 1922 The present dean, Dr T Lloyd Jones, a Welsh-born Canadian, was appointed in 1952 Dr Jones has done a great deal to improve the teaching and research facilities of the College He is interested in the broad field of veterinary education, has travelled in the United States, South America, India and Europe, to study this subject and has acted as a consultant on international problems in veterinary education

The new buildings provide incomparable facilities for teaching clinical subjects , the older accommodation has also been retained for housing animals for disease investigation, thus greatly increasing the available animal space To provide a similar building in Britain would cost about one million pounds Facilities for teaching the preclinical subjects are provided on the same generous scale, and it is proposed to re-house some of these departments in the next few years Generally, the veterinary schools in North America are on a more lavish scale than those in Britain At Guelph the new accommodation brings the college to a very high level even by American standards There is only one other college in Canada, at St Hyacinthe, Quebec, where instruction is given in French

The College is affiliated to the University of Toronto, but its administration is vested largely in the dean and the Veterinary Faculty, with responsibility to the Ministry of Agriculture Courses of study are submitted to the Senate of the University of Toronto As a result of the growing demand for university education in Canada, the educational institutes at Guelph may, in the not too distant future, attain full university status If this takes place it would be a reversal of the pattern so common in Britain where arts and humanities so often precede the science subjects Guelph would be unique in having veterinary science as its oldest faculty, 1862, followed by agriculture twelve years later This latter has developed into a very large faculty comprising large units for each of its component subjects Guelph and Toronto are about sixty miles apart, but this distance has not prevented close collaboration between members of the medical and veterinary professions in a number of research subjects For many years there has been a close liaison between the Department of Physiology of Toronto Medical School and the Surgery Department of the Veterinary College In the more recent past a joint team of medical and veterinary workers has carried out an investigation on atherosclerosis and studied the effect of certain phospholipids in experimental work on pigs

The new building is constructed in red rustic brick and modern building materials have been utilized in the floors, walls and ceilings, each suitably selected for function but designed in such a way that æsthetics and function combine to form a most attractive building Those who planned the buildings studied the layout of a number of clinical departments They were able to avoid the faults which experience had brought to light in several schools There are several operating theatres equipped for large animals and a number of small animal theatres all serviced by central sterilization The X-ray equipment is specially designed for large animals and has special Buckie screens for use with horses and cattle A large therapy unit is also available Housing has been provided for all types of animals, and the small animal unit is up to the standard of a modern hospital and is air-conditioned throughout

In meeting the cost of this magnificent new building the Provincial Department of Agriculture has recognized the great contribution that can be made and has been made by the veterinary profession on an increasing scale to the economy of the country This type of clinical department is particularly essential in veterinary schools where the teaching material cannot be provided in existing hospitals

Eleventh Annual Convention of the Canadian Veterinary Medical Association

The Convention, held in the Ontario Veterinary College, was attended by more than six hundred veterinarians from Canada, the United States, Great Britain, South America and the Caribbean area The visitors included practitioners, federal and provincial workers, and those interested in research, education and public health Meetings were held in the new hall and in the Agricultural College buildings In a presidential address, Dr J N Henderson, professor of clinics, expressed the view that great changes were taking place in agriculture, that farming was no longer a way of life but was becoming a means of earning a living and that small units would have to merge to form a unit that would give a financial return comparable with other occupations The veterinary profession would have to train graduates who were fully aware of economic factors in animal production and be able to provide an appropriate professional service

There were papers on many aspects of modern surgical techniques in large and small animals and an up-to-date review of the application of radiology to veterinary practice Fundamental aspects of bacteriology and virology were discussed, and papers dealt with the zoonoses with particular reference to government participation in schemes of control The role of the profession in the civil defence programme was outlined The structure of the poultry industry in North America has changed radically during the past ten years and the role of the profession in these new circumstances was discussed While there is a general acceptance that the medical and veterinary professions have a great deal in common in teaching and research, the main divergence arises at the point of application to their respective patients Economic considerations are of greatest influence in the poultry industry, where a setback in rearing birds may represent the difference between a profit and a loss , there are similar considerations with all the farm animals and it is only with pet animals that sentiment replaces economic considerations The diverse problems arising in controlling rabies were discussed and a film was shown of clinical cases of rabies in dogs, cats and cattle In North America there is a reservoir of infection in wild life—foxes wolves, skunks—and relatively few cases in dogs In Trinidad there is a vastly different problem where vampire and other bats act as reservoirs and the epizootic pattern in cattle varies with the disease position in colonies of bats These colonies break up and disperse when furious rabies develops and causes infection in cattle in new areas In Great Britain dogs and cats entering the country are held in quarantine for six months and it is clear that this is a small price to pay for freedom from this disease There were three British veterinarians present who contributed to the proceedings J N Ritchie, chief veterinary officer of Great Britain, presented a paper which surveyed the present position of the veterinary services in Britain, and W L Weipers, of the University of Glasgow, reviewed developments in veterinary education D D Lawson, of the University of Glasgow, presented a paper on thoracic surgery and gave a televised demonstration of volatile anæsthesia in the cow and the dog

This Convention provides a forum for the discussion of scientific and administrative matters which affect the profession in Canada As Guelph is the alma mater of the majority of veterinarians who live in Canada, the meeting in this city also took on the character of an alumnus reunion and the social functions were very well attended

CONTROL OF GOVERNMENT RESEARCH AND DEVELOPMENT EXPENDITURE IN BRITAIN

THE seventh special report from the Select Committee on Estimates for the session 1958–59* contains the observations of the Treasury on the sixth report from the Select Committee for the session 1957–58 dealing with Treasury control of expenditure (see *Nature*, 182, 1467 , 1958) While the Treasury agrees with the Committee's general analysis and many of its comments on particular points, the Treasury suggests that in some respects the Committee's conclusions imply some misconceptions of what is needed, what is possible and what is in fact done It is claimed that the theory of departmental responsibility and partnership has been steadily pursued under successive Governments for about forty years, and the Treasury does not agree that, while new expenditure may be carefully watched continuing expenditure may escape relatively unchallenged Although the main responsibility for vigilant watching for economy in continuing expenditure rests, and must rest, with the spending Department, the Treasury does in fact supplement the Department's own efforts by maintaining a constant watch on continuing expenditure, as well as by bringing particular areas of such expenditure under special review from time to time A high proportion of the Treasury's time is in fact devoted to considering such continuing expenditure

On the Committee's suggestion that eventual commitments are inadequately assessed, the Treasury points out that a wide degree of uncertainty must often remain as to the eventual cost of research policies or major developments involving the solution of scientific and technical research problems , the comment is made that it is unrealistic to suppose that some alteration of financial technique in the Treasury could avoid such difficulties. Secondly, the Treasury points out that forecasts of all civil expenditure, up to three years ahead, have in fact been prepared annually for many years past, and play a very important part in the general control of Government expenditure Without claiming that the technique of 'forward looks' is yet as fully developed or effectively exploited as it might be, the Treasury points out that Ministers are able to decide how far it is necessary to review existing policies reflected in the forecasts, and to adjust new policies which they may have had in mind, to contain the total of Government expenditure within acceptable limits In devoting further attention to this matter, the Treasury undertakes, however, to have full regard to the Committee's comments Again, while the Treasury agrees generally with the Committee as to the importance of prior sanction control, and also that the limits of delegated authority should be periodically reviewed as is at present done, it does not interpret the Committee's report as recommending in general any major change in the existing policy It agrees with the Committee's view that delegation so far as is compatible with the reservation to the Chancellor of the Exchequer of the power to discharge effectively his own essential responsibilities is primarily an attitude of mind which should lead to action whenever opportunity offers , but the three criteria suggested by the Select Committee in this connexion are regarded neither as a complete guide nor, within the ground they cover, as a wholly reliable one

The Select Committee on Estimates had recommended specifically that a small independent committee, which should have access to Cabinet papers, should be appointed to report upon the theory and practice of Treasury control of expenditure This recommendation the Treasury does not accept, and the report sets forth at some length the reasons why the Government is not prepared to accept the recommendation , although in view of the Committee's observations, the Government is initiating an internal inquiry, to be conducted under the general authority of the Chancellor of the Exchequer, into the principles and practice which govern the control by the executive of public expenditure The conclusions reached by the Government will be reported to Parliament in due course

---

* Seventh Special Report from the Select Committee on Estimates, Session 1958–59 Treasury Control of Expenditure (Observations of the Treasury) Pp 16 (London H M Stationery Office, 1959) 1s net

The Treasury recognizes that the operation of Treasury control should be under constant review, but it does not consider that a review by an outside committee would be useful, partly because it would involve, in effect, a review of the Chancellor's conception of his own responsibilities, and partly because it would probably be found that a review of this kind would need to be extended beyond the Treasury itself into Parliamentary practice and into the financial control exercised by each major Department of State The Treasury submits that it would be inappropriate for the Government to seek recommendations on Parliamentary practice from a body independent of Parliament, and that a realistic appraisal of the Government's financial control involves also consideration of the working of the central processes of government It would also be inappropriate, the Treasury believes, for an independent committee to scrutinize and pronounce on the inner counsels of Government or on the resulting decisions, for which the Government is responsible to Parliament alone

Some reservations may be entertained on these points , but so far as the scientist or technologist is concerned, comment may well be left until the committee inquiring into the methods of managing and controlling research and development projects, of which Sir Solly Zuckerman has now succeeded the late Sir Claud Gibb as chairman, reports in due course It should suffice to note meanwhile that the Treasury is very conscious of the need for strengthening and developing on the right lines, the control, whether by the Treasury or by Departments, of expenditure on research and development, and is in broad agreement with the Committee's observations on these matters Discussions of which the subcommittee was informed in evidence have already resulted in agreed arrangements, which it is hoped will prove satisfactory in practice, for the closer association of the Treasury with work on defence research and development programmes

THE U.S. NATIONAL ACADEMY OF SCIENCES—NATIONAL RESEARCH COUNCIL, 1957–58

THE report of the U S National Academy of Sciences—National Research Council for 1957–58 (Washington, D C National Academy of Sciences—National Research Council, 1959), published with the President's review and the report of the Treasurer, covers briefly the work during the year of the eight divisions of the Council, of the United States National Committee for the International Geophysical Year, and of the Office of International Relations and the Office of Scientific Personnel The president, Dr D W Bronk, points out that the operating budget of the Academy is now about 10 6 million dollars, an increase of 3 5 millions on 1956–57, and two-thirds of its direct expenditure came from federal agencies A major undertaking (at the request of the Air Research and Development Command) of the year was a study of the scientific and technological future of the Air Force, while the Council's Highway Research Board is now responsible for conducting the American Association of State Highway Officials Road Test at a cost of more than 20 million dollars The Committee on Meteorology, formed two years ago, has completed its study of how meteorology could be furthered, with reference to the needs of the Weather Bureau, and has proposed the establishment of a National Institute of Atmospheric Research During the year a Committee on Oceanography was organized and the Division of Mathematics, with the assistance of the National Science Foundation, completed its survey of research potential and training in the mathematical sciences At the request of the Secretary of Commerce the Academy is organizing a committee to evaluate the functions and operations of the Department in relation to national needs, with especial reference to the National Bureau of Standards, the Weather Bureau, Patent Office and Office of Technical Services

Among miscellaneous activities of the Council not assigned to a division, the report notes those of the Advisory Board on Education, which has given special attention to improving the education of teachers and to studies of science curricula and courses, the committees concerned with the study of the biological effects of atomic radiation, the establishment in February 1958 of a Committee on Polar Research and the work of the Space Science Board, which held its first meeting in June 1958, and is studying the opportunities for scientific research opened up by the advent of modern satellites and rocket tools and their needs

To a certain extent, some of the activities described in this report, such as those of the United States National Committee for the International Geophysical Year and the Office of Scientific Personnel, are covered by the annual report of the National Science Foundation, from which they received financial support and need not here be further described Of those of the Research Council's own eight divisions a few examples are selected for illustration The Division of Anthropology and Psychology participated in some cross-disciplinary projects including a contract with the Air Force for a study of problems connected with bio-astronautics, under the supervision of the Division of Medical Sciences, and a conference on Psychological Research in Education It is also administratively responsible for the Armed Forces–National Research Council Committee on Vision The Division of Biology and Agriculture reports no new major projects The Division of Chemistry and Chemical Technology at its annual meeting was concerned with international chemical affairs and the improvement of documentation in chemical literature but reports no outstanding activities of its units

The Division of Earth Sciences rendered advisory services to the Federal Government through its committees and also conducted the Arctic Sea Ice Conference in February 1958 at the request of the Government. The Division of Engineering and Industrial Research provided advisory services over a wide field of increasing importance and complexities, including such matters as electrical insulation, fire research, highway research, building research, prosthetics research. The Division of Mathematics appointed two new committees, one on statistics and the other to report both to the Division and to the Advisory Board on Education, on mathematical films and television. The Division of Medical Sciences initiated a new project in medical genetics, which will establish a large roster of veteran twins, diagnosed as to zygosity, as well as other studies of rheumatoid arthritis, lesions of the lumbar disk and Japanese *B* encephalitis. The interest of the Sub-committee on Trauma continued to centre on the treatment of burns particularly those involving the respiratory tract. The Division also participated in the establishment of the Inter-departmental Committee on Blood Programme Research and through its Committee on Sanitary Engineering and Environment the Division is increasingly concerned with toxicological hazards arising from the rapid introduction of many new types of material into industry and into the home. The Committee on Tissue Transplantation sponsored a symposium on serological immaturity and agammaglobulinæmia and non-specific forms of lowered resistance to transplanted tissues, including the effects of radiation and cortisone. A primary aim of a revised programme of the Committee for Research into the Problems of Sex is the encouragement of young investigators interested in careers in the field of behavioural research.

The Division of Physical Sciences reports a balance between activities in response to requests from the scientific community and in response to Government requests and between those in physical science and in applied science. Its Committee on Nuclear Science continued to be the largest and most active. Its services to the Government included those of the Committee on Undersea Warfare and the Mine Advisory Committee, and the critical review of Air Force research and development planning noted above and a review of the activities of the National Bureau of Standards.

CLERICAL SALARIES IN BRITAIN

THE eighth of the Office Management Association's surveys of clerical salaries embraced a sample of almost ninety thousand clerks[*]. For the most part, these were employed in private commercial, industrial and professional offices. In addition, one part of the survey related to clerks employed in the public service, nationalized industries, and the joint stock banks. In one form or the other, therefore, the survey supplied information about the salaries of clerks in all parts of the British economy.

Women clerks formed 64 per cent of the clerks in the sample. This compares with the 67 per cent of women among the clerks employed in the corresponding industries in 1951 when the last census of population was taken.

The clerks were employed in a wide variety of British industries but some industries were better represented in the sample than others. ceramics, glass and cement, etc.; chemicals and allied trades; metal manufacture; engineering, shipbuilding, and electrical goods; textiles; food, drink and tobacco; other manufacturing industries were well represented by samples amounting to 10 per cent or more of the clerks employed in industry. The very large number of clerks employed in vehicle manufacture, distributive trades, and in professional and miscellaneous services, were represented by samples of less than 5 per cent. There had been no change since earlier surveys in the proportion of clerks employed on work of this kind. For the men this proportion was only 60 per cent; but 83 per cent of the women were in routine jobs.

On the whole, male clerks' salaries have risen between 12 and 16 per cent in the past two years and those of women clerks between 11 and 13 per cent. The exceptions to this pattern are male clerks doing the lowest grades of routine jobs, whose salaries have risen by between 16 and 27 per cent and the women doing the lowest grade of routine jobs, whose salaries have risen by 14 per cent (clerks under twenty years) and 17 per cent (clerks over twenty years). As the index number of retail prices has risen by 7 per cent during the same period, the real salaries of the clerks have gone up between nearly 5–9 per cent for men and 4–6 per cent for women. Superimposed on this general increase is a large rise for clerks doing the lowest routine jobs.

Manual workers' wage rates during the period from February 28, 1956, to the same date in 1958 rose by just over 11 per cent. Clerical salaries, therefore, rose as much as, or more than, the wage rates of manual workers during the past two years. Wage rates do not, however, tell the whole story concerning manual workers' share of the national economic cake; the fluctuations in their earnings may differ quite considerably from the fluctuations in wage rates. No similar complication affects clerical salaries to anything like the same extent.

It appears, nevertheless, that clerks have in this period done rather better than manual workers in the continuous process of redistributing income. This comes after a decade in which male clerks have been losing ground to manual workers.

Increases have been proportionately less for clerks engaged on more senior and responsible work. Many have scarcely had any increase in salaries at all over and above that accounted for by the fall in the value of money. Because the salary increases during the past two years have been proportionately slightly less for women than for men, the gap between the salaries of men and women clerks doing similar work has widened a little since 1956.

The United Kingdom does not form a single market for clerical labour and even nation-wide employers of clerks recognize this, at least to the extent of introducing London allowances into their national scale. These scales and allowances may be administratively convenient, but the pattern of local clerical markets is more complex than the simple one of a London market and a provincial market assumed by most national employers. The areas of the highest salaries were mainly those having the prosperous engineering, shipbuilding, food-processing and chemical industries in good measure with a high proportion of export trade. It is reasonable to assume that the pattern of clerical salaries for adult male clerks followed a pattern of economic prosperity.

---

[*] Clerical Salaries Analysis, 1958. (Office Management Association, 58 Victoria Street, London, S.W.1.) 42*s*.

London comes fairly low down on the scale. Within Greater London there was only one district—the West End—where salaries were comparable with those on Merseyside. This is in contrast with the usual assumption that salaries are generally higher in London than in the rest of the country.

The pattern of variations of salaries for women clerks is simpler and more in accordance with traditional ideas. Greater London was the area of high salaries; the other conurbations had noticeably lower salaries with little to choose between them in contrast with the experience of men clerks in this area.

HELP FOR THE ARTS

ALTHOUGH the full policy of the Calouste Gulbenkian Foundation of Lisbon includes the fields of science, art, education and charity, it now announces that it is prepared to implement the suggestions in a report just issued[*]. This means that for the next three or four years the emphasis of the activities of the Foundation in the United Kingdom will be almost exclusively in the field of the arts.

The report, prepared by a small informal committee consisting of Lord Bridges (chairman), the Countess of Albemarle, Mr. Noel Annan and Sir George Barnes, is the result of their deliberations to help the Foundation by a review of the needs of the arts in Britain. After a few discussions in London the committee visited Bristol, Cardiff, Glasgow, Liverpool, Newcastle upon Tyne and Nottingham. Information was also supplied by a hundred local authorities and by all the universities.

Probably the most striking and indeed definite conclusion is that the arts need help in the provinces to a far greater extent than they do in London. Another point is that far greater support is needed for the arts than in the past and also that this is not a temporary need. This means that in the future public authorities will have to find more money for the arts. It is also stressed that far more needs to be done to-day to render the arts accessible, that there should be more scope for experiment in order to invigorate the arts and that more should be done to foster appreciation among the young. If, as the committee believes, the Foundation can do its best service by stimulating art in the provinces it is pointed out that although under the Local Government Act of 1948 local authorities are permitted to spend up to a 6*d.* rate each year on any form of entertainment it is ascertained that over the whole country expenditure does not exceed ¾*d.* rate for museums and art galleries and ⅕*d.* for music and drama. The members of this informal committee consider that the universities could and should do much more for the 'practice' and encouragement of the arts. Traditionally, this has been left to university societies and thus is outside the scope of the university patronage.

In discussing the specific ways in which the Foundation can help, it is stressed that it should be prepared to back individuals—and to encourage and foster new developments or growing points, feeling that eventually they will be self-supporting and attract permanent support from public funds or elsewhere.

Museums and art galleries receive much consideration, and although the committee welcomes the increase in grants recently announced it is suggested that pictures accepted by the Treasury in lieu of death duties should in certain cases pass to the provincial galleries. This involves the acceptance of pictures perhaps not of exceptional importance but of great interest to a local gallery. It is also felt that although museums have done much good work in developing school services they seem to have lagged behind the expansion in other educational fields. A more active policy of loans between museums is advocated, and for this a general survey of material in the collections is essential. This also leads to the establishment of an improved conservation service. It is also suggested that the Foundation might help to buy works of art for provincial galleries.

In conclusion, the committee considers that Great Britain is producing artists of the highest quality, but adequate support or patronage is lacking. It is to be hoped that the Foundation gives a speedy implementation to the suggestions in this report and then in good time turns to the support of the sciences in Great Britain.

DIETARY FACTORS IN THE HOMOGRAFT REACTION

By Dr. A. S. PARKES, F.R.S.

Division of Experimental Biology, National Institute for Medical Research, Mill Hill, London, N.W.7

EXPERIMENTS carried out in 1955 with five strains of mice maintained at this Institute showed that ovarian autografts established themselves regularly and became endocrinologically active within an average time of 10–11 days. In three of the strains intra-strain homografts behaved similarly during the four-week period of observation. In the other two strains, intra-strain ovarian homografts took and survived less well than autografts. Inter-strain ovarian grafts took moderately in some combinations, but rarely survived for four weeks[1].

Repetition of some of these experiments two years later showed that there had been a marked increase in resistance to intra-strain grafts. In the three strains re-investigated (*TO*, *PA* and *WT*) 25/27 of such grafts had taken in 1955, and 19 had survived in a functional state for four weeks, whereas in 1957, 15/29 took and 7/29 survived the test period. Various other experiments with gonad grafts in mice and rats made at the Institute about this time also suggested that there had been an increase in homograft reaction.

Review of the animal husbandry showed only one factor of likely significance: the staple cubed diet (diet 41) had been modified by the substitution of vitamin concentrate and molasses for cod liver oil (diet 41*B*)[2], and an investigation was therefore started to find out whether such a change could have affected the homograft reaction.

The technique was as described previously[1]. Young adult females were spayed, the ovarian capsule, the Fallopian tube and the top of the uterus all being removed to minimize the possibility of ovarian regeneration. The ovaries from donor animals were dissected free of adnexa, cut into two pieces and implanted under the skin of the flank. The establishment of an active graft and its survival time were determined by the re-occurrence of cornified cells in the vaginal smear.

The first experiment was to make a new batch of diet 41, so that a direct comparison could be made between mice maintained on it and on diet 41*B*. For this purpose, *PDE* mice, a sub-strain of *PA* mice, were used; these were known to show a vigorous intra-strain homograft reaction (10/30 grafts established and 3/30 surviving 4 weeks). *PDE* breeding mice were maintained on diet 41 for some months and then the intra-colony homograft reaction in 40 females drawn from this colony was compared with that in 40 females of the same strain maintained on diet 41*B*. The results are shown in Table 1.

Table 1. THE INTRA-STRAIN HOMOGRAFT IN COLONIES OF *PDE* MICE MAINTAINED ON DIET 41 AND ON DIET 41*B*

Diet	No. of females receiving implants	No. of females developing active grafts	No. of females with active grafts at 28 days
41	40	28	13
41*B*	40	13	4

The difference in the number of mice developing active grafts was significant at the $P = 0·01$ level and substantiated the idea that the change in homograft reaction between 1955 and 1957 had been associated with the change of diet. The results of a small series of inter-colony grafts were concordant with the presumption that the difference in homograft reaction originated in the recipient rather than in the tissue grafted.

Attention was then turned to the nature of the dietary factor involved in modifying the homograft reaction. Diet 41 had been abandoned because of the destructive action of the cod liver oil on the vitamin E. It was thought, therefore, that treatment of 41*B* with excess of cod liver oil might abolish its effect in augmenting the homograft reaction. Results with 20 mice, however, gave no support to this idea; but the result cannot be regarded as conclusive, because the unpalatability of the treated diet 41*B* prevented an adequate preparation period.

At this stage, my colleague Dr. J. H. Humphrey directed my attention to the work of Axelrod and others, who had investigated the effect of various dietary factors on immunological response and who had found that pyridoxine-deficiency, whether induced by deficient diets or pyridoxine antagonists, notably depressed antibody formation[3,4].

On the basis of these reports plans were made to test the homograft reaction in pyridoxine-deficient animals. In a first experiment, 10 *PDE* mice maintained on diet 41*B* were injected daily with 0·25 ml. saline and a similar group with 0·25 ml. saline containing 2·5 mgm. deoxypyridoxine. After four weeks, intra-group ovarian homografts were made, treatment being continued. After another four weeks, 5 of the 9 surviving antagonist-treated animals retained active grafts, but only one of the 10 control mice. This result, although not itself of great statistical significance, was distinctly encouraging and more extensive experiments were carried out on mice receiving homografts after preparatory treatment for four weeks with deoxypyridoxine added to the drinking water in amounts calculated to give an intake of 2·5 mgm. or 5·0 mgm. per day. Results are summarized in Table 2, and indicate that the oral administration of deoxypyridoxine to the recipient markedly increased the survival-rate of ovarian homografts. 5 mgm. daily was not detectably more effective than 2·5 mgm., and was appreciably more toxic in that 7/30 of the animals died during the experiment. The effect on the survival of homografts was abolished by the administration of pyridoxine during the second half of the preparatory period and was therefore due to pyridoxine-deficiency rather than to some side-effect of the antagonist. When re-examined after 3 months, 10/36 of the mice treated with deoxypyridoxine only retained active grafts compared with 0/37 in those receiving deoxypyridoxine plus pyridoxine.

Table 2. TAKES AND SURVIVAL OF INTRA-STRAIN HOMOGRAFTS IN *PDE* MICE MAINTAINED ON DIFT 41*B* WITH AND WITHOUT DEOXYPYRIDOXINE

Preparatory treatment for 4 weeks	Proportion of animals developing active grafts	Proportion of animals with active grafts at 28 days
None	10/30	5/30
2·5 mgm. per day deoxypyridoxine	17/20	12/20
5·0 mgm. per day deoxypyridoxine	19/23	14/23
2·5 mgm. per day deoxypyridoxine	26/38	17/38
2·5 mgm. per day deoxypyridoxine + 1 mgm. pyridoxine per day for last 2 weeks	13/38	2/38

Experiments were then extended to inter-strain homografts, *TO* females receiving ovarian implants from *PA* females. The results are shown in Table 3.

Pyridoxine deficiency is therefore almost as effective in preserving inter-strain as intra-strain homografts, and as with the intra-strain grafts the higher dose did not appear to be more effective. Re-examination of four groups of the treated animals at the end of three months showed that 9/30 retained active grafts.

Table 3. TAKES AND SURVIVAL OF INTER-STRAIN HOMOGRAFTS IN RECIPIENTS WITH AND WITHOUT DEOXYPYRIDOXINE

Preparatory treatment for 4 weeks	Proportion of animals developing active grafts	Proportion of animals with active grafts at 28 days
None	4/20	0/20
2·5 mgm. deoxypyridoxine per day	18/28	12/28
5·0 mgm. deoxypyridoxine per day	9/15	5/15

Table 4. SURVIVAL OF RAT OVARIAN TISSUE GRAFTED INTO PYRIDOXINE-DEFICIENT MICE

Preparatory treatment for 4 weeks	Strain of mouse	Proportion of animals developing active grafts	Proportion of animals with active grafts at 28 days
None	*PA*	11/40	0/40
2·5 mgm. deoxypyridoxine per day	*PA*	10/37	6/37
None	*PDE*	9/19	0/19
2·5 mgm. deoxypridoxine per day	*PDE*	28/40	12/40

Striking results were obtained with heterografts of rat ovaries made into treated mice (Table 4).

In the third group of mice the surviving grafts were removed by operation after five weeks and were found to be relatively very large and, although heavily infiltrated with leucocytes, were found on histological examination to possess numerous follicles and corpora lutea. In general, these heterografts were very different from the few small degenerate specimens which can be found in untreated mice at five weeks after the subcutaneous implantation of rat ovarian tissue.

The effect of pyridoxine deficiency in depressing the reaction against ovarian homografts is greater than that of a single dose of whole-body irradiation in mice[5] and of the same order as that which can be obtained in rats by pre-conditioning the prospective recipient with suspensions of homologous tissue[6]. It is less permanent according to present experience than the effect which can be obtained by the induction of tolerance early in life[7].

While these experiments were in progress, Axelrod and his collaborators[8], in continuation of their earlier work, published the results of experiments on intra-strain skin grafting in pyridoxine-deficient rats. In two strains of rats they found that the percentage of takes in deficient rats was far higher than in normal ones, and in one strain survival at 10 weeks was also far better. Experiments on man, however, failed to give analogous results, possibly because the degree of pyridoxine-deficiency was inadequate[9].

So far as rats and mice are concerned, however, it seems clear that the reaction against skin and ovarian homografts respectively is much reduced by pyridoxine deficiency. According to Axelrod *et al.*[8], "it is possible that this effect is related to an inhibition of the immune response to the antigens of the donor skin in this deficiency state". With this suggestion, it seems desirable to postpone discussion until more facts are available.

My thanks are due to Dr. J. H. Humphrey, Dr. H. R. V. Arnstein and Miss H. M. Bruce for advice, and to Miss M. P. G. Moylan and Miss B. M. Flannelly for technical assistance.

DIAPHRAGMS FOR ANALYSING THE DEVELOPMENT OF CONNECTIVE TISSUE

By PROF. HANS SELYE
Institut de Médecine et de Chirurgie expérimentales, Université de Montréal

TO gain fundamental information about the nature of any complex biological structure or process, we have to develop techniques which permit us to analyse it by breaking it down into its constituent elementary units ; the dissection of organs, the preparation of pure microbial or tissue cultures are examples in point. The study of the laws that govern the developmental mechanics of connective tissue (for example, during normal growth, wound healing and inflammation) has been greatly handicapped by the lack of techniques suitable for an analysis of this kind. Normally, the cells and intercellular structures of connective tissue form an extremely complex maze. Even the simplest linear wound elicits a multitude of interdependent regenerative processes the elements of which (exudate, fibrin, fibres, cells, vessels) interlace in all directions, so that a study even remotely resembling an 'elementary analysis' of the constituents becomes virtually impossible. Accordingly, the scope of the conventional techniques for the study of connective tissue is necessarily limited to the description of histological or chemical components, the uptake of vital dyes, the speed of cicatrization, the measurement of tensile strength, etc.

The object of this communication is to describe the design of diaphragms which, when introduced into connective tissue, present it with simple problems of organization, in that they block growth except along one, or more, regular, predetermined channels. Thus we can obtain single beams of connective tissue, or cords intersecting at any desired angle ; these, like the parallel beams of light produced by optical diaphragms, lend themselves to reveal the underlying order in an otherwise confusing complexity.

All experiments were performed on female Sprague–Dawley rats, with an initial body-weight of 100–150 gm. The sterilized diaphragms were introduced beneath the shaved dorsal skin, under ether anæsthesia. Groups of rats were then killed at weekly intervals, to examine the progress of organization macro- and microscopically.

Analyser diaphragms may be prepared of various materials (plastics, china, rubber, paraffin-coated paper, etc.), but glass is the most satisfactory : it can easily be shaped, chemically cleaned and sterilized, its hard, smooth surface prevents adhesion of tissue to the wall, and its transparency facilitates examination of the contents.

Fig. 1 illustrates a few of the basic patterns of tissue-diaphragms that were employed for analysis.

The simple tube, open at both ends (Fig. 1*A*, *B*, *C*), permits only unidirectional growth, in the form of a

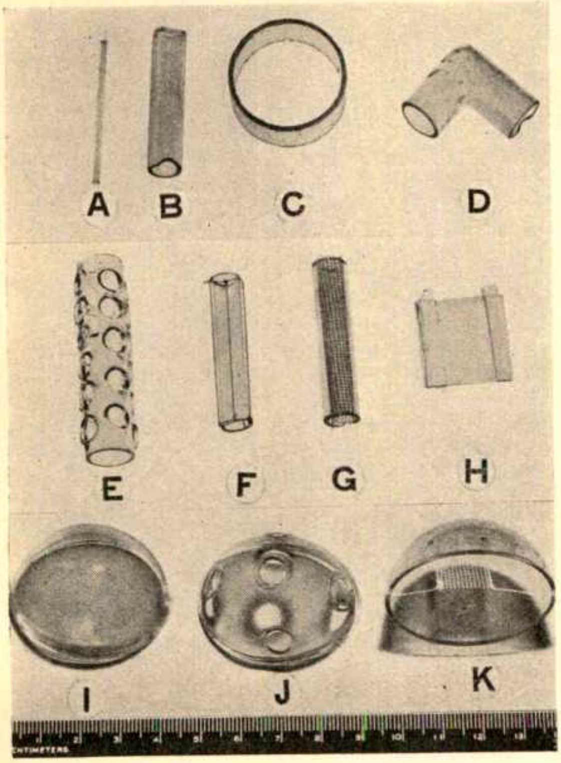

Fig. 1. Samples of various tissue diaphragms

connective-tissue cord that connects the two orifices. The length and calibre of the tube vary in accordance with the problems to be studied; capillaries and small-bore tubes have the additional advantage of being readily implantable, not only into loose connective tissue, but also into muscles, pleura, peritoneum and various parenchymatous organs. Tubes with one end closed revealed that a minimum of two 'tissue bridgeheads' is necessary for rapid organization of a gap, while L-shaped (Fig. 1*D*) and branching tubes (in the form of a Y, T or +) are employed to examine the formation of anastomosing tissue cords at predetermined angles. One perforation or more in the wall of the tube (Fig. 1*E*) offers additional possibilities for the establishment of tissue connexions within a single cylinder (that is, unguided by restraining individual tubular walls around each tissue-cord). Simple, straight tubes, open at both ends, containing a central nylon thread (Fig. 1*F*), an inner parietal lining of fine nylon trellis (Fig. 1*G*), or a central flat 'ladder' of nylon trellis that connects the two open ends revealed that this additional internal scaffolding is especially effective in accelerating organization along the threads. Organization is also expedited by enveloping the diaphragms in nylon trellis; the rapid invasion of the latter by connective tissue furnishes a stabilizing capsule for the whole object. Double plates (two cover-glasses, their surfaces slightly separated by lateral glass ledges) offer the possibility of studying two-dimensional invasion of a flat space (Fig. 1*H*); the tissue formed in this can then be examined by merely placing the entire object under the microscope. Hemispheres, or—because of the shape of the rat's back—hemi-ellipsoids are used to examine factors which influence the three-dimensional organization of rounded cavities. These structures offer no entry to tissue, except at their base (Fig. 1*I*), or have one additional opening or more on the roof (Fig. 1*J*) for the exploration of simple or complex tissue-bridge formation. Finally, minute perforations in the roof (which can afterwards be sealed with a drop of paraffin) make it possible to attach threads or trellises of nylon at any point of the roof, thus connecting it with the base (Fig. 1*K*). It is then possible to explore the effectiveness of the nylon scaffolds as tissue guides.

Fig. 2 shows a hemispherical analysing diaphragm with multiple perforations, under the shaved dorsal skin of a rat, two weeks after implantation. The scar of the incision, through which the object had been introduced (dark spots near the root of the tail), is almost healed; it did not interfere with organization within the diaphragm, because the latter was pushed forward at some distance from the wound to prevent the development of external adhesions and diminish the probability of infection. Owing to the absorption of air from the cavity of the hemisphere, the skin over the perforations is slightly depressed. The depth of these depressions remains limited, however, because, soon after implantation, exudation begins and a characteristic, citrine, thick fluid fills out the empty space. This fluid does not coagulate *in situ*, but has some tendency to do so after evacuation. Eventually, fibrin threads, covered and invaded by histiocytes, connect the parietal openings with the base and thus provide temporary bridges. These are later organized by connective tissue and invaded by blood vessels.

This organization is most clearly illustrated by the simple, unidirectional growth that occurs in straight glass tubes (Fig. 3).

Two weeks after implantation of such a tube (3 cm. long, 0·8 mm. wide, and enveloped in a nylon trellis for better fixation), a straight axial cord has developed between the two openings (Fig. 3*A*). This cord consists of a broad, central spindle made up of fibrin threads and histiocytes. It is attached to the centre of the end-plates by a narrow filament of connective tissue, Van Gieson-positive and well vascularized. By this time, such tubes are completely or almost completely filled with citrine fluid

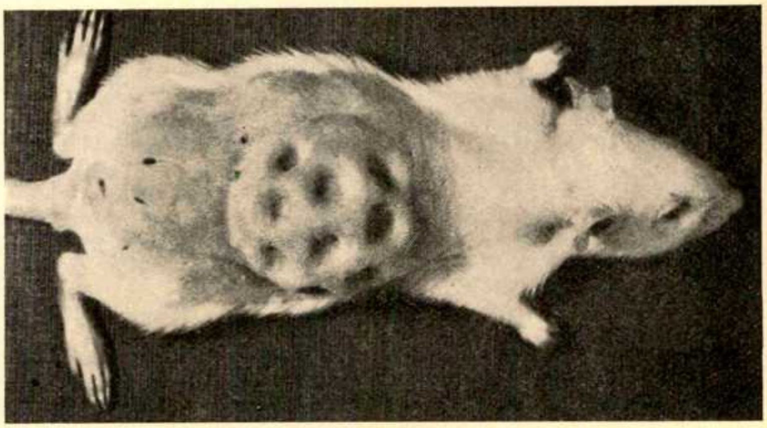

Fig. 2. Hemispherical tissue diaphragm as it appears *in situ*

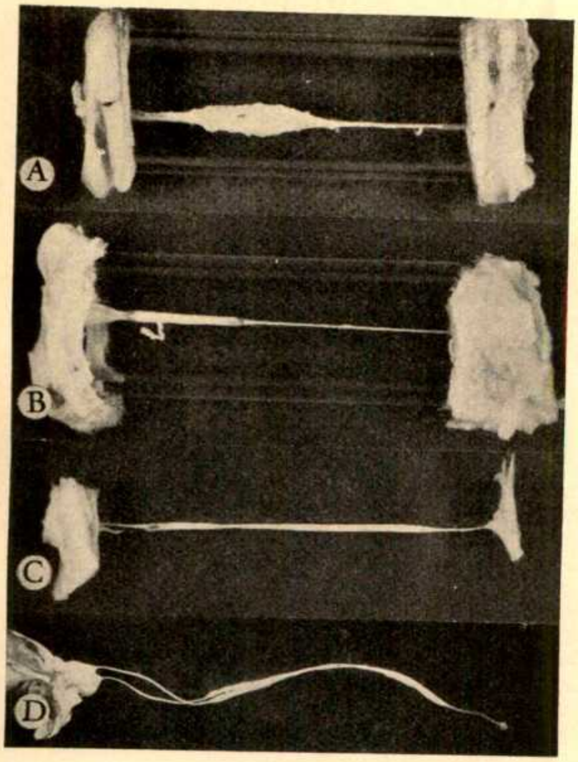

Fig. 3. Various stages and types of axial-cord formation within simple glass tubes. In *A* and *B* the tube and the disk-like connective-tissue plates at the opening are intact; in *C* and *D* the contents are represented after removal from the tube

and, although the two end-plates of connective tissue are broad, the bridge is invariably narrow and attached centrally.

After one month, the fibrin spindle becomes narrower and shorter (Fig. 3*B*); the 'growth line' that separates the light fibrinous centre from the darker invading tissue is reddish in the living animal. Quite commonly, invasion by connective tissue progresses much more rapidly on one side (in Fig. 3*B* on the right) than on the other, but the development of fibrin threads between the spindle and the glass wall (which apparently occurred here because of a rough dirt speck on the wall) is exceptional. It is also quite uncommon to find an accessory, abortive, second cord, attached unilaterally (Fig. 3*C*), or a complete Y-shaped, split cord, in simple straight tubes (Fig. 3*D*). Curiously, within the limits which have been studied so far, the speed with which the two openings are connected by an axial cord, and the thickness of these bridges, are largely independent of the length and width of the glass tubes.

The details of these investigations will be described elsewhere. Here, attention is directed merely to the possibility of analysing the mechanics of tissue growth by the selective restriction of proliferation to certain channels. It is hoped that such analysing diaphragms may prove useful in the study of developmental mechanisms under normal conditions and after the topical or systemic application of growth-modifying stimuli.

These experiments were performed with the aid of grants from the National Cancer Institute of Canada (grant No. 22) and from the Gustavus and Louise Pfeiffer Research Foundation.

ESTABLISHMENT OF PARENCHYMATOUS SPLENO-PULMONARY VENOUS ANASTOMOSIS

By Drs. GEORGE R. WALKER, PAUL FIELD and PATRICK E. CONEN

Research Institute, Hospital for Sick Children, Toronto

A SUCCESSFUL shunt between the splenic vein and the pulmonary venous system via a parenchymatous anastomosis in the dog has been achieved. The investigation was conducted in an attempt to find a solution to the problem of extrahepatic obstruction of the portal venous system in young children. At present, this condition in children is not as amenable to successful treatment by current methods of shunt operation as in adults. Further work will be necessary before application of this experimental work to clinical problems can be undertaken.

Dogs 8–20 kgm. in weight were used. General anæsthesia was induced and continued with thiopentone and succinylcholine chloride in divided doses, respiration being maintained by manual control of flow of oxygen through an endotracheal tube. Tetracycline was administered by mouth for ten days, beginning the day before operation, to avoid the high incidence of acute empyema which occurred post-operatively in the early attempts.

A thoraco-abdominal incision was made in the line of the eighth rib on the left side, and the spleen delivered through the wound. A bulldog clamp was temporarily applied to the splenic pedicle. Most of the spleen was removed, leaving part of the lower pole, measuring approximately 3 × 2 × 1 cm. at the site of entry of the main lower division of the splenic vessels. The splenic capsule was removed except that on the hilar surface.

Next, a Satinsky vascular clamp was placed across the lower part of the lower lobe of the left lung, to act both as a retractor and as a hæmostat. An incision about 3 cm. long was made in the lung on either the costal or diaphragmatic surface, and continued deep into its substance. After bringing the splenic pedicle up through the tendinous part of the diaphragm, the remnant of the spleen was inserted into the opening in the lung and the lung sewn over it.

All clamps were removed and an intercostal drain inserted and connected to an underwater seal. The wound was closed in layers.

The operation is relatively easy to perform, and the procedure is usually completed in 1–2 hr. The overall operative and post-operative mortality was

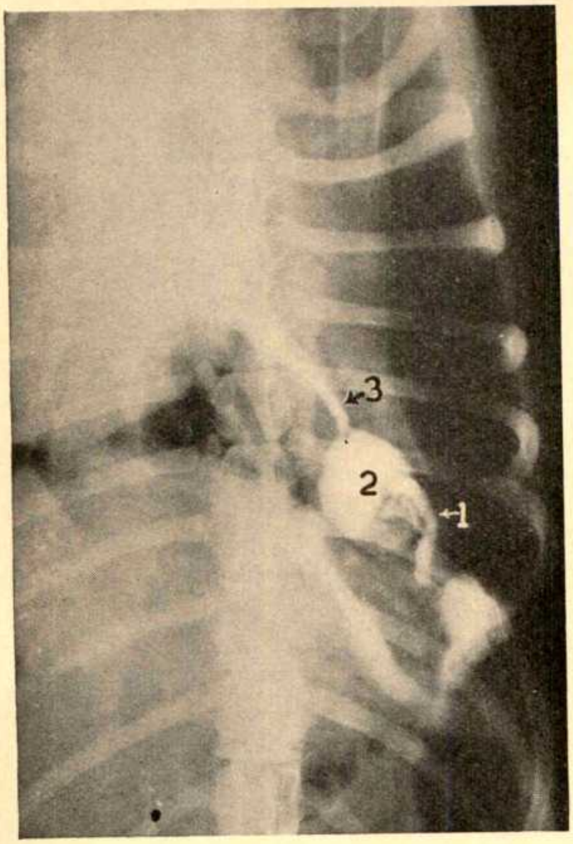

Fig. 1. Venogram showing anastomosis during injection of 'Hypaque –*R*'. 1, Splenic vein; 2, spleen; 3, inferior pulmonary vein

approximately 10 per cent. In the majority of cases, the dogs made rapid recovery and resumed normal activity and appetite within one or two days.

Demonstration of the Anastomosis

Each dog was explored through the original incision 8–10 weeks following the procedure, and the area of anastomosis was examined. It was noted at operation that good pulsation was present in the splenic artery. Most of the left lung was expanding normally, and only a small part of the lower lobe, approximately equivalent to one broncho-pulmonary segment, was firm and thickened.

Demonstration of the anastomosis was made by the following three methods:

(1) *Venography*. The splenic artery and vein were ligated and cut inside the abdomen and a polyethylene catheter was tied into the lienal side of the cut splenic vein. A roentgenogram of the lung was taken during injection of 10 ml. of 50 per cent 'Hypaque' solution.

Fig. 1 illustrates the typical appearance of the roentgenograms in the cases investigated in this way. The dye passed through the splenic vein in a retrograde direction into the implanted spleen and thence via the parenchymatous anastomosis into one of the left pulmonary veins.

(2) *Plastic Preparation*. After excision of the anastomotic area, polyethylene catheters were tied into the left inferior pulmonary vein and into the splenic vein. Simultaneously, liquid neoprene plastic was injected into both catheters at a pressure of 100 mm. mercury, a dark colour into the pulmonary vein and a light colour into the splenic vein. The catheter in the pulmonary vein was removed before that in the splenic vein. The specimen was then

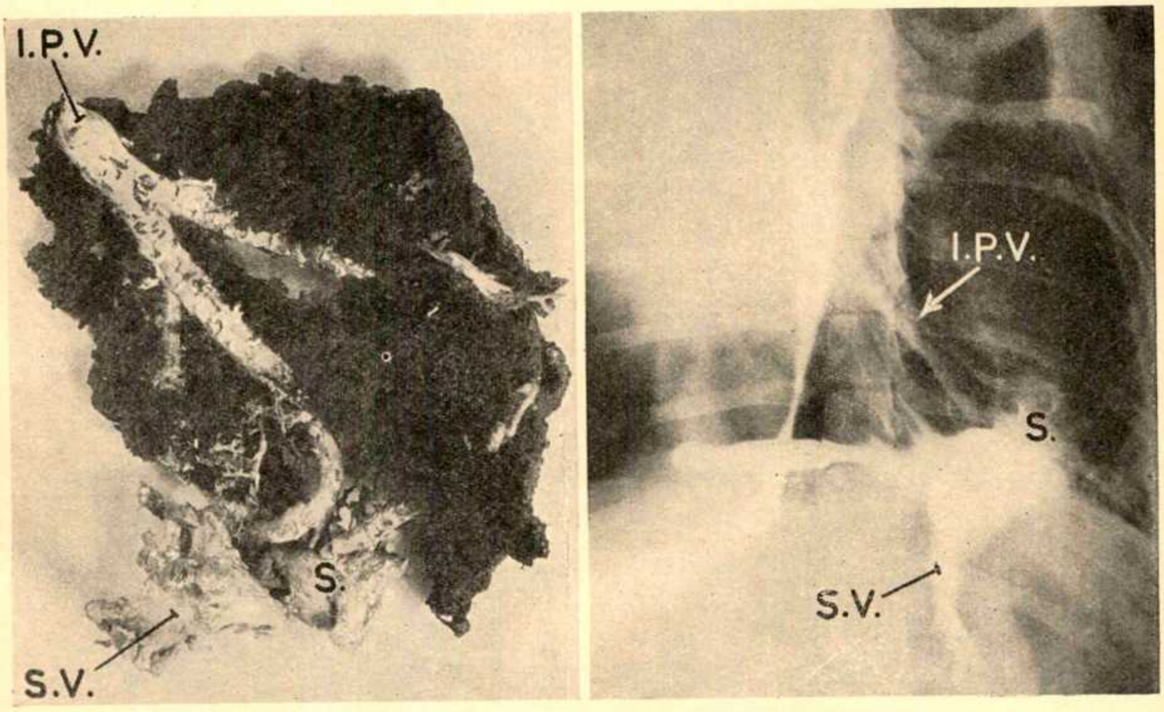

Fig. 2. Plastic cast showing filling of spleen and inferior pulmonary vein following injection into splenic vein. The venogram of the same animal taken during life is also shown for comparison (right). *S.V.*, splenic vein; *S*, spleen embedded in lung; *I.P.V.*, inferior pulmonary vein

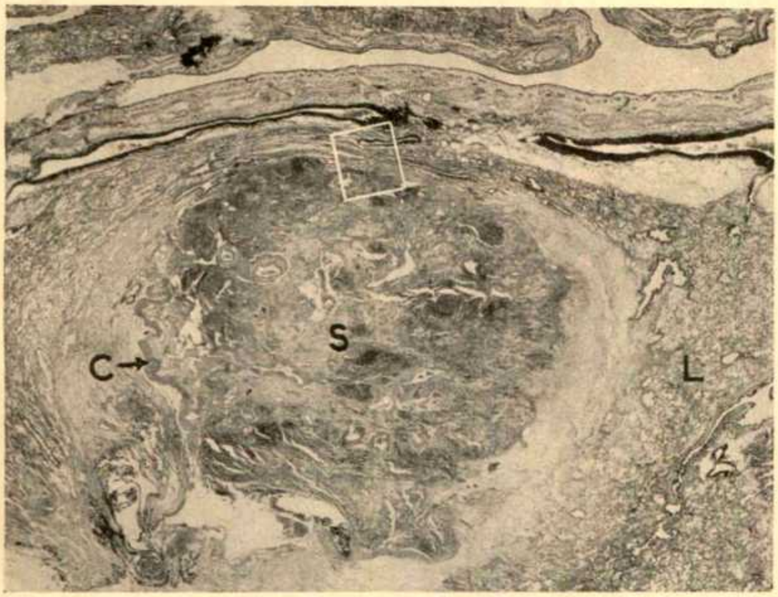

Fig. 3. Low-power view (× c. 6·7) showing the embedded spleen (*S*) and the remnant splenic capsule (*C*) completely surrounded by lung (*L*). (Verhoeff's elastic tissue stain)

immersed in an acid bath which digested the soft tissue and left the solidified neoprene.

Fig. 2 shows filling of the splenic vein, the splenic remnant and the left inferior pulmonary vein with light-coloured plastic. This is in contrast to the dark-coloured neoprene in the small vessels of the lung parenchyma. Fine dissection of the plastic cast showed both colours in all the small vessels of the substance of the lung close to the embedded spleen.

(3) *Histology*. A specimen of lung containing embedded spleen was cut into thin slices and fixed in formalin. Blocks were sectioned serially and stained both by hæmotoxylin and eosin, and also by Verhoeff's elastic tissue and Van Gieson stain.

Fig. 3 shows a cross-section of the embedded spleen in the lung. A small portion of the intact splenic capsule remains while the rest of the spleen merges with the surrounding lung parenchyma. There is increased vascularity in the spleen and a dilatation of the pulmonary vessels surrounding the spleen. Large numbers of vessels are observed just outside the spleen, and dilated vessels are also present in the substance of the spleen (Fig. 4). In some areas a direct connexion between the pulmonary and splenic vessels was demonstrated by serial sections, although no indication of the direction of flow of the blood in the living animal was obtained.

Results and Discussion

In eighteen normal dogs, the spleen was embedded in the lung. Nine of these were examined by methods described above, and in all these evidence was found which was consistent with the establishment of vascular connexions between the two tissues. Of the remainder, five dogs are alive and well, two were operative deaths, and two died of distemper.

In this series of normal dogs a parenchymatous anastomosis between the spleen and the lung has been achieved. The difficulties of producing more than transient portal hypertension in dogs have long been realized, and have been described by Morris[1] as well as others. It was felt that for purposes of this initial study, the existence of portal hypertension in the experimental preparation was not obligatory since if good anastomosis could be obtained in an otherwise normal dog, an even better anastomosis could be anticipated in the presence of portal hypertension.

Further work is being conducted in order to discover the capacity of the anastomosis to dilate and provide a by-pass for an occluded portal vein. Due to technical difficulties, it has not been practicable to measure blood flow through the shunt. It is intended to obtain an approximate estimate of this flow by the use of cine-angiography and by dye-dilution curves. The ability of the shunt to dilate in order to accommodate the increased flow of blood due to portal hypertension is being investigated by performing spleno-pulmonary anastomosis on dogs in which portal hypertension has previously been induced by the method of Kershner[2]. Furthermore, the effects are being examined of applying Kershner's procedures to animals already having the shunt.

Spleno-pulmonary anastomosis, if used in the alleviation of portal hypertension due to extra-hepatic venous block in children, would return portal blood to the left side of the heart. Calculation suggests that this would not overload the heart and would not appreciably affect oxygen saturation in the left atrium.

A parenchymatous surgical approach to the problem of portal hypertension has been described by Felder[3]. He demonstrated vascular connexions between the coapted surfaces of the decapsulated liver and spleen

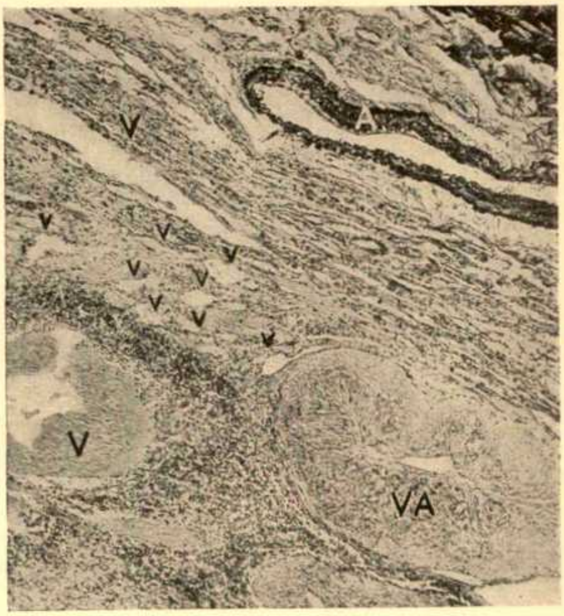

Fig. 4. High-power view (× 60) of area shown in Fig. 3, showing dilated veins in line of fusion of spleen and lung. Veins (*V*), arteries (*A*) and thickening of a vein (*VA*) probably due to anastomosis with a small artery

in rabbits, and showed that this procedure increased the time of survival following ligation of the portal vein.

A procedure in which portal blood was returned to the right side of the heart through an anastomosis between the spleen and intercostal veins has been performed in humans by Turunen[4]. Following the placing of the intact spleen inside the thorax, venous connexions developed between the spleen and the pleura, and bleeding œsophageal varices improved. We suggest that spleno-pulmonary anastomosis as a shunt in portal hypertension should prove superior.

Parenchymatous anastomosis may possibly provide a better method of treatment of portal hypertension in children than the present unsatisfactory procedures.

BIOCHEMICAL MECHANISM OF LESION FORMATION IN VIRUS-INFECTED PLANT TISSUES

By Dr. F. SOLYMOSY, Dr. G. L. FARKAS and Dr. Z. KIRÁLY
Research Institute for Plant Protection, Budapest

THE formation of local lesions is one of the most striking symptoms of virus diseases discovered as early as 1929 by Holmes[1]. Strangely enough, little is known about the metabolic disorders leading to the development of these necrotic spots. They are regarded as 'protective mechanisms' localizing the pathogenic agent to restricted areas of the host tissues due to the total disorganization and breakdown of protoplasmic structure in a small group of host cells highly sensitive to the invading parasite[2]. The local lesions of various host plants attacked by special virus strains and those of resistant wheat plants infected by rust fungi are the most typical examples of lesion formation due to 'hypersensitivity'[3]. Recent ideas concerning the metabolic aspects of defence reactions based on hypersensitivity in resistant wheat plants emphasized the probability that the balance of oxidizing and reducing systems acting on polyphenols is upset in the diseased areas, resulting in the accumulation of toxic polyphenol oxidation products killing the host tissues[4]. Experimental evidence in support of this view has recently been presented by Király[5]. It seemed, therefore, worth while to extend these studies to the problem of virus-induced lesion formation.

The leaves of experimental plants (*Nicotiana tabacum* var. Samsun, *N. glutinosa*, *Datura stramonium*) were inoculated mechanically at an early stage of development (6–8 leaf stage) with tobacco mosaic virus, cucumber mosaic virus or tobacco necrosis virus. When the local lesions appeared (second or third day after inoculation) polyphenoloxidase activity was measured in tissue homogenates by the use of conventional manometric techniques. The catechol–hydroquinone system[6] was chosen as substrate. The results are expressed as Q_{O_2}-values: increase in uptake of oxygen on addition of substrate in mm.^{3} oxygen/mgm. dry matter/hr. As a gradual decrease in activity of polyphenoloxidase was experienced in the course of measurements, results were calculated on the basis of readings taken during the first 10–15 min. Representative examples are given in Table 1.

As shown in Table 1, a considerable increase in activity of polyphenoloxidase was found whenever the host–virus combination resulted in the appearance of local lesions, whereas no similar stimulation was observed when the virus spread systemically, except in a very late stage of systemic infection. This latter observation on systemically infected plants is in agreement with recent findings of Martin[7]. His claims for another smaller maximum of polyphenoloxidase activity in systemically infected tobacco plants at an early stage of infection, however, could not be verified using (to secure reliable controls) the half-leaf method.

Table 1. EFFECT OF VIRUS INFECTION ON THE POLYPHENOLOXIDASE ACTIVITY OF HOST TISSUES

Host plant	Tobacco mosaic virus		Tobacco necrosis virus		Cucumber mosaic virus	
	H	I	H	I	H	I
N. glutinosa	0·2	4·5*	0·2	2·1*	0·2	0·5
N. glutinosa†	—	—	—	—	5·1	9·9
N. tabacum var. Samsun	8·7	9·3	8·7	12·6*	—	—
Datura stramonium	0·6	9·6*	—	—	0·6	1·8

Polyphenoloxidase activity: expressed as increase in oxygen uptake in mm.^{3}/mgm. dry matter/hr. upon addition of substrate.

H, healthy; I, infected.

* Combinations resulting in the development of local lesions.

† Polyphenoloxidase activity tested six weeks after infection. The control was of the same age.

If the accumulation of polyphenol oxidation products, due to an *in vivo* stimulated activity of phenol oxidizing enzymes, were the immediate cause of lesion formation, this latter should be inhibited by the administration of compounds able to reduce quinones or inhibit their formation under physiological conditions. Ascorbic acid is able to reduce quinones chemically. In addition, the inhibitory effect of ascorbic acid on some polyphenolases has been reported[8]. Glutathione and cysteine are also powerful reducing compounds, and *in vitro* inhibition by glutathione and cysteine of the accumulation of polyphenol oxidation products was described[9]. Therefore, the above compounds were infiltrated into detached *N. glutinosa* leaves, the excess of water evaporated, and the leaves infected with tobacco mosaic virus. The infected leaves were then placed with their petioles in test-tubes containing the same solutions and after two days the number of local lesions counted. The results were clear-cut (see Table 2). All the three compounds, if applied in adequate concentration, strongly inhibited lesion formation (10^{-2} *M*). The most effective was ascorbic

Table 2 THE EFFECT OF REDUCING SUBSTANCES ON LESION DEVELOPMENT IN *Nicotiana glutinosa* INFECTED WITH TOBACCO MOSAIC VIRUS

Substance infiltrated	Average number of lesions*	
	Infiltrated	Control
Ascorbic acid 10^{-2} *M*	2	37
Glutathione 10^{-3} *M*	6	42
Cysteine 10^{-2} *M*	5	30

* Average of five consecutive experiments

acid, usually reducing the number of local lesions to zero

This effect is apparently based on a chemical *in statu nascendi* reduction of the quinones formed This is indicated by the fact that a high level of reducing compounds must be maintained in the tissues in order to inhibit lesion development When after infiltration with 10^{-2} *M* ascorbic acid the leaves were placed in water instead of ascorbic acid solution the treatment proved more or less ineffective due to the rapid metabolization of the compound infiltrated Direct measurements (iodometric titration) indicated that the concentration of reducing compounds of the leaves must be raised 7–8 times and maintained at this high level in order to inhibit lesion formation This explains the failure of Wiltshire[10] to obtain the inhibition of lesion development by ascorbic acid in beans infected with tobacco necrosis virus He raised the endogenous ascorbic acid concentration to a lesser extent

The concentration of ascorbic acid applied may be regarded as physiological The inhibition is evidently not due to any unspecific damage to the leaf metabolism since it is reversible Although complete inhibition is achieved by the end of the second day after infection, the lesions will later appear if the concentration of ascorbic acid is allowed to decrease With cysteine and glutathione symptoms of toxicity appeared after about 24 hr To reduce the toxic effect these compounds were infiltrated into the leaves 24–36 hr after infection Even in this case the margins of some leaves were slightly damaged The development of local lesions was, however, arrested in the unaffected areas of the leaf surface as well

The complete abolition of lesion formation in leaves treated with ascorbic acid favours the view that the development of lesions results from an accumulation of quinones due to an enhanced polyphenoloxidase activity and possibly also to a virus-induced breakdown of reducing systems in some cases The disorganization of cell structure in itself does not lead to an increased activity of polyphenoloxidase When leaf tissues of *N glutinosa* were damaged with a needle evoking 'lesions' strikingly similar to those induced by tobacco mosaic virus, the activity of polyphenolases, measured 24 hr after damaging, has not shown any increase comparable to that occurring in leaves with virus-induced lesions This is further evidence to show that the enhanced activity of polyphenoloxidase in virus-infected leaves is a cause and not a result of cellular breakdown and it is actually the mechanism responsible for the hypergic reaction localizing the pathogen and inhibiting its generalization

As judged from transmission experiments the virus did multiply in the treated tissues but this has not led to the appearance of local lesions in the presence of reducing compounds Experiments are in hand to decide whether or not a generalization of the virus occurs in this case

CRYSTALLOGRAPHIC STUDIES OF THE BIURET REACTION

By DR H C FREEMAN, J E W L SMITH and J C TAYLOR*

School of Chemistry, University of Sydney

THE bonding between metal ions and peptides is a subject of increasing biochemical interest Metal-peptide complexes appear to be involved *inter alia* in the transition-states of metal-activated proteolytic enzyme reactions[1,2], in the inhibition of the gelation of gelatine by cupric ions (ref 3 and Kiefer, M , and Vinograd, J R , private communication), and in the formation of the colours of metal-protein solutions[4-8] Hitherto, the evidence for the structures of such complexes has been drawn from measurements on solutions, since insufficient analogy exists between them and the few amino-acid chelates the crystal structures of which have been studied[9-11] We have therefore begun structure determinations of several compounds intended to be models for peptide-metal interaction In this communication we wish to report those features of two of these structures which appear to be of biochemical significance

As a starting-point we have used the well-known fact that, when cupric ion is added to an alkaline solution of a protein or polypeptide, a violet-red colour is produced The reaction is a general one, obviously involves the formation of a metal-peptide complex, and has been used in qualitative and quantitative tests for proteins The violet-red colour is reversibly changed to blue upon acidification of the solution The simplest substance which shows this behaviour is biuret, $NH_2CONHCONH_2$, and the reaction has accordingly become identified with the name of this compound

We have carried out X-ray crystal structure determinations of two substances—potassium *bis*-biuret cuprate(II) tetrahydrate, $K_2[Cu(NHCONHCONH)_2] \cdot 4H_2O$ (substance *a*), and *bis*-biuret copper(II) chloride, $[Cu(NH_2CONHCONH_2)_2]Cl_2$ (substance *b*) The former is the violet 'parent compound' of the biuret reaction It was prepared by shaking fresh cupric acetate with a solution of biuret dissolved in

---

* Present address Australian Atomic Energy Commission, Lucas Heights, New South Wales

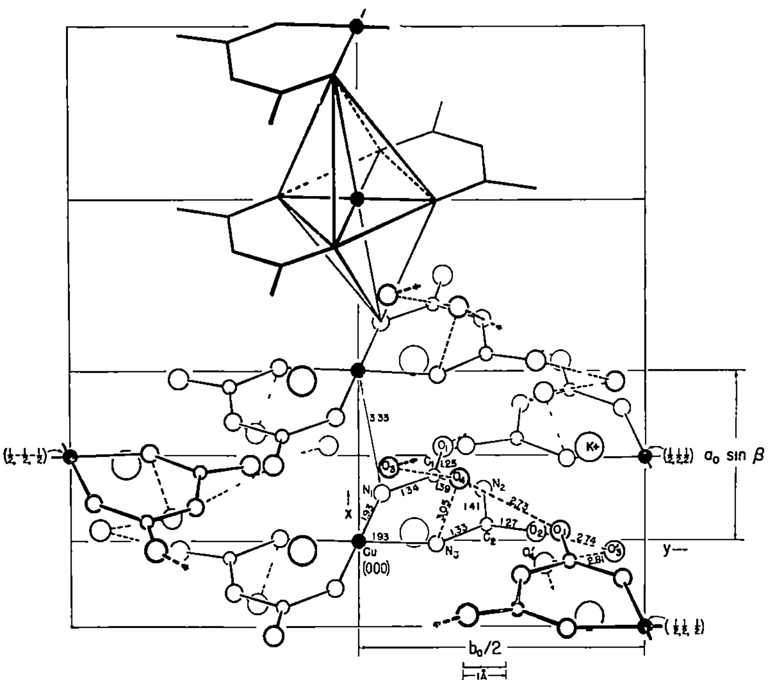

Fig. 1. z-Axis projection of $K_2[Cu(NHCONHCONH)_2]\ 4H_2O$

the calculated excess of aqueous alkali. Crystals were obtained by the slow addition of a large volume of alcohol containing a little potassium hydroxide. The second compound formed tiny pale blue-green crystals when a warm alcoholic mixture of cupric chloride and biuret was gradually cooled. Both complexes were unstable in air but the crystals were adequately protected against decomposition by a thin film of collodion.

Substance *a* is monoclinic *a* = 3·84 A., *b* = 13·32 A., *c* = 13·92 A., β = 94° 5′. The space-group is $P2_1/n$. There are two formula units in the unit cell, and these must therefore be centred about copper atoms at the origin and (½,½,½). Substance *b* is orthorhombic, *a* = 6·83 A., *b* = 8·03 A., *c* = 10·74 A. There are two formula units in the unit cell, but there is an ambiguity between the allowed space-groups *Pnn*2 and *Pnnm*. While the copper atoms are at (0,0,0) and (½,½,½) in either case, only the second of the two possible space-groups would confer centrosymmetry on the complex.

For the violet compound *a* our data consist of the absorption-corrected intensities of about 1,000 X-ray reflexions, visually estimated on Weissenberg diffraction photographs obtained with copper K_α-radiation. The structure has been refined by the method of least-squares, giving a conventional crystallographic reliability factor *R* = 0·079 and standard-deviations of the bond-lengths and bond-angles of about 0·01 A. and 1·6° respectively. The parameters for the anisotropic thermal vibrations of all the atoms (other than the hydrogens) have been computed. The final refinement cycles have produced evidence for the locations of the hydrogen atoms, and it is on the basis of these that we can assign to the compound the formula given above (as distinct from, for example, $K_2[Cu(NH_2CONHCONH_2)_2](OH)_4$). The structure analysis of substance *b* has progressed to the stage where there is no doubt about the general structure. With a single isotropic temperature parameter for all atoms the *R*-factor is 0·127 for 429 *hKl* reflexions (*K* = 0–4), of which one-third were unobservably weak; for those 176 reflexions to which the copper atom makes no contribution, *R* is 0·152. The two structures are shown diagrammatically in Figs. 1 and 2, which are projections along the *z*-axis of *a* and the *x*-axis of *b*, respectively.

The copper atoms are square-co-ordinated in both complexes. In the violet compound *a*, the square-planar arrangement of ligand atoms involves the peptide nitrogen atoms N_1 and N_3 of two symmetrically placed biuret residues. The bonds have reasonable Cu—N lengths of 1·93 A. Successive complexes are stacked at such an inclination to the (100) plane that each nitrogen atom N_1 of one complex also lies exactly at one of the apices of an elongated octahedron about the copper atom of an adjacent complex. The arrangement is illustrated in the upper half of Fig. 1. The distance between the copper and the octahedral nitrogen atoms is 3·33 A., implying that only weak interaction is possible. The closeness of approach between complexes has, of course, a

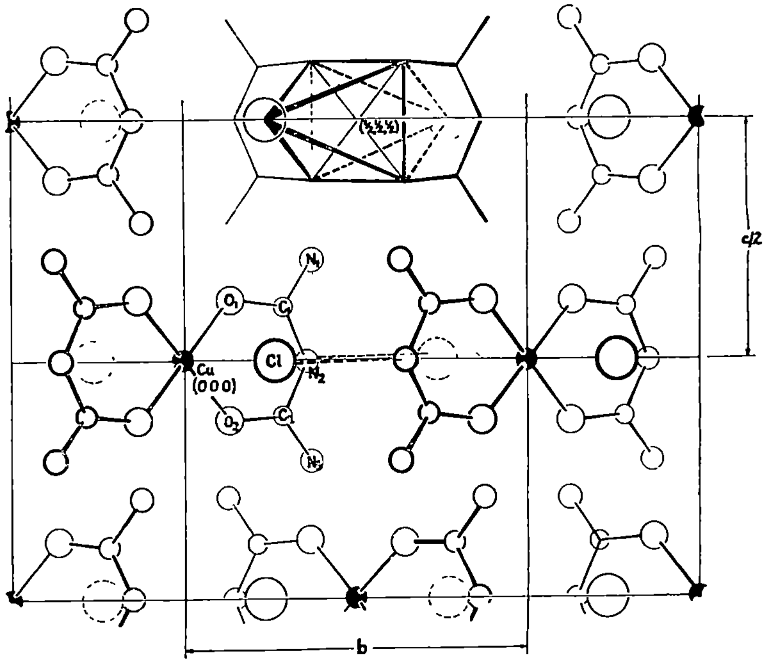

Fig. 2. x-Axis projection of $[Cu(NH_2CONHCONH_2)_2]Cl_2$

lower limit set by the van der Waals' radii It turns out that the Cu—N vector represents the shortest distance between any two atoms of adjacent complexes

The bond-lengths and bond-angles of the amide-groups in *a* are not significantly different from those reported for the biuret molecule in the crystal of biuret hydrate[12] This indicates that the substitution of a co-ordinated copper for an amide hydrogen atom does not seriously disturb the bond-orders and resonance in the amide group As in biuret hydrate, so in *a* the biuret residue is not flat Each biuret residue is bent slightly about the line joining Cu to N_2, the two halves then being twisted in opposite senses about the bonds C_1—N_2 and C_2—N_2 As a result of this distortion there is an angle of about 5° between the normals to the two planes containing, respectively, $N_1C_1O_1N_2$ and $N_2C_2O_2N_3$ Neither amide group lies strictly in the plane of the copper atom and the four attached nitrogen atoms In fact, even if we ignore the non-planarity of the two biuret molecules co-ordinated to a copper atom, the complex is bent by about 2 5° on each side of the co-ordination square along the line adjoining N_1 and N_3 of the ligand

The water molecules and amide groups in substance *a* are linked by a network of hydrogen bonds, albeit not a particularly efficient one If we superscribe the atoms of the complexes centred on $(-\frac{1}{2},\frac{1}{2},-\frac{1}{2})$ and $(\frac{1}{2},\frac{1}{2},-\frac{1}{2})$ with ′ and ″ respectively, then hydrogen bonds link O''_2 O_3, O_3 O_4, O_4 N_3 and O_4 O'_1 The potassium ion fits into a hole in the structure (a fact which does not emerge very clearly from Fig 1), being at the centre of a trigonal prismatic arrangement of four amide oxygen atoms and two water molecules at K^+ O distances between 2 7 and 2 9 A

A closer examination of the configurations about the ligand nitrogen atoms in *a* leads to the important conclusion that considerable distortions from the normal bond-angles may occur at the sites of co-ordination The angles Cu—N_1—C_1 and Cu—N_3—C_2 are both 131° The vector from N_1 to the copper atom of an adjacent complex makes an angle of approximately 90° with both the N_1—Cu and N_1—C_1 bonds The hydrogen atoms which are attached to N_1 and N_3 do not appear to be involved in hydrogen bonds, and their *x*-co-ordinates are not in fact as accurately known as the other hydrogen-parameters in the structure These two hydrogen atoms appear to lie only slightly out of the plane of the copper and nitrogen atoms Approximate values of the bond-angles are Cu—N_1—H, 119° , C_1—N_1—H, 108° , Cu—N_3—H, 112° , C_2—N_3—H, 115° This places the hydrogen atom attached to N_3 on the line between N_3 and the water-O_4 atom of the next unit-cell in the $-x$ direction, although the distance of 3 35 A makes it unlikely that a hydrogen bond is here involved N_3 is, on the other hand, definitely hydrogen-bonded to the water-molecule represented in Fig 1 by O_4 This N_3 O_4 bond lies at angles of 112° and 94° from the bonds N_3—Cu and N_3—C_2

The blue compound *b* also has two biuret molecules bonded to each copper atom via four donor atoms arranged at the corners of a square In this case the octahedral positions are occupied by chloride ions at normal Cu—Cl^- distances of 3 0 A , while the donor atoms at the present level of refinement appear to be at 1 92 A from the metal atom

The most interesting difference between *a* and *b* is that in $[Cu(NHCONHCONH)_2]^{=}$ the metal-peptide bonding is via the peptide *nitrogen* atoms, while in $[Cu(NH_2CONHCONH_2)_2]^{++}$ at least two, probably four, of the donor atoms are peptide oxygen atoms At every refinement stage we have recalculated all structure-factors for models having as the ligand atoms respectively four oxygen atoms, two oxygen and two nitrogen atoms, and four nitrogen atoms The agreement between the calculated and observed structure-factors for the first of these models has been consistently and significantly better than for the third, and consistently and slightly better than for the second

At the present stage of refinement of *b* a more detailed description of the ligand is impossible It is quite clear, however, that the complex is bent similarly to *a*, and that the plane of each biuret molecule makes an even larger angle (of about 23°) with the plane containing the copper and donor atoms

By contrast with *a*, the structure of *b* is held together mainly by the electrostatic forces between the complex cations and the chloride anions The only certain hydrogen-bonded contact is that between the secondary nitrogen atom N_2 and a chloride ion which lies at 3 2 A , almost exactly along the line which bisects the angle C—NH—C The complexes lie perpendicular to (001), and a projection of the structure along the *z*-axis would show the compact arrangement of complexes and Cl^- ions in this plane

It has been pointed out by Rabin[16] that, unless a peptide hydrogen atom is lost by dissociation, co-ordination at a peptide nitrogen atom causes the loss of the resonance energy of an amide group Under neutral or acid conditions, co-ordination at the peptide oxygen atom is therefore expected At first sight, this view gains strong support from the structure of *b*, which is precipitated from a neutral alcoholic solution We have not, however, succeeded in showing that the ion $[Cu(NH_2CONHCONH_2)_2]^{++}$ indeed exists in other than the solid state A neutral aqueous mixture of cupric sulphate and excess biuret has an absorption curve between 200 and 1,000 mμ which is indistinguishable from that of the hexaquo-copper(II) ion, and the absorption curve of an alcoholic solution of cupric chloride between 230 and 1,000 mμ is unaffected by the addition of alcoholic biuret solution until precipitation occurs

On the other hand we find, in agreement with Kober and Haw[17], that the violet complex *a* in aqueous solution has an absorption maximum at $\lambda_{max} = 505$ mμ with $\varepsilon_{max} = 43$ The structure analysis thus provides evidence that absorption at this wave-length is indeed characteristic of copper(II) co-ordinated by four peptide nitrogen atoms[8a,17], it being assumed that the complex *a* has the same structure in solution as in the solid (with the probable addition of two water molecules in the octahedral positions)

Finally, our results for the first time confirm a structure which was suggested for the violet copper–biuret complex by Tschugaeff in 1907 [4] They also support the view[1,13,15,16] that in alkaline solution the ionization of peptide hydrogen atoms is responsible for the additional dissociation constants found for the copper complexes of some peptide ligands, and that metal-peptide binding then occurs via peptide nitrogen atoms

Detailed descriptions of the structures and particulars of the methods of refinement are being published elsewhere Concurrently with the further refinement of *b* we are investigating the crystal structures of the cupric complexes of tri- and tetra-glycine with the intention of initiating a systematic attack on the structural questions involved in metal-peptide systems via suitable model compounds

Parts of this work were carried out during the tenures of a George Ellery Hale fellowship at the California Institute of Technology (H C F), and of an Australian Atomic Energy Commission studentship (J C T) Our first crystal specimens were given to us by Dr B M Gatehouse and Dr R J Irving (University of New South Wales) Helpful discussions with them and with Drs A McL Mathieson, B R Rabin, T M Dunn and R W Green are gratefully acknowledged

COLOUR-IMAGE SYNTHESIS WITH TWO UNORTHODOX PRIMARIES

By ARTHUR KARP

Engineering Laboratory, University of Cambridge

DR E H LAND, in his recent articles[1,2] and interesting lecture to the Royal Photographic Society last year, has revived interest in the art of synthesizing coloured images with only two primaries The technique is to superpose on a screen the images of two black-and-white slides contained in two projectors having individual coloured light sources The slides for the two projectors, here designated L and S, are always prepared by photographing a scene through red and green filters so that the transparent areas of each slide correspond to light reflected from the scene in the spectral intervals red-to-yellow, and yellow-to-cyan (blue-green) respectively The choice of hues for projection, or for the dyes or inks to be printed on film or paper, however, is open The standard combination, as used in 'Sovcolor', the original 'Warnercolor' and their numerous predecessors[3], is red-orange and blue-green Fox and Hickey, more than fifty years ago, and the Raycol Company, in 1929, employed red and white[3]

By studying these and very many other pairs of projecting primaries in careful experiments, Land has been able not only to create some effective colour pictures, but also to report some new and accurate measurements For example, a surprising gamut of hues, including red, white and blue, may be seen when the S illuminant is greenish-yellow (dominant wavelength $\lambda_S = 579$ mμ) and the L illuminant is orangish-yellow ($\lambda_L = 599$ mμ) With regard to other primary colours, the number of different hues that may or may not be visible in the final result is a function of the primaries To summarize his findings, Land has designated, on a chart having λ_S and λ_L as co-ordinates (ref 2, p 89), hereinafter referred to as Land's colour map, domains indicating the unobtainable final subjective hues To summarize his investigations of how each hue is produced in an image, Land constructed another chart, called the dimensionless co-ordinate system (ref 2, 89), where the names of all the hues are attached to points the co-ordinates of which are the relative L and S illuminations of a spot in a synthesized picture where the particular colour was seen Relative L illumination is defined as the actual intensity of L light at the spot divided by the maximum intensity of L light anywhere in the picture

Many of the above facts have been verified by experiments at the Cambridge University Engineering Laboratory For example, the red-and-white primary combination does allow bluish and greenish hues to appear on the screen, or in a Kodachrome photograph of it, although detailed examination of each image point in isolation reveals nothing but mixtures of red, white and black, even in regions which take on bluish or greenish hues when the isolation is incomplete The term 'in isolation' denotes that an image point is examined by a means which excludes the remainder of the image, including details, such as a highlight, of the object of which the point is a part It also denotes that the eye has not been exposed to any coloured fields immediately prior to the observation

Land has also reported[1 2] that nothing but shades and tints of red can be seen when the S and L slides are wedge filters, giving a gradual change from black to white, oriented as in Fig 1*a*, so that the gradations run from top to bottom in one projector and from left to right in the other We modified this experiment by using stepped wedges overlaid by either a black or a white network to form detached squares against a background (Fig 1*b* and *c*) The results in *b* were monochromatic as in *a* , but with the white network *c* bluish-green hues dramatically appeared in the positions indicated Points of the network, or background, were pink when viewed in isolation through a small-apertured telescope, but in context appeared quite white The bottom right-hand square was white in isolation, but cyan—the complementary of red—in context Gelatine filters of various colours were then inserted in either or both of the projectors Without a white background, only mixtures of the original primaries were seen Against the white background, colours that were easily recognized as mixtures of two new primaries became visible Each new, or revised primary, was in turn recognized as one of the original primaries mixed with the

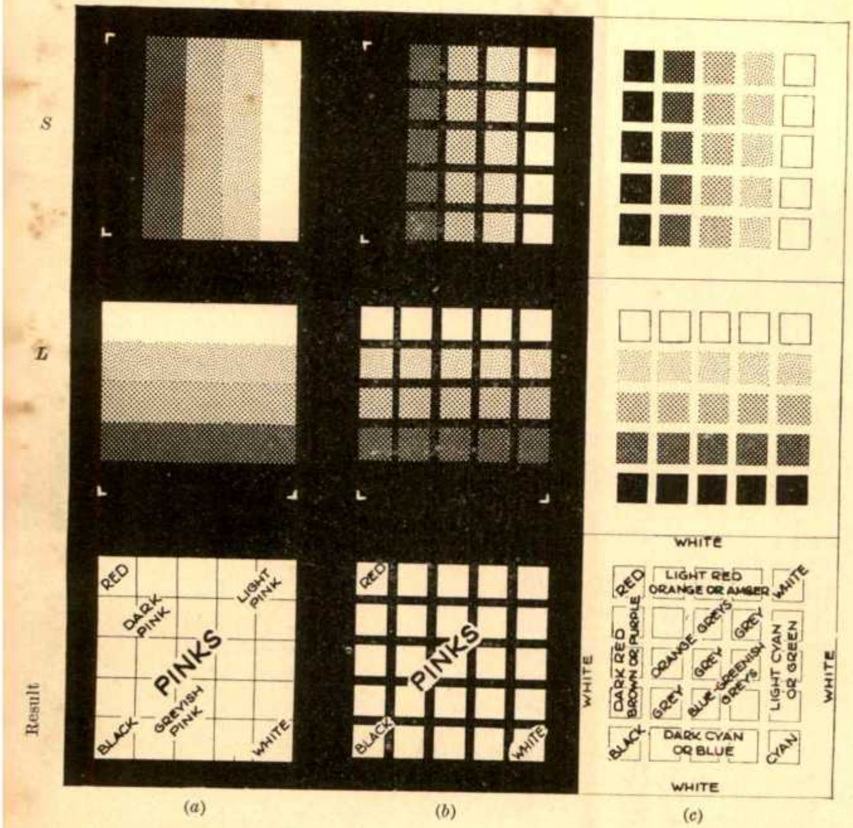

Fig. 1. Method of projecting array of squares with slides of horizontal and vertical step wedges. *a*, No background; *b*, black background; *c*, white background. Top row: slides for *S* projector; second row: slides for *L* projector; bottom row: subjective result with red *L* and white *S* primary illuminants

complementary of the other. This prevalence of complementary-hue generation strongly suggests that the physiological and/or psychological effects that occur in unorthodox two-colour synthesis are probably related to those which occur in simultaneous or successive contrast, as in the striking experiment wherein a red light instantly appears cyan—or a green light, magenta—when viewed through a hole in a rotating disk the surface of which is half white and half black.

The remarkable contribution of the subjectively white background suggested other experiments with white cues. Whatever the primary hues, it was found that a synthesizable composition had to include areas which were psychologically more acceptable when neutral, such as a border or background which could be white or grey or even a rather dark grey. Excellent, though subtle, white cues are the highlights on glossy objects. Though very small they are hard to avoid in natural scenes other than landscapes, and, regardless of the colour of the underlying object, may provide the most intense white in the entire composition, as artists and television camera-men will confirm. The tolerance on mis-registration of the two constituent images was found to be related to the loss of identity of the tiny highlights in the scene.

Only occasionally did the masking-off of all white cues fail to remove completely the impressions of cyan in a red-and-white synthesis. Even then, the residual impression usually faded away after several seconds. If it did persist, it was when red areas were nearby and simultaneous contrast was occurring. In this case the residual cyan would vanish after a pale blue gelatine filter was passed in and out of the beam of the *S* projector—a procedure which had no effect on a picture containing white cues.

In each screen image, whether a still life or abstract composition, much was learned by watching (1) the *warmest spot*, (2) *coolest spot* and (3) *white cue*, as the primary colour filters were changed and/or intensities of illumination varied. These three regions receive maximum light from (1) the *L*-projector alone, (2) the *S*-projector alone, and (3) both projectors, respectively, and may thus incidentally be associated with the datum levels of Land's dimensionless co-ordinate system. As the relative intensities of the primaries were varied, the subjective colour of the white cue appeared as a *desaturated* version of their mixture, and for many primary pairs, a point could be reached when the white cue object or region appeared as a "very good white". In brightness and hue, the apparent colour of the warmest spot was recognized as that of the *L* projector's light mixed classically with the complementary of the *S* projector's light, the intensity of the second component being small or large accordingly as the *S* projector's light was relatively dim or bright. For the coolest spot, read the foregoing sentence with *S* and *L* interchanged.

These results can be described more quantitatively with the help of the classical C.I.E. chromaticity chart[4]. As an example, Fig. 2*a* has been drawn for one of the remarkable pairs of primaries used by Land[2]—greenish-yellow *S* (579 mμ) and orangish-yellow *L* (599 mμ). Intensity is measured perpendicular to the page, so that the chart represents lines and planes in colour space projected into the plane having medium neutral grey at O. All the physical chromaticities of the projected scene lie in the line *LS*. As light intensities are varied, the physical chromaticity of a white-cue spot (*W*) obviously moves along *LS*, but its subjective chromaticity is seen to depart from *LS* and follow the dashed curve *LW'S*. The separation O*W'* at the closest approach to O is exaggerated in the figure, for it is usually small if *W* originally falls in a yellow or other light or desaturated region of the chart. The reason for the shift of *W* to *W'* is probably psychological, and may be accompanied by a physiological process giving involuntary and rapid adjustment of the sensitivities of one or more of the retinal or cortical colour sensors in the direction of restoring the neutrality of hue of the parts of the image which the observer, perhaps subconsciously, expects or prefers to be neutral. (In projecting conventional colour transparencies, one may also observe the tendency to retain the whites and greys in the original picture when a flood of coloured light is superposed.) Possibly because of retinal or cortical

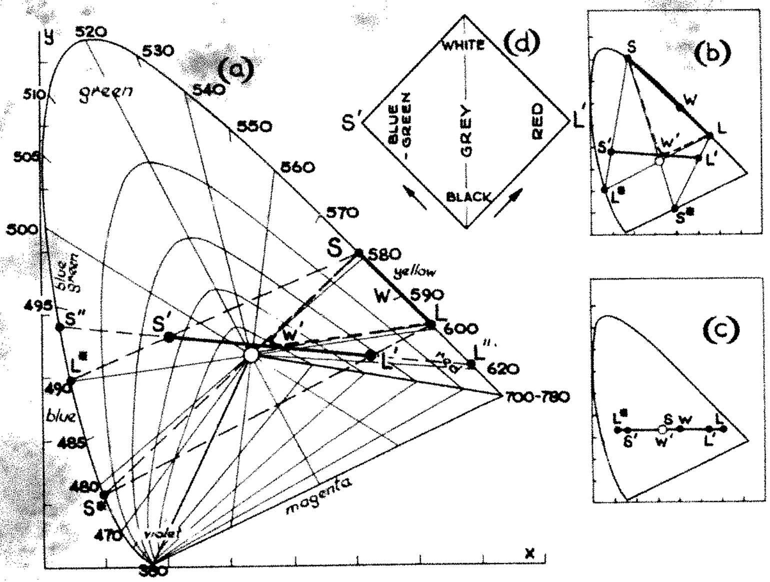

Fig. 2. Transformation of physical locus of chromaticities (SL) to mental locus of chromaticities ($S'L'$) via the white-cue effect. *a*, Primaries 579 and 599 mμ; *b*, primaries 535 and 589 mμ; *c*, primaries white and orangish-red; *d*, final colour plane

interconnexions, the observer's controls seem to act as well over the remainder of whatever scene is sharing a common frame with the white cues, and the effect is one of partial subtraction of the original primaries over the area within this frame.

The subjective chromaticity of the warmest spot lies at L' between L and the complementary of S, that is, S^*. The distance LL' increases as the relative intensity of S is increased. Similarly, the coolest spot's chromaticity S' lies on SL^*, with $SS'/S'L^*$ depending on the ratio of the intensities of L to S, which is set when adjusting for the best rendering of white and grey. The subtractions have produced revised primaries, S' and L', and a revised locus, $S'W'L'$—virtually $S'OL'$—for all the subjective hues of the scene which, at the price of desaturation, is seen to embrace a much larger range of hues than SL (ref. 2, p. 86). Replacement of the monochromatic primaries with gelatine-filtered light of the same dominant wave-lengths shifts S, L, S^* and L^* to points slightly inside the spectrum locus, with little effect on the result. Similar diagrams (Fig. 2*b*) are readily constructed for any other primary combination including those in which one member of the pair is white (Fig. 2*c*). The colours in $S'L'$ are all desaturated to roughly the same extent, so that one usually obtains a pleasingly restrained and dignified[3] artistic effect like that of a water-colour painting. Primaries such as S'' and L'', for example, lead to similar final hues; but the effect can be harsh or gaudy.

When $S'L'$ is roughly parallel to the x axis, Land's co-ordinate system can be related to the plane through $S'L'$ normal to the page (Fig. 2*d*). For other orientations of $S'L'$, the hues lying far from $S'L'$ correspond to those stated to be unobtainable in Land's colour map. For example, when $S'L'$ runs from blue to yellow, it gives wide berth to red, green and magenta. When the primaries are blue L (440–510 mμ) and violet S (400–435 mμ), the construction makes S' and L' fall in the magenta and green regions, respectively. Not only are all other hues now unobtainable, but the revised cool primary S' is now warmer (redder) in aspect than L'. (See the region marked "short wave reversal" in Land's colour map.)

A final problem concerns the fact that some of the colours, such as yellow, purple, deep blue, etc., which are sometimes seen in synthetic still life and other compositions, do not lie within $S'L'$ (Fig. 2*d*) which, to use an analogy, has only "four paints on its pallette"—red, cyan, black and white. Numerous experiments with many observers suggest that a psychological factor, probably related to the effect of the picture on the observer's emotions, determines whether the subjective colours will be limited to those of $S'L'$ or whether hues from closely adjoining regions in the C.I.E. chart may be co-opted by the imagination. For example, with synthesized pictures of most geometrical patterns, or of an uninteresting collection of variously coloured but otherwise identical polished plastic spheres, no colours outside the limited range of $S'L'$ were noted in the projected image by indifferent observers to whom no suggestions were given. However, if suggestions were given, or if the scene possessed the least trace of human interest, $L'S'$ colours such as cyan, dark desaturated cyan, light pink and dark grey might convincingly appear to some observers, respectively, as a green, blue, yellow and violet of the same lightness, and a low-intensity red could sometimes appear either as chocolate, claret, mahogany, or purple. When viewing the array-of-squares projections (Fig. 1*c* bottom) some observers reported seeing spectral sequences in the rows or columns and named individual squares as amber, orange, purple, indigo, etc. Unanimous agreement among normal observers, however, could only be approached when the objects actually were of an $L'S'$ colour, or when they had an established identity, such as daffodils, ivy leaves, a croquet set, hair, sky, a Chinese teacup, etc.

To conclude, we believe that, in conjunction with the phenomenon of overlapping in the subjective distinctions between colours of equal lightness and adjacent hue, the white-cue effect—which, in restoring the sensations of white and grey to a framed image, causes the original primaries of that frame each to be modified by the addition of the complementary of the other—adequately explains the various phenomena associated with the unorthodox two-colour synthesis of images of natural objects.

I am indebted to Prof. W. R. Hawthorne for his generous sponsorship and encouragement of the project and many helpful discussions and suggestions. The valuable comments of Dr. W. A. H. Rushton and Dr. E. N. Willmer are gratefully acknowledged, as is the technical assistance of Messrs. E. R. Mudd, E. D. Nisbet, L. R. Peters and the staff of the Engineering Laboratory Workshop under A. A. Barker. Thanks are also extended to the scores of observers whose comments are a necessary part of any subjective study.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, October 26

Royal Geographical Society (at 1 Kensington Gore, London, S W 7), at 5 p m —Prof Michael J Wise "Great Cities of Japan"

University College (in the Physiology Theatre, Gower Street, London, W C 1), at 5 30 p m —Prof A Fleckenstein (University of Freiburg) "The Metabolism of Labile Phosphate Compounds in Living Muscle, Studied with Radioactive Phosphorus and Paper Chromatography" (First of two lectures on "Isotopic Studies of Phosphorus Metabolism in Skeletal and Heart Muscle" Further lecture on October 28)*

University of London (at Birkbeck College, Malet Street, London, W C 1), at 6 p m —Prof E G Boring (Harvard University) "Current Trends in American Psychology" (Last of three lectures on "The Pattern of Modern Psychology")*

Tuesday, October 27

University College (in the Anatomy Theatre, Gower Street, London, W C 1), at 1 15 p m —Dr Elizabeth M Deuchar "How Embryos Develop—Grafting Experiments and the Organiser Concept" *

Institution of Electrical Engineers, Measurement and Control Section (at Savoy Place, London, W C 2), at 5 30 p m —Discussion on "Future Trends in Memory Stores for High-Speed Digital Computers", opened by Mr W Renwick

Illuminating Engineering Society (at the Federation of British Industries, Tothill Street, London, S W 1), at 6 p m —Mr A N Irens "Light and Productivity" (Golden Jubilee Lecture)

Institution of Mechanical Engineers, Automobile Division (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Mr Leonard Raymond "Engineering Challenges to American Automotive and Petroleum Research"

Society of Instrument Technology (at Manson House, 26 Portland Place, London, W 1), at 7 p m —Mr J H Bach and Mr G E Fishter "Modern Developments in Optical Instruments"

British Association for the Advancement of Science, in association with Granada TV Network, at the Guildhall, London, E C 2), at 8 30 p m —Sir Eric Ashby Third of the Inaugural Series of the Granada Lectures on the theme of "Communication in the Modern World"

Wednesday, October 28

Institution of Electrical Engineers, Electronics and Communications Section (at Savoy Place, London, W C 2), at 5 30 p m —Mr M J L Pulling "Development of Eurovision" (Chairman's Address)

Institution of Mechanical Engineers, Applied Mechanics Group (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Prof J L M Morrison, Prof B Crossland and Dr J S C Parry "Strength of Thick Cylinders Subjected to Repeated Internal Pressure"

Society of Chemical Industry, Food Group—Nutrition Panel (at 14 Belgrave Square, London, S W 1), at 6 15 p m —Mr A E Bender and Mr B H Doell "The Nutritionist and the Food Industry"

Thursday, October 29

University College (in the Anatomy Theatre, Gower Street, London, W C 1) at 1 15 p m —Dr G E Fogg "Life on Mars" *

University of London (at the Imperial College of Science and Technology, London, S W 7), at 1 30 p m —Mr S J Gould "Industry and Society 1—The Sociologists Look at Industry" * (First of five lectures Further lectures on November 12, 19, 26 and December 3)

University of London (at the Senate House, London, W C 1), at 5 30 p m —Dr Kenneth M Smith, C B E , F R S "Recent Work on the Electron Microscopy of Viruses" *

Institute of Physics (at 47 Belgrave Square, London, S W 1), at 6 p m —Prof G O Jones "New Uses for Low Temperatures"

Friday, October 30

University of London (at the Institute of Neurology, National Hospital, Queen Square, London, W C 1), at 5 30 p m —Dr Paul C Bucy (Chicago) "Neural Mechanism Responsible for the Control of Motor Activity"

Royal Institution (at 21 Albemarle Street, London, W 1), at 9 p m —Mr F C Bawden, F R S "Plant Viruses What They Are and What They Do"

Saturday, October 31

Society for Forensic Science (in the Lecture Theatre, Portland Building, University of Nottingham), at 10 a m and 2 p m —Inaugural Meeting

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Fellow or Senior Fellow in Philosophy within the Department of Social Philosophy, Australian National University, Canberra—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, November 10)

Assistant (with a degree in botany or horticulture or equivalent, and preferably experience in microscopy, and mathematical ability) in the Pomology Section, for work on plant anatomy—The Secretary, East Malling Research Station, near Maidstone, Kent (November 15)

Chair of Metallurgy in the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (South Africa, November 15)

Biochemist (with two or three years research experience in agricultural chemistry, and preferably with M Sc or Ph D qualifications), for duties which include supervision of routine soil and plant analyses and research on the composition and properties of tobacco—The Director, Tobacco Research Board of Rhodesia and Nyasaland, P O Box 1909, Salisbury, Southern Rhodesia (November 16)

Senior Lecturer, Lecturer and a Senior Demonstrator in Physiology at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, November 16)

Lecturers or Assistant Lecturers in Botany, Chemistry, Geography, Mathematics and Zoology at the University of Malaya, Kuala Lumpur—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (November 20)

Chair of Anatomy tenable in the Newcastle Division of the University—The Registrar, University Office, 46 North Bailey, Durham (November 21)

Lecturer in Civil Engineering at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, November 27)

Lecturer (with qualifications in either pure or applied mathematics) in Mathematics at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (New Zealand, November 30)

Mycologist (with a good honours degree in botany with mycology as a special subject, a knowledge of the more fundamental aspects of animal and human mycoses, and preferably with a knowledge of Latin and other languages) at the Commonwealth Mycological Institute, Kew—The Secretary, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Bucks (November 30)

Biochemist (with M Sc or higher university degree), for work in the field of plant nutrition, with special reference to micro-elements and enzyme activity—The Director, Cawthorn Institute, Nelson, New Zealand (December 15)

Chair of Geography in the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (New Zealand, December 15)

Assistant or Associate Professor of Pathology at Queen's University, Kingston, Canada—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1

THE STUDY OF MAN

DESPITE comments during recent years that the British Association for the Advancement of Science appeared to have lost both its bearings and its impetus, it has been generally acknowledged that the presidential address has always been much more than a rallying call at an annual meeting; it has increasingly come to be recognized as a statement by a leading man of science to the nation. In these addresses, each president has considered a theme which often has reflected outstanding interests of men of science at that particular time. In a discipline which daily grows more complex and bewildering, Sir Edward Appleton at Liverpool pleaded with men of science to make themselves intelligible to the layman; without an informed populace he showed that science could not flourish. At the Dublin meeting, Prof. P. M. S. Blackett was concerned with the need for applying science and technology on a world-wide front to solve world-wide problems of poverty and distribution. With his own travels as background, Prince Philip at Edinburgh discussed international aspects of science and how they could contribute to better understanding between peoples everywhere. Now, in a world where powerful blocs have realized that material strength alone is not enough, this year's president, Sir James Gray, invites men of science everywhere to pay full regard to moral principles and the social repercussions of their discoveries (see p. 35 of this issue).

The address is noteworthy for a number of features. First, because Sir James Gray has looked at science as a whole and has supported his arguments by evidence drawn from a number of the sections which comprise the British Association; he himself has acted as a link between them. Secondly, because he has used the life-science of biology to show its unifying influence in the overall study of man and, thirdly, because he has used his own wide background to examine defects in the educational system before making suggestions both for spreading and applying knowledge of science and technology throughout the world and for making it part of the general philosophy of man. Like others in this famous series, his address will be long remembered as a contribution to man's general evolutionary progress.

Two of Sir James's general topics will command widespread support. The ever-present need to consider the beneficial effects of science on international relationships is made very difficult in a world where science is primarily seen as a manufacturer and distributor of hydrogen bombs; Sir James is emphatic that the primary objective of men of science should be to illuminate the beauty of science, its inflexible pursuit of truth, its challenge to courage and tenacity and its power to inspire.

The place of science in a general philosophy of life is equally well put. Like music, science knows no barriers, and the combined efforts of scientists throughout the world are necessary if man is to continue in his efforts to unravel the secrets of Nature. Where there are political restraints, where knowledge is bounded materially and mentally by local and national barriers, the man of science can provide a bridge which should encompass the Earth. Missiles should be guided, not to destroy mankind, but to bring fresh delight in making clearer the mysteries of the heavens.

To make wise and humane use of science, as Sir James rightly points out, something more than statistics or the precise laws of physics and chemistry will be required. The challenge is to the less well-defined biological sciences and to the ill-defined social sciences arising from them. These sciences must be vigorously pursued not only to discover more of man himself, but also of his relationships with his fellows everywhere; they must also be more widely taught so that more and more people have better opportunities for understanding themselves and other people. Sir James is right to emphasize that it is in the biological and social sciences that the answer may be found as to whether or not science has real cultural significance. In his address, the new president of the British Association also shows the practical nature of the biological sciences, and that man still has much to learn from his evolutionary predecessors. Students of aeronautics, navigation and communications would hasten further discoveries if they paid more attention to biology. It could be added that many students of the humanities and of the physical sciences could considerably reduce the cost of the National Health Service if they would but study some of the general principles of biology; in so doing they would improve their health and, presumably, their happiness.

In the field of demography, Sir James uses his own arguments to give full support to conclusions put forward by Prof. Blackett in Dublin. With evidence drawn from the study of natural evolution, he clearly and courageously puts his choice before all civilized beings. Accepting the discipline of voluntary limitation of families, man can direct the course of his own evolution without the evil consequences of over-population; if he "behaves like an animal and allows his population to increase while each nation steadily increases the complexity and range of its environment, Nature will take her course and the law of the jungle will prevail". Churches throughout the world should examine their doctrines to see whether they are spiritually justified in bringing misery and destitution to so many people, and whether they are indeed helping man to achieve the highest moral and spiritual development of which he is capable. Men, Sir James says, really ought to be able to do something better than ants.

In another comparison of man and animals, Sir James again shows the practical advantages which deeper study of the biological sciences could bring. Study of the learning process has revealed five basic principles, all of which could be applied to the training of human beings. These principles could be made much more use of by teachers everywhere and could revolutionize existing training methods in industry, adoption of these principles could so influence productivity that the well-being of many under-privileged peoples could be improved The all-too-prevalent rule-of-thumb methods used to control industry, which were described by Sir Alexander Fleck at Glasgow last year, would quickly disappear if Sir James Gray's biological principles were widely adopted in education and training

From his own education and experience, Sir James treads a well-worn path in pleading for a wider outlook in the teaching of science Where the majority of children are still leaving school without any real acquaintance with science, it is right that the president of the British Association should support his predecessors in advocating the teaching of science to more children more often Adults, too, should not be neglected, and much responsibility rests on existing and projected area organizations of the British Association In those areas where they have already gone to work they have taken on their tasks with enthusiasm and energy They can do much to support their president and to make the British Association once more regarded not only as an organization which holds an annual meeting, but also as the spearhead for spreading interest in science throughout Great Britain In so doing they can also help the British people to understand more deeply the meaning of democracy and to accept the responsibilities it brings

THE IMPORTANCE OF BEING HUMAN

The Importance of Being Human
Some Aspects of the Christian Doctrine of Man
By E L Mascall Pp vii+118 (London Oxford University Press, 1959) 10*s* 6*d*

A BOOK on the Christian doctrine of man in the light of modern science can at least be said to have a subject of vital concern to all who care for religion Though Dr Mascall has not written a comprehensive treatise, he has dealt with some of the fundamental questions, and it need not be added that he is well equipped both by his knowledge of science and his theological learning for the task

There are two kinds of book on this topic, one that is prepared to modify or 're-interpret' the Christian dogmas and the other that defends them with no accommodation to modern thought Dr Mascall's book belongs to the latter class Though, of course, he is ready to restate the doctrine of the Church to make it more intelligible, he will not contemplate any radical revision He writes as one who accepts an Aristotelian metaphysic, in the main according to the theistic version of St Thomas, and regards the tradition of the Christian Church as revealed truth It is to be hoped, however, that these presuppositions will not deter readers from attending to what he has to say, for he touches on problems that need to be faced The modern man's difficulty about understanding his nature and status in the universe, Dr Mascall thinks, is largely due to the fact that science appears to allow him no "special and assigned status" and no "definite and determined nature" Scientific discourses on the uniqueness of man really leave the ordinary man in the dilemma that he does not have any clear idea of what being human means He was better off in this respect when he could be satisfied with the assurance that man is the "rational animal" Dr Mascall rejects the suggestion that man may be a stage in the evolution of some higher kind of being The Incarnation, he holds, must prohibit any Christian from regarding man as a stepping-stone to some superman "If the Christian religion is true, we have quite solid reasons for holding that, whatever developments man is meant to undergo, man is meant to remain man , for, if God has himself become man in the Incarnation, he has sealed human nature with a certificate of value whose validity cannot be disputed" I think this quotation gives the keynote of the book It leads on to discussions of "Body and Soul", "Individual and Society", "Nature and Supernature", "Man Fallen and Man in Christ", all of which are characterized by shrewd insights and an uncompromising adherence to traditional Christian doctrine A particularly interesting and important point is elaborated in the chapter on "Nature and Supernature", where Dr Mascall develops the conception of "the fundamental openness of man s being to God's activity" as the basis of "the Catholic doctrine of the elevation of man's nature to the level of supernature by grace"

Much in this book will seem to scientific humanists strange and unacceptable, but they may learn something from it and in any event there is æsthetic pleasure in reading a thesis clearly stated and ably argued W R MATTHEWS

T. H. HUXLEY

T H. Huxley
Scientist, Humanist and Educator By Dr Cyril Bibby Pp xxii+330+13 plates (London C A Watts and Co , Ltd , 1959) 25*s* net

TOO many people remember T H Huxley simply as 'Darwin's bull-dog' The occasion of dramatic reproof to an ill-mannered and ignorant bishop is a single incident that obscures a life of energy and devotion in many fields , and Dr Bibby's book, painstaking though it is, does not really succeed in communicating the excitement of the intellectual battlefields over which its hero fought Partly this is due to its arrangement The author has discarded a straightforward biographical treatment in favour of one in which separate sections deal with particular aspects of Huxley's interests The result is to dehumanize the central character, to make him less a vivid and warm personality than a mouthpiece for sentiments that leave an impression of worthiness rather than intensity But the cause of this flatness is not primarily Dr Bibby's fault , it is simply that much of what Huxley thought and said is no longer a daring adventure of ideas His reputation has suffered by his own success He appears less exciting to us than he did to his contemporaries because many of the battles which he fought with such vigour have now been won The biological views which he supported are in modified forms part of the accepted fabric of our thought The aim of an adequate provision of scientific education, or indeed of adequate and universal education of any kind, which he spent himself in promoting is now, if not achieved, at any rate acknowledged as a necessity for a civilized community; and at a deeper level the scientific and rational attitude which was the mainspring of his life and work is nominally at least part of the intellectual climate of our time.

But it would be a very superficial view of Huxley that dismissed him as a thinker from whom we have nothing to learn. Huxley was a man who was very characteristic of his time; it can truly be said that he embodied those qualities of the Victorian Age which we can most envy and most admire. It was an age of principles and of beliefs, and Huxley himself believed passionately in the value of human reason, in the power of education to transform societies, and in the power of science to change not only man's environment but also his habits of thought. He was a Victorian of the same mould as Thomas Arnold and George Eliot. To the causes in which he believed he sacrificed his own scientific achievement, and it is an interesting speculation as one reads this book to ask whether or not Huxley was right to leave undone the original work he might have carried out in the laboratory and instead spend endless hours in committees, on the London School Board or in writing controversial articles. For him education, science and greater social equality were causes to be fought for with incredible industry, with the resources of a superb gift of writing, and with a pervading moral earnestness. If one adds to these no little ability in the art of wire-pulling for good causes one can understand why he attained an influence over the thought of his time that few men have had.

By comparison our own age seems half-hearted and disillusioned. Two great wars have shown us that a civilization highly developed in science and technology is still capable of behaving as irrationally and cruelly as a band of savages. One of Huxley's own gifted grandsons has revealed the kind of Utopia to which scientific progress can conceivably lead. We have lost the certainties and the simplicities of the Victorians, and it would no longer seem worth while for an eminent man of science to conduct a controversy with a prime minister on the credibility of the story of the Gadarene swine. The irrationalities of our time are more pervasive and infinitely more harmful than those against which Huxley fought. But if Huxley's beliefs seem in some ways over-simple, his vigour, his humanity, his belief that the scientist must show concern for the social and intellectual problems of his time, offer us a great example. Huxley stands as evidence of the fact that a scientist can also be a humanist and an educator, and Dr Bibby deserves our gratitude for making clear this triple contribution at a time when some such synthesis is so necessary.

JAMES OF RUSHOLME

STARS AND MEN

Of Stars and Men

The Human Response to an Expanding Universe. By Harlow Shapley. Pp vii+145. (London: Elek Books, Ltd., 1958.) 15s net.

DR HARLOW SHAPLEY, director of the Harvard College Observatory for more than thirty years, is a world-renowned figure in the fields of astronomy and cosmography. He has the not common gift of being able to write simply and lucidly for both scientist and layman. Dr Shapley begins by attempting an obituary of the anthropocentric view that man is the centre of the cosmos, and continues by interpreting the consequences to man (or rather to certain aspects of rational thinking) of the latest scientific discoveries in the cosmos. Dr Shapley's interpretation of man's position in the cosmos—a favourite theme since the writing of the first chapter of Genesis—is the latest and the best to date, but it will not prove to be the last. No doubt Dr Shapley deduces from our cosmological knowledge the best interpretation of our present generalizations, but only from the physical point of view. It is difficult to know how terrestrial man can ever do more than speculate on the existence of life on planets outside his own solar system. Interesting as all this is as a rational and speculative exercise, much of the issue is evaded. The nature of man as a spiritual being capable of high aspirations, of self-sacrifice, and the creation and appreciation of beautiful things, does not appear in Dr Shapley's picture to any great extent. This is not to belittle this book; within the framework which he honestly sets out at the beginning he has developed his story with logic, restraint and charm, but few people will think that it is the whole story.

Dr Shapley's displacement of human life from its once supreme position does not make him a pessimist, for he argues cogently that there must be at least a hundred million planets capable of supporting some form of life. Dr Shapley concludes his book with what he calls "a Martian look" into the future. He dismisses the prospect of the Earth's collision with a star, or of wandering from its orbit and getting too near or too far away from the Sun. Nor does he envisage a biological calamity wiping out the whole human race. The real danger is man himself, who is busy perfecting the tools for performing an operation which is unlikely to be performed by natural forces.

"Fish or *Homo*, that is the question. Which animal type will most certainly be here 10,000 years from now, and which will more likely fall the victim of fate and folly? The answer, of course, is too obvious. The fish have been here several hundred million years; man but a few thousand. ... But 10,000 years is a pretty long time for *Homo*. His structure and social manners do not make him a good insurance risk."

Much humanism is a weariness of the flesh and in the making of cosmologies there is no end, but Dr. Shapley avoids these pitfalls and has written a book which should stimulate and challenge every intelligent reader.

W. L. SUMNER

ASTROPHYSICS

Handbuch der Physik

Herausgegeben von S. Flügge. Band 50: Astrophysik 1: Sternoberflächen-Doppelsterne. Pp vii+458. (Berlin: Springer-Verlag, 1958.) 98 D.M.

THIS is the first of the five volumes of the new "Handbuch der Physik" which are to be devoted to astrophysics. Preliminary announcements show that a wide range of subjects is to be covered, excluding solar physics but including some of the most recent developments in other fields. However, the contributions in this particular volume deal mostly with the older parts of astrophysics, based on techniques well established before 1940 But they are none the worse for that, indeed, it is one of the weaknesses of present-day astrophysics that insufficient effort is being put into basic measurements such as are dealt with in several of these articles, for example, stellar masses and radii from visual and eclipsing binaries, atomic abundances from stellar spectra

Ch Fehrenbach has given a full account of the classification of normal stellar spectra P C Keenan has written briefly of stars with peculiar spectra, in a useful although not comprehensive article which contains material not readily obtainable elsewhere, for example, on high-velocity stars P. Swings's contribution on molecular bands in stellar spectra deals with a complicated subject in which much remains to be done and in which there is a scarcity of other publications Two useful contributions by K Wurm on planetary nebulae are widely separated in the book, although intended to complement each other I find it difficult to understand why they were not united J L Greenstein has written an important original paper on white dwarf spectra which is essential reading for anyone working in this field

P van de Kamp's article on visual binaries is to be commended It deals with a woefully neglected subject on which there is no modern text-book There follow accounts of eclipsing binaries by S Gaposchkin and of spectroscopic binaries by O Struve and Su-Shu Huang Eclipsing binaries are usually also spectroscopic binaries, both classes are very important sources of data for checking theoretical models, but the complications shown by their light curves and spectra have led to speculative ideas for which we have as yet no adequate check

The article by D Barbier is virtually a short text-book, giving a good systematic exposition of what may be called the conventional theory of stellar atmospheres and its very solid achievements

The articles are in English, French or German Each includes a brief general bibliography, in some cases with short comments Adequate attention has been given to other references also The index is in three parts German with an English translation, English with a German translation, and French only for the three articles written in French

As in every "Handbuch" of this character, the contributions vary a great deal in merit, the better ones are excellent Present indications are that this is to be one of the cheaper volumes, although its price is more than £8 R O Redman

ELECTRONICS IN BIOLOGY

Electronic Apparatus for Biological Research

By P E K Donaldson With contributions by Dr J W L Beament, F W Campbell, Dr D W Kennard, Dr R D Keynes, Dr K E Machin and Dr I A Silver Pp xii+718 (London Butterworths Scientific Publications, New York Academic Press, Inc, 1958) 120s, 20 dollars

To be able to use and interpret correctly the results obtained by using electronic apparatus, the biologist requires some understanding of electronics—a secondary subject which may have little direct appeal to him—and for this reason, a book explaining concisely the principles and functions of electronic apparatus used in biological research could be of great value The author of the book has had the needs of the biologist primarily in mind and he and his associate contributors, as members of the staff of the Department of Physiology at Cambridge, ought to be well qualified to look after his needs

The book is divided into four parts Part 1, principles of electronics (277 pp), Part 2, practical use of components (48 pp), Part 3, articles by specialist contributors on transducers, electrodes, indicators and measurement of temperature, light and radioactivity (249 pp), Part 4, complete apparatus (127 pp) The first part is of standard text-book form, with the exclusion of subjects considered to be of little interest to the biologist The treatment is brief, and in some cases, unfortunately, it is insufficient to permit one to follow applications which are given later The section on filters is too detailed for the reader wishing to be acquainted with, rather than fully to understand, the subject On the other hand, the application of the valve as a switching element is covered very briefly, and no mention is made of the pulse response of networks with reference to differentiation and integration The various sources of noise are analysed, this chapter being particularly useful in quoting orders of magnitude The graphs here are excellent and self-explanatory but could have been more conveniently placed in relation to the text, as has been done elsewhere In separating the information on batteries in Part 2 from the section dealing with stabilized power supplies, the opportunity to discuss their relative merits is missed

There are nine chapters in Part 3 dealing with specific subjects, all of which should prove useful to anyone concerned with biological instrumentation The theoretical treatment of light sources and detectors is well done, as also is the assay of radioactivity, but circuit applications would have improved both chapters The articles on electrodes, transducers and the use of relay circuits are valuable contributions, but that on temperature measurement could have been improved by a recapitulation of the physical principles

The important section of Part 4 dealing with apparatus is unfortunately condensed into only one-sixth of the book Stimulus artefact is explained very well, as is also the subject of interference, and all readers interested in design would benefit from the author's design procedure A chapter on transistors gives a useful introduction to the principles, but an assessment of their possible future in biological research would have helped to define their importance

The book is well written, and the practical advice given shows that the author writes from experience Its value could have been increased by linking the biological specifications to appropriate designs, an important feature of biological instrumentation The failure to achieve this linkage makes the book of rather limited value to the engineer who is designing apparatus for biologists However, in helping to satisfy the requirements of the physiologist, the aim of the author has been achieved, albeit at a high price In the preface the author expresses doubts about the suitability of the title, and since the emphasis is so much on physiological applications, the reviewer is of the opinion that "Electronic Apparatus for Physiological Research" would convey more precisely the nature of the subject-matter

W J Perkins

HISTORY OF TECHNOLOGY

A History of Technology
Edited by Charles Singer, E J. Holmyard, A R Hall and Trevor I Williams Assisted by Y Peel, J R Petty and M Reeve Vol 5 The Late Nineteenth Century, *c* 1850 to *c* 1900 Pp xxxviii + 888 + 44 plates (Oxford Clarendon Press, London Oxford University Press, 1958) 168*s*. net

THIS fifth volume of the "History of Technology", covering the approximate period 1850–1900, marks the conclusion of this great work, which traces the development of technology from the earliest times to the beginning of the present century In some fields brief reference is made in the present volume to developments that have taken place so recently as the years following the Second World War

The book is divided into eight parts The first deals with primary production, including the management of food and the development of the metal and petroleum industries The second part concerns itself with stationary and marine steam engines and the internal combustion engine Part 3 treats of the rise of the electrical industry , Part 4 of the chemical industry Part 5 deals with transport, including railways, ships, aircraft, road vehicles, and cartography and other aids to navigation Part 6 is concerned with civil engineering, and covers building materials, bridges, tunnels, hydraulic engineering and water supplies The seventh part discusses manufacturing in general, including textiles, metals, machine tools, ceramics, glass, printing, photography, and rubber The last part evaluates technological education and the general role of technology and its social consequences in the modern world

Each of the chapters is written by a competent authority, and the whole volume has been brought together and made into a unified work by its principal editor, the eminent Dr Charles Singer, and by Dr E J Holmyard and two other distinguished co-editors

Although it could not be expected that every one of the thirty-four chapters would delve with equal thoroughness into the mass of technological history behind each subject treated, nevertheless, the whole presents a most enlightening and valuable summary of progress during the crucial last half of the nineteenth century For example, two such different stories as the development of machines for the generation of electricity and the discovery of aniline dyes are almost breath-taking in their implications for later pure science as well as for technology

It is certain that many full reviews of this extensive and admirable work will be written in Great Britain The present American reviewer feels that he should devote special attention to the volume as it may appear to some American eyes First of all, it is impossible not to be struck by the clarity of exposition of the present work It is hard to believe that an equal number of American students in this field could be found who could write so well It is indeed surprising to find authorities in the highly specialized fields of technology who are able to present their subjects so lucidly The style of the volume will make it attractive even to the layman who is concerned with the full history of our age Anyone who is interested in reading present-day political or social history will also enjoy the style and the content of this volume Here the reader is not overwhelmed by mathematics or repelled by an unnecessarily technical vocabulary It has been possible for the editors to cover the really vast human achievement that is considered in this book only by exercising great verbal restraint Often a single sentence summarizes a large development that even in an encyclopædia article might have been given a long paragraph For example, Josiah Willard Gibbs, considered by some to be the man who did most for pure science underlying technology in America during this period, is described in four words as the formulator of the phase rule

I could not indeed read many pages of this book without thinking of the fascinating problem of national differences in the approach to scientific and technological history In recent years the world has noted successive Russian claims that very many of the great inventions and developments of the past really originated in Russia Similarly, one who walks through the Deutsches Museum in Munich must feel that the tens of thousands of earnest young Germans who go through its admirable halls each year must gain the impression that the full flowering of the industrial revolution took place almost alone in fertile German soil It is similarly apparent that the present volume quite properly emphasizes British science, technological inventions and developments This very fact makes the work especially valuable in America Many new industrial developments in the United States grew out of British beginnings, and this volume clearly portrays this essential background

Some day a general treatise on detailed technological developments in the United States will be prepared, and when it does appear, it will be a valuable supplement to the present volume When such a treatise is written, it will, for example, give full emphasis to the material contained in the voluminous publications of such organizations as Benjamin Franklin's still very active, learned academy, "The American Philosophical Society, Held at Philadelphia for the Promotion of Useful Knowledge" , the National Academy of Sciences of the United States , and the Smithsonian Institution It is indeed a little surprising to find no reference in the index to these American organizations, which were doing so much for world science and technology during this period, in spite of many references to the Royal Society, Royal Institution, and the Science Museum, South Kensington It is quite understandable, however, that the mass of American material could not be dealt with in a complete way in the present book, which is very properly British in its central emphasis

All five volumes of this great work, nevertheless, fill a need long and keenly recognized, especially, it may be, on the western side of the Atlantic Americans will long be deeply conscious, therefore, of the debt that they owe to the distinguished authors and editors of all five volumes of the work The book will be read with pleasure and satisfaction by everyone in the United States who is professionally concerned with the history of technology and, as already suggested, by many others as well In the years ahead these volumes will be among the reference books most frequently reached for on the working shelf of any student who is concerned with this area of scholarship An expression of gratitude is also due to the great Imperial Chemical Industries, Ltd , which helped to make possible the preparation of these expensive, well-illustrated, and well-printed volumes

LEONARD CARMICHAEL

THE WISTAR INSTITUTE OF ANATOMY AND BIOLOGY, PHILADELPHIA

By Dr R E. BILLINGHAM and Dr H KOPROWSKI (Director)

No institute is more deeply rooted in the history of American biology and medical science than the Wistar Institute of Anatomy and Biology of Philadelphia (Fig 1) Its opening in 1894 was made possible by the generosity of General Isaac J Wistar, a colourful figure in American history—sometime farm-worker, trapper, lawyer, company president and Union Army general Its primary purpose was to house a fine collection of anatomical specimens and preparations in the Hunterian tradition amassed, in part, over the years by General Wistar's great-uncle, Prof Caspar Wistar, doctor of medicine of the University of Edinburgh, professor of anatomy at the University of Pennsylvania, and in 1811 author of "System of Anatomy", the first and for long the standard anatomical text in America. The other distinguished contributor to this collection was Dr W E Horner, who was at one time dissector to Wistar and who later occupied the chair of anatomy

In addition to its museum, the Institute was equipped with laboratories and facilities to enable investigators to study comparative anatomy and experimental biology In 1923, a complete printing press organization was established on the premises so that the Institute could exert more efficient control over the well-known journals and publications bearing its imprint, some dating from 1908 The intensive investigation of the laboratory rat has been almost a Wistar prerogative for nearly half a century, indeed the albino rats from its large animal colony have probably propagated the name of the Wistar Institute throughout the world almost as effectively as its journals

Probably because of the changing emphasis in biological and medical research, the Institute's facilities became no longer adequate to attract those investigators who wished to work in the forefront of biological science, and its scientific contributions declined sadly In 1957, however, the Board of Managers appointed Dr Hilary Koprowski, a virologist, as director In the ensuing months, grants from the Federal Government, private enterprise and personal donations have been spent in modernizing the Institute in all respects and enlarging its scientific staff to its present level of fifty, which includes representatives of seven different nations

According to its statute book "The Institute will be open to any and every searcher for knowledge", and at present it has eight graduate research students who are enrolled at the University of Pennsylvania, which lies immediately across the street and in which several members of the staff hold academic appointments There are Wistar professors of microbiology, of research medicine and of zoology, and some associate and assistant professors Indeed, the loose affiliation between the Institute and the University of Pennsylvania is ideal for both organizations According to its deed of trust "the object of the laboratories and workrooms and of any lectures or instruction to be given at the Institute shall be for the improvement and research of postgraduate or advanced students and of searchers after new and original knowledge, and neither the Institute, its premises or property shall be used to replace or supersede such elementary instruction of undergraduate students as now does, or hereafter may fairly pertain to the ordinary or necessary curriculum of the University"

To commemorate the recent completion of the Institute's re-organization a symposium on "The Structure of Science" was held during April 17–18, and attended by more than five hundred biologists The subject of the first session was "National and International Research" The opening speaker, Mr Francis Boyer, president of Wistar's Board of Managers, stressed the important role still open for small, independent research institutes in contemporary science The Hon Lister Hill, United States Senator from Alabama, gave an account of the Bill which he recently introduced in Congress to create a National Institute of International Medical Research, as part of the National Institutes of Health This would be charged with the support of medical projects submitted by competent investigators from any part of the world Other speakers were Dr Leroy Burney, surgeon general, United States Public Health Service, who emphasized the extremely liberal conditions under which federal grants were made to research institutes such as Wistar, and Dr Detlev Bronk, president of the Rockefeller Institute and the National Academy of Sciences, who spoke of the importance of allowing investigators complete freedom of action in a world that is constantly clamouring for direction of research Finally, Dr Tuzo Wilson, professor of geophysics, University of Toronto, gave an illustrated account of his recent visit to "mainland" China and Formosa He said that the mainland Chinese were the hardest working people he had ever seen If their geophysical laboratories are a measure of their activity in other disciplines, it would not be long before they contributed fully to world science

The following session, subtitled "The Road to Knowledge", was opened by a paper on mathematical principles in biology by Dr Nicolas Rashevsky of the University of Chicago He said that hitherto it was only in genetics that mathematical biology had achieved a definite predictory and explanatory value After outlining the difficulties of attempting to apply or develop theoretical biology to explain organic form or complexity of organization—analytical geometry cannot take into account such a trivial event as a cat changing its posture—he outlined a "principle of optimal design", according to which the overall design is compatible with the highest degree of economy for a given set of physiological functions This concept had already been applied successfully to the design of the vascular system Dr Rashevsky then discussed the relationships between physico-chemical processes underlying super-

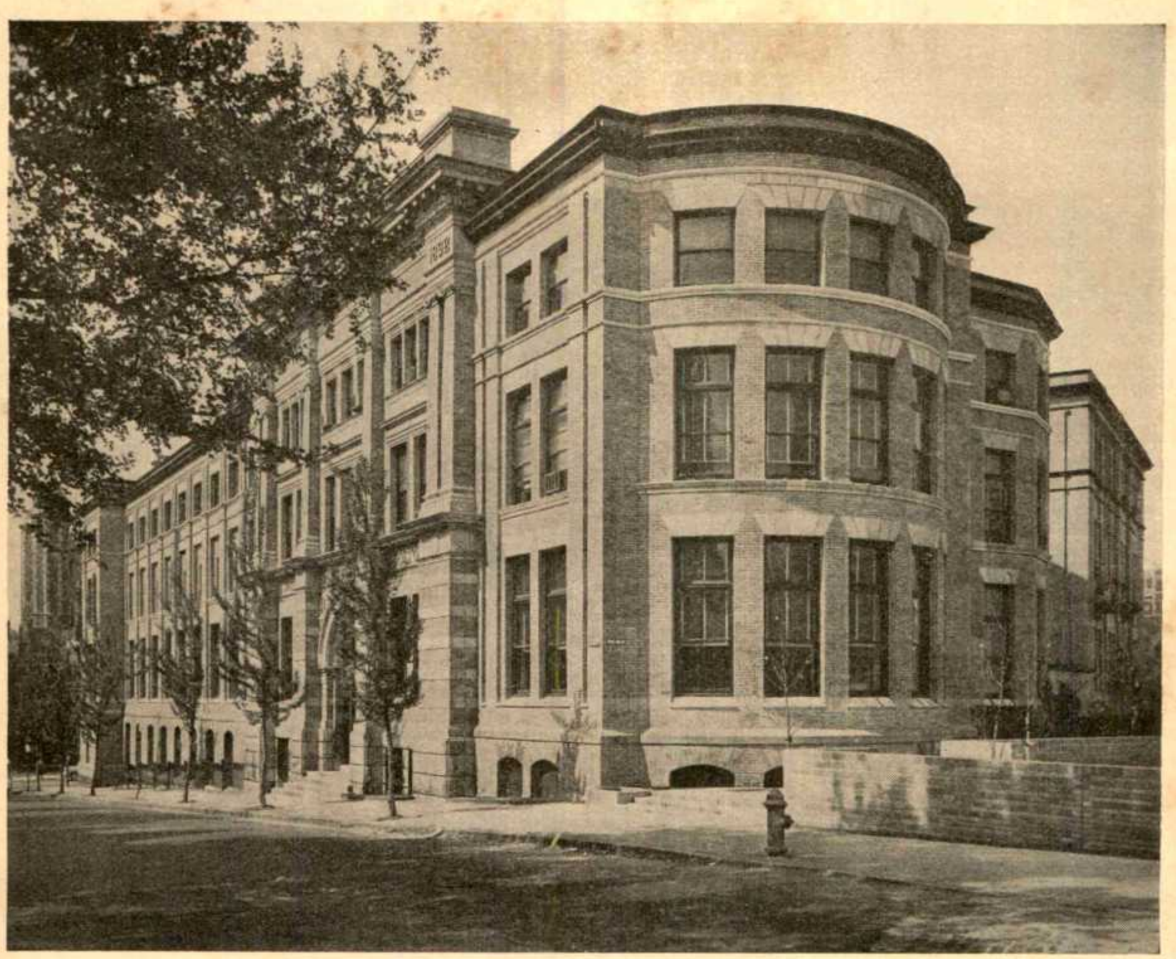

Fig. 1. The Wistar Institute of Anatomy and Biology, Philadelphia. The building, completely renovated in 1958–59, now houses new laboratories and equipment for its staff of fifty scientists

ficially comparable events in higher and lower organisms, and argued that despite their greater repertoire, the biological processes of higher organisms were interpretable in terms of the fewer properties of simpler organisms. He predicted that a unicellular organism will be found capable of producing antibodies to some specific antigens.

Dr. Ludwig von Bertalanffy, Sloan visiting professor at the Menninger Clinic Foundation, discussed the role of theoretical biology in integrative sciences. He stressed the inadequacy of the mechanistic approach derived from classical physics, which had as its goal the resolution of living things into component parts and processes, by analogy with machines. In the new philosophy the organism was no longer to be considered as being simply a reactive system, answering stimuli of extraneous origin in order to re-establish some sort of equilibrium. In Bertalanffy's own words, "the problems of organic wholeness, organization, teleology, and the like, which were taboo in the mechanistic world picture, are now taken seriously and approached as legitimate problems for scientific inquiry and theory".

Dr. Anatol Rapoport, professor of mental health, University of Michigan, in a witty and lucid consideration of the language of science, said that although most advanced branches of science had developed their own special languages, such as the molecular structural symbolism of chemistry, there was still a residue of "ordinary" language—its vernacular component. With particular reference to chemistry and physics, he argued that the language of science neither depended upon an extensive vocabulary nor was necessarily devoid of poetry. Key terms in higher algebra included 'group', 'ideal', 'trace', and fundamental words in physics were likewise simple—for example, 'field', 'orbit', 'nucleus'—yet it was impossible to explain the meaning of any of these words to anyone lacking considerable experience of the appropriate kind. In the language of science, very simple words were used to denote exceedingly complex concepts. Most of the terms in physics were defined by mathematical operations, for example, 'feet per second squared', in contrast to classical terminology which was translatable into visual images. This far-reaching innovation freed the intellect from dependence on literal conceptions and mathematical operations had largely taken their place.

Dr. Rapoport denied that the language of science was prosaic. It has its own metaphors: the 'osculating curve' (not an amatory function, but a mathematical form), the engineer's 'black box', the neurophysiologist's 'threshold', and the mathematician's 'primitive'. In conclusion, he brought up a most profound question of scientific philosophy—the metaphysical underpinnings of the language of science: Where was the borderline between knowledge and faith?

The last speaker of the session, Dr. Donald H. Andrews, B. N. Baker professor of organic chemistry in Johns Hopkins University, discussed new relationships between art and sciences. He developed an interesting idea on the analysis of form in terms of thermodynamics and entropy on one hand, and of information theory on the other. Citing as an example an unstruck piano string vibrating with overtones set up by its thermal energy, Dr. Andrews argued that a statue of marble probably had overtones "which in the harmonic realm are the exact equivalent, homomorphic with the space form". If this statue were cooled to within perhaps a 200,000th of a degree of absolute zero and its heat capacity measured and integrated as it was warmed very slowly, the entropy term would be obtained over the very lowest part of the temperature-range and would bear a direct relationship to the shape of the statue, based on the longest thermal vibrations, with wave-length a function of the shape of the statue.

In theory it should be possible to transmit 'space-form' information defining the statue over a distance via radio waves or telephone signals for reproduction at an appropriate lathe-assembly. Developing such new concepts of 'scientific æsthetics', Dr. Andrews concluded that perhaps a more faithful algebra of form was needed for many of to-day's problems, in thermodynamics, in the study of molecules and of molecular aggregates.

The speakers at the third session of the symposium concerned themselves with unifying principles in their respective fields.

Prof. P. B. Medawar, professor of zoology, University College, London, presented a critical account of the various possible theories which might account for the phenomenon of immunological tolerance—the specific immunological unresponsiveness induced by exposure of very young animals to antigens. After making two assumptions : (1) that the maintenance of the tolerant state depends on persistence of the antigen, and (2) that any one antibody-forming cell (and its descendant clone) responds to only one antigen at a time, he considered, in turn, a series of mutually exclusive postulates, for example, that immature antibody-forming cells capable of being made tolerant occurred (*a*) only in embryos or very young animals, or (*b*) in adults as well. He then went on to discuss the hypotheses one could arrive at by various combinations of postulates, one of which led logically to the view that while some cells in the adult became immunized by exposure to antigen, others must become tolerant.

Dr. Francis H. C. Crick, Cavendish Laboratory, University of Cambridge, spoke on the structure of viruses. He emphasized the multiplicity of factors which govern the aggregation or packing of identical units into a given space. In the simplest case, spherical sub-units are aggregated so as to occupy the smallest possible space. Such an array has certain elements of cubic symmetry. There are five-fold, three-fold and two-fold axes of symmetry. The surfaces of many viruses are polygonal with elements of 2-3, 4-3-2 and 5-3-2 symmetry ; in some of these evidence has been obtained of a regular array of sub-units. Apparently, the protein parts of many viruses are made up of roughly spherical sub-units assembled in such a manner as to occupy the least space.

Studies on infectious ribonucleic acid isolated from tobacco mosaic and certain mammalian viruses indicate, according to Dr. Crick, that the ribonucleic acid carries, at least in part, the necessary information to determine the amino-acid sequence of the protein sheath of the virus particle. However, since there are no known viruses consisting of less than 70 per cent protein, it is unlikely that the viral nucleic acid carries sufficient genetic information to determine such a large protein shell. The alternative is a large number of small, symmetrically packed, protein sub-units.

Dr. H. Gobind Khorana, University of British Columbia, showed how advances in our knowledge of organic chemical structures and of organic synthesis had contributed to an understanding of biological processes. He reviewed some of the important accomplishments in protein and peptide chemistry—such as the elucidation of the structure of gramicidin *S* and of oxytocic hormones. The determination of the total sequence of structural units in adrenocorticotrophic hormones and other biologically active materials should soon extend to the sequence in larger molecules such as ribonucleases.

Turning to research on intermediary metabolism, Dr. Khorana discussed the organic chemistry of phosphate esters, with particular emphasis on nucleotide co-enzymes, mentioning his own important work on the synthesis of co-enzyme *A*. He said that despite the underlying similarity in the structure of nucleotide co-enzymes, it was at present inexplicable and rather exciting that their specificity depends upon the nucleosides that they carry.

On another topic, the sequential analysis of nucleic acids, he emphasized the present need for research. He described the chemical synthesis of a number of oligonucleotides that would be useful in developing enzymatic degradation methods for structural analysis of nucleic acids. One problem which confronted us to-day, he concluded, was to match the sequential analyses of nucleic acids with similar analyses of amino-acids in proteins and polypeptides.

A lucid discussion of the mechanism of gene-action was presented by Dr. John R. Preer, University of Pennsylvania. He said that genes act by influencing the properties of proteins, probably because they are the determinant forms of the templates (usually held to be of ribonucleic acid nature) which direct protein synthesis. He felt that the original Beadle hypothesis of one gene : one enzyme should be extended to include protein and template, so that one would have one gene : one template : one protein.

The many different strain-specific ciliary proteins of *Paramecium* are particularly advantageous materials for the study of gene-protein relations. Many different loci with multiple alleles are involved in the determination of these proteins. Genes at only a single locus affect each type of protein, and a locus determining one type of protein is without effect on any other locus. This complex situation is explicable on the template hypothesis. Studies on the genetic determination of different types of hæmoglobin in man, which usually differ with respect to a single amino-acid, had furnished beautiful support for gene-amino-acid determination.

Dr. George Klein, Karolinska Institutet, Stockholm, gave a lucid analysis of the evolution of tumour cell populations. The change from a normal to a malignant cell was usually the result of a series of successive qualitative steps, known as tumour progression. The various unit characteristics of tumours such as growth-rate, sensitivity to drugs, invasiveness, etc., did not all change together during progression, but re-assorted independently so that each tumour appeared to undergo an evolution of its own, differing from other tumours on a combinatorial basis. The postulated unit characters were probably not interrelated, but were determined by different cellular mechanisms.

Dr. Klein discussed three of the many conceivable mechanisms which might account for progression: (1) the selection, by intrinsic or extrinsic factors, of new variant cell types differing from the original type with respect to one or more unit characters; (2) the loss of ability of cells to respond to homœostatic forces of the organism; and (3) automatic changes in cell population characteristics which might occur merely by virtue of an increase in the population and did not depend on cellular change. Like Lederberg, he felt that analysis of the mechanisms of progression should be modelled on techniques derived from microbial genetics.

The closing session of the symposium was devoted to papers presented by members of the scientific staff of the Wistar Institute.

Dr. Hilary Koprowski, director of the Institute, spoke of the staff as a group of independent thinkers of widely different backgrounds who approached their scientific problems in individualistic ways but worked together through an "intercommunicating system". The main object of research at the Wistar Institute, he said, was the study of cellular biology, or perhaps more accurately, "the study of the biological micro- and macro-cosmos and the attempt to bridge the gap between the two". He enlarged on this concept, saying that staff members were making quantitative studies at the cellular level and were attempting the difficult and hazardous task of applying knowledge about the cell to studies of the whole organism.

Dr. Angus F. Graham discussed general aspects of cell-virus relationships and the methodology of their analyses. He had been developing an *in vitro* virus-mammalian cell system in fluid suspension, by means of which it might be possible to investigate quantitative aspects of virus infection in a manner analogous to studies with the classic phage-bacteria system.

Dr. Eberhard Wecker presented evidence that the infectious ribonucleic acid which he extracted by the usual phenol technique at 4° C. from cells infected by eastern equine encephalomyelitis or western equine encephalomyelitis was not derived from the virus elementary bodies themselves but from a virus precursor which appeared in the infected cells before the mature virus particles. Although lipid-containing mature virus particles did not yield infectious ribonucleic acid on treatment with phenol at 4° C., Dr. Wecker reported a successful extraction at higher temperatures (40–50° C.). He concluded by indicating how ability to distinguish between the precursor of ribonucleic acid and the acid itself from mature virus particles might lead to a better understanding of the biosynthesis of viruses within cells.

Continuing the discussion of viral nucleic acids, Dr. John S. Colter outlined studies made in collaboration with Dr. Kay Ellem. By a modification of the classic Gierer and Schramm phenol extraction technique for ribonucleic acid, in which cells were disrupted in solutions of high instead of physiological ionic strength, the deoxyribonucleic acid was extracted in the aqueous phase, while the bulk of the ribonucleic acid was eliminated into the phenol phase. The final product was free from protein and ribonucleic acid, and the yield was quantitative.

By adding sodium desoxycholate, the recovery of infectious ribonucleic acid by Gierer and Schramm's phenol extraction method from Ehrlich ascites cells infected with Mengo or West Nile viruses was greatly improved—possibly even five-fold. A collateral study of the ribonucleases of normal and malignant murine tissues implicated the pancreas as the source of the enzyme. Because of the existence of a ribonuclease inhibitor the pattern of ribonuclease activity of ascites tumour cells differed markedly from that of a normal tissue. The possible role of the magnesium ion as an inactivator of ribonuclease activity was discussed.

Dr. Raymond A. Brown outlined the biophysical properties of the preparations of deoxyribonucleic acid isolated by Dr. Colter's new method. The molecular weight was four to five million, and its sedimentation constant and intrinsic viscosity values were lower than those usually quoted for deoxyribonucleic acid.

His own electron microscope studies led Dr. Brown to consider cellular ribonucleic acid to be made up of two types of molecules, both 42–43 A. in diameter but differing in length. There was suggestive evidence of a periodicity in the location of the phosphate groups along the axis of the rod. Each rod probably consisted of a tightly coiled single polynucleotide chain. At low ionic strength, the molecule uncoiled.

Dr. Vittorio Defendi discussed the virus-host cell relationships of two tumour-inducing viruses: the *RPL*-12 virus of the lymphomatosis tumour of chickens and the polyoma virus in hamsters. He described the necrotic and proliferative lesions of *RPL*-12 virus infection in tissue cultures, in chick embryos and in hatched chicks, emphasizing particularly the derangement of deoxyribonucleic acid metabolism which occurred during the infection.

He then outlined his findings on the pathogenesis of tumours arising in Syrian hamsters following their inoculation at birth with polyoma (parotid gland) virus. All the tumours were of identical histological type regardless of their location. Preliminary analysis of the infectability of newborn hamsters with the virus suggested that immunological tolerance is involved. For example, inoculation of newborn animals with the virus along with isologous adult lymphoid cells resulted in a greatly decreased proportion of tumour-bearing hamsters, and there was an amelioration of the course of the malignant disease in the minority of animals in which tumours did appear.

Drs. Rupert E. Billingham and Willys K. Silvers described their studies on the tissue transplantation antigen determined by a locus on the *Y* chromosome in male mice. This antigen was responsible for the rejection of male skin isografts by females in many inbred strains. Female mice of the *C*57 strain could be made tolerant of subsequent male isografts by inoculation with male cells as late as 17 days after birth, and tolerance in females could also be induced by means of cell-free antigenic extracts prepared from isogenic male tissues. Employing the principle of immunological tolerance they were able to show that all male mice, irrespective of their genetic constitution, possessed exactly the same *Y* chromosome antigen. This conclusion followed from the finding that *C*57 females injected at birth with cells from males of any other strain are invariably made tolerant of male skin isografts. A *Y*-chromosome antigen was also present in male rats, which preliminary results indicated was exactly the same as in the mouse.

Concluding the symposium, Prof. Sven Gard, Karolinska Institutet, Stockholm, and visiting member of the Wistar Institute (1958–59), gave warning against the general tendency to over-estimate the potentialities of pure biochemistry The activities of a living cell as seen under the microscope immediately dispelled any idea that it might be regarded as a bag of enzymes The fine structure of the cell with its innumerable surfaces and membranes offered a clue to the fundamental question: "Why and how do reactions occur in the right place at the right time?" The multiplicity of interests disclosed by the staff members of the Wistar Institute, and its strong tradition for morphology should guarantee concentric attacks on essential biological problems

THE AUSTRALIAN ACADEMY OF SCIENCE

On May 6, the Governor-General of Australia, Field-Marshal Sir William Slim, opened the new building which houses the offices and conference chamber of the Australian Academy of Science The establishment of the Academy was initiated by a group of Fellows of the Royal Society of London resident in Australia (*Nature*, 170, 549, 1952) With the help of other Australian scientific leaders, they set up a body which received a Royal Charter personally from Her Majesty Queen Elizabeth II during her Australian tour in 1954

The Australian Academy of Science is the representative body of Australian scientists at the national level, with functions comparable with those of the Royal Society of London, which was itself represented at the opening, on May 6, by its senior vice-president, Sir Lindor Brown The fellowship of the Academy now numbers eighty-seven and up to six new Fellows are elected each year The president of the Academy since 1957 has been Sir John Eccles, professor of physiology in the Australian National University, Canberra, his predecessor was Sir Mark Oliphant, director of the Research School of Physics in the National University

In outlining the history of the Academy, Sir John Eccles said that the need for a national scientific body of the highest standing led in 1919 to the formation of the Australian National Research Council, and thanks to the devoted efforts of its leaders, the Council gave most valuable service to Australia Yet it would be generally agreed that it had failed to achieve the status that was required of a national body with such weighty responsibilities Various efforts at internal reforms of the Council proved to be impracticable and a more radical proposal emerged from a conference on "Science in Australia" organized by the Australian National University in 1951 At this conference and in the subsequent discussions there was a fairly general agreement that an Academy of Science with much more restricted membership should replace the National Research Council The Council's executive with great magnanimity agreed to its dissolution in order to make way for the new Academy This was a fine act of self-sacrifice made in the belief that the new Academy would be better fitted to give leadership in the scientific development of Australia

The new Academy chose to model itself closely on the Royal Society of London, so taking advantage of three centuries of wisdom The Academy is also especially indebted to the Royal Society for help in its petitioning for the Royal Charter, and for the gift of a magnificent Signature Book that is a replica of the original Signature Book of the Royal Society

From the very beginning it has been of prime importance to ensure that the highest standards were maintained in the election to the fellowship, and that it was truly representative of all aspects of pure and applied science It could be claimed that it has retained the confidence of the general body of scientists in Australia

The functions of the Academy are both national and international At the national level there are certain general responsibilities in the fostering of science and in its publication However, it is at the international level that the Academy has its principal opportunities and functions First, it is the body representing Australia at all the international scientific unions as well as at the Pacific Science Congress and the Pan Indian Ocean Congress Secondly, it undertakes international scientific tasks for Australia The most notable has been the International Geophysical Year, the Academy being responsible for Australia's fine contribution From the International Geophysical Year there have developed further important international activities in which again the Academy represents Australia The Special Committee for Antarctic Research and the Committee for Space Research are of vital interest to Australia, and both have achieved a high status The third meeting of the Special Committee for Antarctic Research was held in Canberra this year and was generally agreed to be very successful Among other achievements was the inauguration of the International Antarctic Analysis Centre as an annex to the Bureau of Meteorology in Melbourne Other international activities are the organization of specialist international scientific meetings in Australia In August a specialist biochemical meeting on hæmatin enzymes was held at the Academy It is a field in which Australia holds a high place, and many of the leaders in other countries went to Australia for the conference Next year the Academy is arranging for an international conference on the chemistry of natural products, which will be held in Melbourne, Sydney and Canberra

In all these national and international activities the Academy can count on the devoted service not only of its own fellowship but also of the other scientists of Australia The aim is to select the scientists best fitted for these special purposes regardless of their affiliation with the Academy On the Standing and National Committees of the Academy the Fellows are outnumbered, and often scientists who are not Fellows hold key positions

There will be no relaxation of labour now that a centre for science has been established in Australia It has fine symbolism with its geometrical form and its great restraint of line and décor The Academy can now and in the future radiate its influence over Australia and the world and receive from the world for Australia But every end is a new beginning, and the Academy is now planning to become as well a channel for benefactions for scientific purposes and so to exert its influence not only through expert committees and individually by its Fellows but also

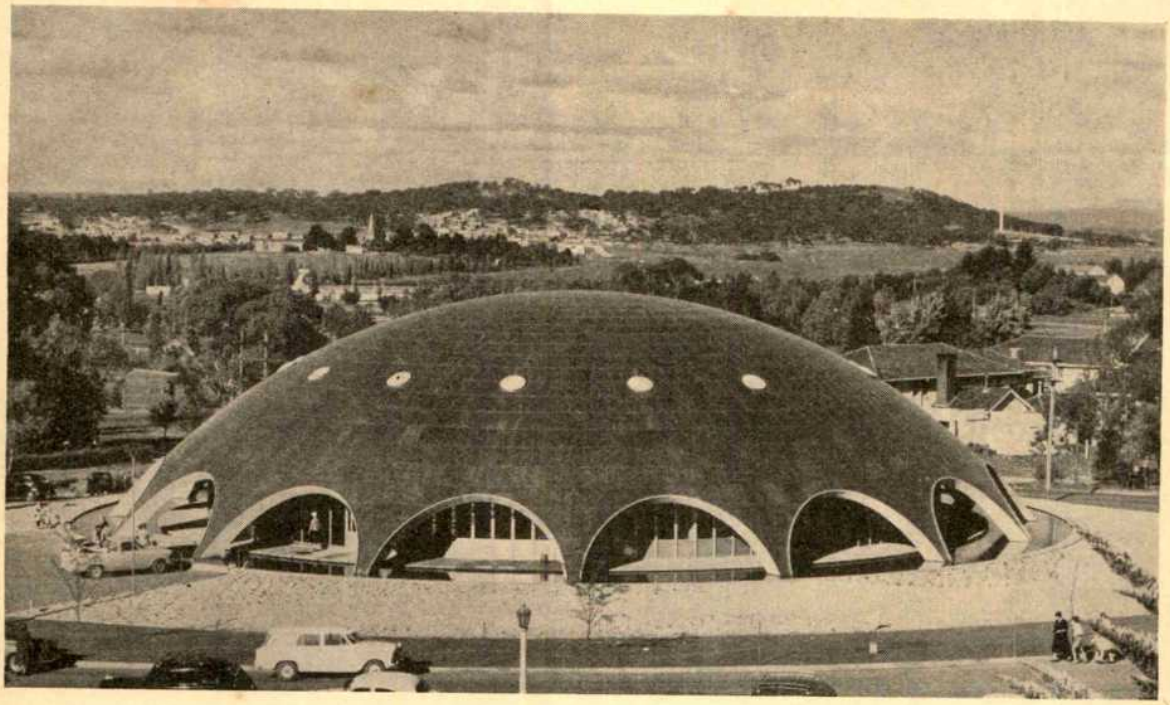

Fig. 1. New Building of the Australian Academy of Science, in Gordon Street, Canberra

by providing the finance for research projects. Benefactors would be secure in the knowledge that their contributions were being administered by the collective scientific wisdom of the Academy, rather than by the authority of any one scientist, however eminent.

The copper-sheathed dome of the new Academy building (Fig. 1), rising from the waters of a surrounding moat, is backed by the rolling bronze-green hills of Australia's national capital, Canberra. Beneath the dome is a central conference chamber, with luxurious seating for 190 and comfortable seating for a further 100, and a ring of offices, council room, and a superb reception room which overlooks an expanse which will within a few years be part of the central lake-system of Canberra. The conference chamber will be the venue of the annual meetings of the Academy itself, and will be extensively used for meetings of Australian scientific and professional societies, as well as for such international symposia as may be held in Australia.

The national responsibilities of the Academy receive material recognition from the Commonwealth Government in the form of an annual grant towards current expenses. The Academy, however, remains autonomous, and indeed the value of its services is derived very largely from its autonomy. It is too young a body to have achieved financial self-sufficiency through endowments; but the erection of the conference chamber and offices has been made possible entirely because of generous contributions to the Academy building fund by Australia's great industrial firms. To these firms, to the architects, and to the vision and energy of the members of its early Councils, the Australian Academy of Science, and Australia, owe a debt of gratitude; for they have created one of the most striking and important structures in Canberra, and they have provided the Academy with a home of its own which is modern, dignified, and of the highest quality.

MERLIN; AN INDUSTRIAL RESEARCH REACTOR

By Dr. T. E. ALLIBONE, F.R.S.

Research Laboratory, Associated Electrical Industries, Ltd., Aldermaston Court, Berkshire

THE *Merlin* research reactor is situated at the Research Laboratory of Associated Electrical Industries, Ltd., at Aldermaston Court in Berkshire. It was made critical for the first time on July 16, 1959.

The decision to install a reactor for fundamental research at Aldermaston was taken in 1955 and the Associated Electrical Industries–John Thompson Nuclear Energy Co. undertook to supply it. The nuclear physics aspects of the reactor and the design of the control system have been the responsibility of the Associated Electrical Industries Research Laboratory; the mechanical engineering design, the erection and the commissioning of the equipment up to the stage of loading fuel into the reactor have been the responsibility of Associated Electrical Industries–John Thompson. Loading of fuel began on July 6 by the staff of the Laboratory, who are now engaged on the proving trials of the reactor. These trials, which involve thermal, mechanical, electrical and physical measurements, will extend into 1960, while the reactor power is gradually increased to a maximum of 5 MW.

The original design of the reactor was for a maximum thermal power of 1 MW. However, the shortage of test facilities in research reactors in the United Kingdom was impressed upon Associated Electrical Industries, Ltd., by the Atomic Energy Authority, and inquiries from overseas indicated that a 5 MW. reactor was a more likely export, so the design was altered to achieve a power of 5 MW. type which is characterized by a large maximum fast *Merlin* is of the light-water-cooled and moderated (> 1 MeV.) neutron flux per unit of power. The maximum unperturbed fast flux with 3·4 kgm. of uranium-235 in the core is 6×10^{13}/cm.^{2}/s.; the average fast flux in the nuclear power reactors being built for the Central Electricity Generating Board is about 10^{12}/cm.^{2}/s. Because it is the fast neutrons which contribute a large portion of any irradiation damage to materials in a reactor, it should be possible to carry out life tests on materials subject to radiation in power reactors. It is believed, therefore, that *Merlin* will be a very useful addition to the research and testing reactors in the United Kingdom.

A view of the reactor as seen from the experimental floor is shown in Fig. 1. The reactor has been described in detail elsewhere[1]; it is of the pool type, using fuel highly enriched in uranium-235 suspended in a tank of light water. The minimum cold, unpoisoned critical mass of the reactor has been shown in subcritical experiments to be about 2·6 kgm. of uranium-235[2], from which the mass of uranium-235 required to provide a reactivity of 0·055 is calculated to be about 3·4 kgm. With a beryllia reflector, 3 in. thick, added around the vertical sides of the core the corresponding masses of uranium-235 are estimated to be 2·18 kgm. and 2·87 kgm., respectively. The maximum reactivity of the core has been limited to 0·055 for safety reasons. The maximum unperturbed thermal neutron flux with 3·4 kgm. of uranium-235 in the core is 5×10^{13}/cm.^{2}/s.; the average thermal flux in the Central Electricity Generating Board power reactors is about 2×10^{13}/cm.^{2}/s.

The reactor is unusual in that the core can be moved vertically to four positions. The top position permits the addition or withdrawal of fuel or experimental apparatus from the core; the moving core structure can be seen in Fig. 1 as it appears from the top floor of the reactor building when the core is in its highest position. At two lower positions the core is in the plane of sets of experimental facilities, which can be seen in Fig. 2. The lowest position is for storage of the core and is so arranged that the possibility of loss of coolant from the tank in this region is negligible.

The area occupied by the reactor and its associated buildings is close to Aldermaston Lake. The large building contains the reactor and the main experimental area, the reactor control room, the fission-product detector and the ventilation plant for the building. Nearer the lake is the primary coolant pump house, the secondary coolant pump house, a

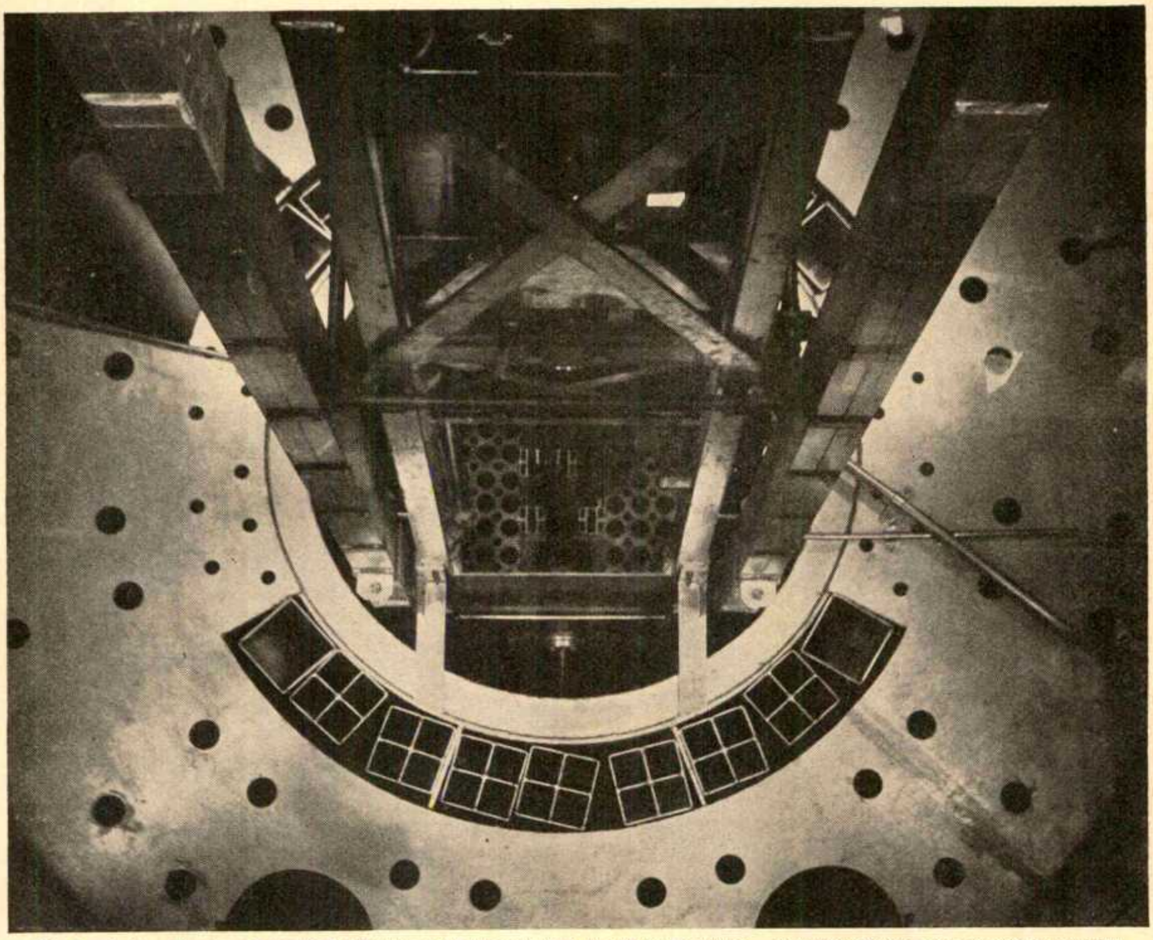

Fig. 1. A view into the reactor tank with the core lattice plate at its highest position. Four fuel elements can be seen in position on the lattice plate. The rectangular containers, in the foreground, are for temporary storage of active fuel elements

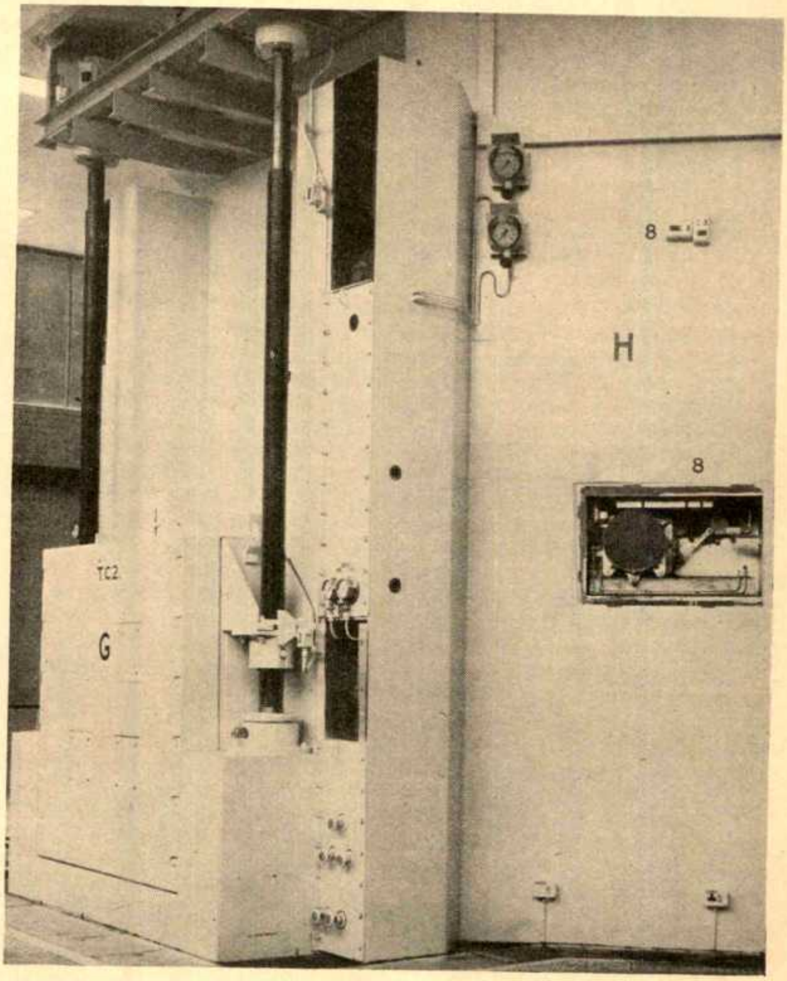

Fig. 2. The reactor and its experimental facilities as seen from the experimental floor

laboratory for sub-critical studies of the reactor core, an effluent plant for processing liquid effluent by filtration and ion-exchange before disposal and a personnel change room for use when entering and leaving the area in which contamination might occur. Four further small laboratories and offices are between the reactor and the lake. Twenty fixed radiation monitors are situated at positions throughout the buildings and in the effluent discharge system, and a further four monitors are situated approximately symmetrically around the reactor, at a distance of several hundred yards, to provide a warning of any undue release of airborne radioactivity.

The proposed research programme for *Merlin* covers both the fundamental and applied aspects of reactor research. Fundamental research being planned includes: the provision of nuclear data, the effects of radiation on materials, a study of Čerenkov radiation in reactors, and methods of measuring neutron spectra. The applied aspects of the research, which will certainly involve some fundamental work also, include: activation analysis, reactor control and safety studies, and the production of short-lived radioactive isotopes.

The Universities of Birmingham, London, Oxford, Reading and Southampton have been invited to consider how they might best use the reactor for the instruction of senior undergraduate and postgraduate students. Members of several university departments and of large polytechnics have spent several weeks with the reactor team, and during this summer a number of postgraduate students from the universities will be working in the laboratory on some research project associated with *Merlin*. University departments have been invited to arrange brief visits to the reactor for final-year students in physics, metallurgy and engineering, and longer visits for postgraduate students.

Dr. A. J. Salmon is the section leader in charge of the project, and the detailed work in the physics, electrical and mechanical engineering of the reactor has been the responsibility of Dr. K. Firth, Mr. B. Millar and Mr. I. Munro, respectively. The Reactor Section, together with the Thermonuclear and Nuclear Physics Section, constitute the Nuclear Sciences Group led by Mr. D. R. Chick, who is also responsible for the overall safety from nuclear hazards. Mr. J. N. Barnett, the Laboratory supervising engineer, has been responsible for the lay-out of this site, with Messrs. Atkins and Partners acting as consultants.

NEWS and VIEWS

Sir Owen Wansbrough-Jones, K.B.E., C.B.

At the end of September, Sir Owen Wansbrough-Jones is resigning from the position of chief scientist to the Minister of Supply. After taking his Ph.D. in the Department of Colloid Science at Cambridge, he spent some time with Hahn in Berlin. He returned to Cambridge both to his old department and to his college, Trinity Hall. There were excellent prospects of a brilliant academic career before him but, just as with his brother, he felt the call to the Army. He succeeded Sir Charles Ellis as scientific adviser to the Army Council. It has been said that the number of civilians who can understand the Army can be counted on the fingers of one hand. Wansbrough was certainly one of them. After some years of close contact with the Army Staff, he realized that he would serve them best by doing his utmost to ensure that the Army gained the weapons that they needed and he consequently moved over to the Ministry of Supply. During Wansbrough-Jones's period of office there has been a notable growth of the scientific spirit in the Minister's establishments. Under his stimulus the research and development work carried out in the Ministry has proved exceptionally fruitful, and is probably better in spite of national economic conditions than anything like it in the world. His colleagues will miss him greatly in his retirement.

The U.S. National Radio Astronomy Observatory : Prof. Otto Struve, For.Mem.R.S.

PROF. OTTO STRUVE has been appointed the first director of the National Radio Astronomy Observatory, Green Bank, West Virginia. The Observatory is being constructed and will be operated by Associated Universities, Inc., under contract to the National Science Foundation. Prof. Struve is at present professor of astronomy in the University of California and has been director of the Leuschner Observatory since 1950. He assumed his duties on July 1. An astronomer of international reputation, he has published approximately a thousand papers concerned with the problems of stellar spectra and other aspects of astrophysics. Although his principal scientific interest has been his important research on the properties of variable stars, his interests have extended more generally over the whole field of astronomy.

The National Radio Astronomy Observatory has been designed to supplement facilities available to research scientists of the universities by making available large and precise radio telescopes not hitherto available to American astronomers. Among these new instruments are the 85-ft. Howard E. Tatel precision radio telescope recently put into operation, the 140-ft. radio telescope now under construction, and a variety of auxiliary devices for radio astronomy. The Observatory is operated by a small permanent staff in co-operation with an increasing number of visiting scientists from various parts of the world.

1964 Olympic Games : Prof. Ryotaro Azuma

THAT the 1964 Olympic Games are to be held in Tokyo is largely due to the efforts of Ryotaro Azuma, formerly professor of pharmacology in the University of Tokyo, who was recently elected governor of Tokyo. Azuma, a distinguished member of the Japanese scientific community, has always encouraged the Olympic ideal of friendship and sportsmanship in international relations. He is a keen sportsman himself—he has rowed for the University of Tokyo; he also introduced the 'shell' to Japan from Britain, where he studied at University College, London, during 1922–24. Azuma is a member of the International Olympic Committee and in 1947 he was asked to head the Japan Athletic Federation. He played an important part in organizing the Asian Games which were held in Tokyo in 1958. Under his leadership sports for enjoyment, as opposed to sports as a form of regimentation, have had an immense success in Japan. Azuma sees a very close connexion between sport and Japan's post-war constitution renouncing militarism; but in his own words: "We must still educate the younger generation that it is not a disgrace to lose if you do your best".

Overseas Research Council

THE Overseas Research Council promised at the Commonwealth Trade and Economic Conference at Montreal last September has now been established. In a statement in the House of Lords, Lord Hailsham said that the Council, of which Dr. R. S. Aitken will be chairman, will provide a central point to which Commonwealth Governments and research institutions can refer for advice and information, and it will advise generally on United Kingdom co-operation in scientific research overseas. There are no geographical restrictions in the Council's terms of reference, and matters concerning scientific development in Colonial territories, in Commonwealth countries and in countries outside the Commonwealth, can equally be referred to it. Moreover, in promoting such development Lord Hailsham said the Council could look to possible collaboration between Great Britain and other Commonwealth countries, countries outside the Commonwealth, such as the United States, and international agencies, such as those of the United Nations and the charitable foundations. Asked whether the members would be paid, Lord Hailsham said he would require notice before replying in detail but he believed certain officers might be paid. There would be a certain amount of travelling and the members of the Council had been selected largely for their knowledge of overseas territories and connexions with science in them.

The other members of the Council are: Sir Jock Campbell, Sir Charles Dodds, Sir Harold Himsworth, Sir Joseph Hutchinson, Dr. R. Lewthwaite, Prof. J. McMichael, Sir Harry Melville, Mr. E. D. W. Nye, Sir Arnold Plant, Sir William Slater, Dr. H. G. Thornton and Sir Solly Zuckerman. The Council will advise the Privy Council Committee on Overseas Research, which consists of the Lord President of the Council and the Secretaries of State for Commonwealth Relations, the Colonies and Foreign Affairs. Its terms of reference comprise advice on the formulation of United Kingdom policy in respect (*a*) of scientific research undertaken in or for overseas territories within or without the Commonwealth, (*b*) of methods of making the results of research available in these territories, and (*c*) of assistance to the scientific services of these territories; on the co-ordination of the activities of United Kingdom Government organizations in the development of science in the civil sphere in overseas territories; and on co-operation within the Commonwealth, with other countries and with international agencies in promoting such development.

National Institute for Research in Nuclear Science

CONTRACTS for more than £430,000 have been placed by the National Institute for Research in Nuclear Science for the manufacture of the magnet coils required to energize the 7,000-ton electromagnet of the 7,000-MeV. proton synchrotron. This machine, which has been named *Nimrod*, is being built for the Institute by the United Kingdom Atomic Energy Authority at the Rutherford High Energy Laboratory, Harwell. Contracts have been awarded to British Copper Refiners, Ltd., of Prescot, Lancs., for the supply of more than 300 tons of refined copper (from which the coils are to be made), in the form of cast billets; to James Booth and Co., Ltd., of Birmingham for extrusion of the cast copper into hollow rectangular bars; and to Metropolitan-Vickers Electrical Co., Ltd., of Manchester, for the manufacture of the finished coils from the extruded bars. The Institute has also awarded a substantial contract to Marston Excelsior, Ltd., of Wolverhampton, for the development and supply of the reinforced plastic vacuum chamber in which the protons are accelerated. This chamber will be one of the largest plastic structures ever made.

Extension to the Chester Beatty Research Institute

On July 16, Sir Chester Beatty laid the foundation stone of an extension to the Chester Beatty Research Institute. The cost of the extension (£200,000), which will double the existing accommodation, is being defrayed from a trust fund deriving from the charitable public, and administered for the benefit of the Institute by the Board of Governors of the Royal Marsden Hospital. A contribution of £40,000 has also been made by the Wellcome Trust, in respect of which the extension will include a Wellcome Laboratory of Pharmacology and Experimental Chemotherapy. The Research Institute of the then Cancer Hospital, established in 1909–10 and opened in 1911 by H.R.H. the Duke of Connaught, was directed successively by the late Dr Alexander Paine, Dr Archibald Leith and Sir Ernest Kennaway. In 1938, Sir Chester Beatty (who was then president of the Hospital) bought, equipped and presented the existing building, which thenceforth became the Chester Beatty Research Institute. The Institute is now part of the Institute of Cancer Research: Royal Cancer Hospital, which in turn is a school of the University of London, and an institute of the British Postgraduate Medical Federation. The Institute obtains its main support from the Medical Research Council and the British Empire Cancer Campaign, and donations and legacies are received from the public. Generous help has also been given by the U.S. Public Health Service and other American sources such as the Jane Coffin Childs Memorial Fund for Medical Research and the Anna Fuller Fund of New Haven, and the Rosenstiel Foundation of New York City. The new building, of which the architects are Messrs Lanchester and Lodge, will be formally opened in 1960, when the Institute celebrates its jubilee year.

First Atomic Merchant Ship

The special illustrated supplement to the June 20 issue of *Atoms for Peace Digest* is devoted to a detailed description of the N.S. *Savannah*, the world's first atomic merchant ship, which was launched by Mrs Eisenhower on July 21, at the New York Shipbuilding Company's Yard in Camden, N.J. The *Savannah*, a joint project of the U.S. Maritime Administration and the Atomic Energy Commission, has been built mainly to promote the peaceful uses of atomic energy and will not be commercially competitive. The vessel is named after the S.S. *Savannah*, the first steam ship to cross the Atlantic, which started her voyage from Savannah, Georgia, to Liverpool on May 22, 1819, and is a combination passenger–cargo vessel, 595 ft long, with a beam of 78 ft. She can carry 9,500 tons of cargo and accommodate 60 passengers, and will be manned by a crew of about 100. Her speed is estimated at 20¼ knots. The *Savannah*'s reactor consists of a system of advanced design using pressurized water as a coolant and moderator, and fuel elements with about 4 per cent uranium-235 enrichment. The active core, which is 66 in. high and 62 in. mean diameter, contains the fissile material—7,050 kgm. of uranium oxide in 32 fuel rods, clad in stainless steel. There is a surrounding pressure vessel, primary shield, containing vessel and secondary shield, of 2,500 tons total gross weight. The reactor will supply 74 MW. of heat, providing sufficient power for the vessel to operate for about three years and to sail 300,000 nautical miles without refuelling. It is being built by Babcock and Wilcox at Lynchburg in Virginia at a cost of about ten million dollars. The total cost of the ship will be about 40 million dollars.

Labour Statistics

The Interdepartmental Committee on Social and Economic Research has recently issued a revised version of its guide to the statistics collected by the Ministry of Labour and National Service (Guides to Official Sources. No. 1, Labour Statistics. H.M. Stationery Office, London, 1959. 5*s*.) The opportunity has been taken to bring the material in the original edition up to date and to include a historical section, showing the development of labour statistics in Britain since the end of the nineteenth century. The topics covered include statistics of employment, unemployment, placings and vacancies, miscellaneous man-power statistics, wage rates, earnings and actual hours worked, strikes and industrial disputes, industrial accidents, the cost of living, retail prices and family budgets. Each of the sections is followed by a comprehensive bibliography of official sources.

World Distribution of Atmospheric Water Vapour Pressure

The Meteorological Office is much more than a forecasting institution. It is the public repository of knowledge regarding the weather, and among its many functions is the provision of data on a world-wide scale for a variety of users. "World Distribution of Atmospheric Water Vapour Pressure", by G. A. Tunnell (Geophysical Memoirs, No. 100. Pp. i+61. M.O. 584*h*. London: H.M. Stationery Office, 1958. 10*s*. net) is an atlas of the distribution over the whole world of the daily mean of atmospheric water vapour pressure for the months January, April, July and October, based on records from 3,500 stations. There follows a brief survey of the world distribution of diurnal variation of vapour pressure in different climates. Information concerning atmospheric humidity in all parts of the world is thus available in compact form for industrialists and others who may require it. Mapping is done by means of isopleths. In common with all such maps, the distributions so revealed have many interesting features not always readily explained. For example, taking account of the characteristics of Russia, is the breadth of the patch of higher vapour pressure shown both in January and July near Kazan real ? The midsummer variations in the mean vapour pressure over South Australia are also noteworthy. An agreeable publication, clearly printed, informative, and stimulating in respect of the distribution shown; the policy of the Meteorological Office in producing such memoirs will be widely welcomed.

The Customs and Religion of the Ch'iang

The Ch'iang inhabit a mountainous region in Szechwan in western China and grow maize as the main crop. They speak a Burmese–Tibetan language and are said to have formerly lived in north-eastern China. For some time past, however, they have been losing their own culture and adopting that of the Chinese, with whom they were earlier in conflict. We have such meagre information on the non-Chinese population of China that almost any report is of value. Mr D. C. Graham (Smithsonian Miscellaneous Collections, 135, No. 1: The Customs and Religion of the Ch'iang. Pp. vii+114+16 plates

Washington, D C Smithsonian Institution, 1958) has collected a considerable amount of material in the course of various expeditions to the area between 1925 and 1948 This he presents in a straightforward manner, and although he has little acquaintance with anthropological literature he does at least lay two ghosts assiduously fostered by another missionary, the Rev Torrance, who had claimed not only that the Ch'iang were monotheists but that they were also descended from one of the far-ranging tribes of ancient Israel On the positive side, scholars will be grateful for the information on religious beliefs and practices, particularly the eye-witness account of the ceremonies in the sacred grove As in many other parts of the world, these rituals provide some inclusive focus for the village as a whole, while the ancestral cult serves a similar function in respect of the constituent descent groups

Australian Mammal Society

At the Australian and New Zealand Association for the Advancement of Science meeting in Adelaide, held during August 1958, it was decided to form an Australian Mammal Society, for the time being restricted to professional workers actively interested in indigenous Australian species Members of the Society are made aware of the work and material requirements of fellow members and the interchange of material between members is encouraged The inaugural meeting of the Society was held in the Department of Zoology, University of Western Australia The following are the foundation members of the Society J H Calaby, F N Ratcliffe (A. C T), Dr A Bolliger, Dr. R G Chittleborough, Prof K W Cleland, W H Dawbin, Dr A G Lyne, B J G Marlow, E Le G Troughton (New South Wales), A E Newsome (Northern Territory), Dr J L Harrison (Queensland), Phyllis Pilton, G B Sharman (South Australia), C W Brazenor, J McNally, J A Thompson (Victoria), Jennifer M Barker, S Barker, C H Tyndale-Biscoe, E H M Ealey, Dr W D L Ride, Dr J W Shield, G M Storr, Prof H Waring (Western Australia) The secretary-treasurer for 1958–59 is Mr S Barker, Department of Zoology, University of Western Australia

Linnean Society of London : Officers

At the anniversary meeting of the Linnean Society of London the following were elected officers for the session 1959–60 *President*, Prof C F A Pantin, *Treasurer*, the Earl of Cranbrook, *Secretaries*, Dr H R Hewer (zoology), Dr C R Metcalfe (botany), Dr John Smart (editorial) Prof L J Audus, the Earl of Cranbrook, Mr A W Exell, and Dr H G Vevers were appointed vice-presidents Mr E J H Corner, Dr G Owen Evans, Mr C C Hentschel, Dr A Melderis and Mr Wm T Stearn were elected new members of council Linnean Gold Medals were presented to Prof H Munro Fox and Prof Carl Skottsberg Prof Jean G Baer was elected a foreign member and Mr Warren R Dawson an Associate *honoris causa*

Ramsay Memorial Fellowships

The Ramsay Memorial Fellowships Trustees have made the following awards of new fellowships in chemistry for 1959–60 a General Fellowship at the University of Aberdeen to Mr P J T Tait, a Canadian Fellowship to Mr W G Paterson at the University of Oxford, a Japanese Fellowship to Mr Toshinobu Anno at the University of Oxford, a Netherlands Fellowship to Dr H C Volger at the University of London (University College), Spanish Fellowships to Dr Felisa Nuñez Cubero at the University of Nottingham, Mr J B Callija at the University of Bristol, Swiss Fellowships to Dr Otto Stamm at the University of London (Imperial College of Science and Technology), Dr Fritz Kneubuhl at the University of Southampton The Trustees have renewed the General Fellowship to Mr G S Laurence for work at the Atomic Energy Research Establishment at Harwell

City of Paris Medal Awards

At the recent International Conference on Information Processing held at Unesco House, medals of the City of Paris were awarded as follows The Vermeil Medal to Prof Howard H Aiken (United States), Silver Medals to I I Basilewsky for Prof Dimitri Panov (U S S R), Isaac L Auerbach (United States), Maurice V Wilkes (United Kingdom), Adriaan van Wijngaarden (Netherlands), Hideo Yamashita (Japan), Alwin Walther (German Federal Republic), Aldo Ghizzetti (Italy), Stig Comet (Sweden)

Announcements

Sir Hugh Linstead has been appointed a member of the Medical Research Council in the place of the late Mr Richard Foot, M P

Mr Henry Edmunds, county advisory officer for Breconshire, has been appointed assistant agricultural and food attaché in Washington He replaces Mr O G Williams

Dr J H Piddington, of the Commonwealth Scientific and Industrial Research Organization (Australia) Division of Radiophysics, has received the T K Sidey (Summertime) Award, made each year by the Royal Society of New Zealand The Award was given for his theoretical explanation of heating in the atmosphere of the Sun He also received the David Syme Research Prize of the University of Melbourne recently for this work

The following officers of the Institution of Electrical Engineers have been elected *President*, Sir Willis Jackson, *Vice-Presidents*, G S C Lucas, O W Humphreys, *Honorary Treasurer*, E Leete

The Quality Control Group of the Textile Institute will officially come into being on November 10, when a conference on this subject will be held in Harrogate Further information can be obtained from Mr L H C Tippett, British Cotton Industry Research Association, Didsbury, Manchester The inaugural meeting and conference of the Physics Group of the Institute will be held in Buxton on October 8 and 9 Further information can be obtained from Dr H O Pauls, British Nylon Spinners, Ltd, Pontypool

Butterworths Scientific Publications, Ltd, 4–5 Bell Yard, Temple Bar, London, W C 2, announce that a new quarterly journal, *Polymer a Journal to Promote the Science of Large Molecules*, is to appear in October It has been founded to provide an international medium for the publication of original papers on the chemistry, physics and application of polymer research The Advisory Editorial Board consists of Dr C H Bamford, Courtaulds, Ltd, Research Laboratory, Maidenhead, Prof C. E H. Bawn, University of Liverpool, Prof Geoffrey Gee, University of Manchester, and Dr Rowland Hill, research director, I C I Fibres Division, Harrogate

THE WATER POLLUTION RESEARCH LABORATORY

THE Water Pollution Research Laboratory of the Department of Scientific and Industrial Research held open days on May 6 and 7 This organization was formed in 1927, but the Laboratory at Stevenage was not occupied until October 1954 The total staff, which includes chemists, chemical engineers, physicists and biologists, is at present about 120 The Station carries out small-scale and pilot-scale work and also has facilities for work with large plant built in the open, particularly on the treatment of sewage, which can be pumped from a domestic sewer crossing the site It was stated that an additional wing, containing further pilot-scale laboratories, is being designed and that it will probably be built in 1960

The field of work of the Station is in the improvement and development of methods of treating sewage and industrial effluents, and in the study of the effects of pollution on surface waters, including rivers and estuaries Of the work on sewage, part is of an empirical kind and part more fundamental In the first category, for example, the Laboratory is comparing the efficiency of different types and size of medium in percolating filters, of which there is a large experimental installation in the grounds The more fundamental work on sewage includes a detailed study, mostly with pilot plant, of the mechanism and efficiency of aeration in the activated-sludge process, of the factors affecting the drying of sewage sludges, and of the effect of household detergents on sewage treatment Apart from the obvious effects of these materials—that is, the occurrence of foam, often some feet deep, at sewage works—they have caused a marked deterioration in the biological processes of treatment at some works, particularly at those which use the activated-sludge process, in which sewage is aerated either mechanically or by diffused air in contact with an active bacterial floc Work at Stevenage has shown that the immediate effect of detergents is to reduce the rate of transfer of oxygen from bubbles of air to the liquid, and that in those plants where initially the rate of aeration was sufficient only to maintain a comparatively small concentration of oxygen in solution, the further inhibition of oxygen transfer has been responsible for the deterioration observed It was announced recently that manufacturers of detergents were trying to develop surface-active materials which would be more easily decomposed by bacterial action than those at present in use, and in one experimental plant at the Laboratory some of the more promising compounds were being tested by treating them, in admixture with domestic sewage, in small activated-sludge plants In these tests the conditions of operation are controlled , for example, the liquid is aerated with mixtures of air and nitrogen to maintain a desired constant concentration of oxygen in solution Some of the materials submitted for test are much more readily decomposed during sewage treatment than are those at present on the market

A substantial effort is directed to the improvement of methods of treating industrial waste waters, and in this work the Laboratory is closely associated with the Federation of British Industries One investigation now nearing completion has dealt with the anaerobic digestion of certain industrial liquors—for example, those from slaughter-houses—containing high concentrations of organic matter For suitable liquids this process may well be economic—for example, with slaughter-house waste more than 90 per cent of organic carbon is converted to methane and carbon dioxide during a period of treatment of 24 hr —and the process is likely to go into full-scale use in Britain in the near future A plant was also shown in which tannery wastes, which often contain sodium sulphide used for removing hair from hides, is treated with flue gas to neutralize it, the hydrogen sulphide in the flue gas being oxidized to sulphuric acid by biological action in a percolating filter Apart from these long-term projects the Laboratory acts as an advisory service to industry and frequently undertakes short investigations for particular firms on a repayment basis

One important aspect of the work of the Laboratory is the study of the effects of polluting substances in surface waters For some years the chief object of this study has been the Thames Estuary, the central reaches of which in dry weather are anaerobic, and where in consequence sulphate is reduced to sulphide by bacterial action This survey, the final report on which has not yet been published but is in preparation, has involved much experimental work—for example, determinations of rates of oxidation of organic materials at different temperatures, and the study of the conditions in which ammonia is oxidized or nitrate is reduced by bacterial action—the results of which are applicable to the far simpler system of a fresh-water stream In the Thames Estuary the most important effect of pollution of all kinds is to reduce the concentration of oxygen in solution in the water, since it is only when this has fallen to zero (and when any nitrate present has been reduced to nitrogen) that evolution of hydrogen sulphide occurs In fresh-water streams many other effects of polluting substances may be important, particularly if the stream is expected to support a fishery or if the water is used for a public supply, but the lowering of the concentration of dissolved oxygen which results from the discharge of any oxidizable material is still one of the most objectionable results of pollution, and the level of oxygen is often taken as diagnostic of the general quality of the water

In rivers which contain fish, oxygen tension is particularly important, not only because a certain minimum level is necessary to support fish life, but also because a reduction in tension increases the toxicity of any poisons which may be present The Laboratory is studying the various factors which govern the oxygen balance of streams, in the hope of being able to reduce the margin of error with which the oxygen profile below the point of discharge of a given effluent to a given river can be predicted, and has already made some progress in this direction The work has been greatly facilitated by the development of a robust recorder of the dropping-mercury type which can be used to give a continuous record of the level of dissolved oxygen in a river The programme involves a knowledge of the rate of oxidation of polluting substances, of the rate at which the water of a stream will absorb oxygen from the air, and of the effects of aquatic plants and animals on the oxygen balance

In the field, the only satisfactory method at present available for determining the rate of transfer of oxygen from the air is to reduce the oxygen tension in the water (by adding sulphite and a catalyst), following then the rise in level of oxygen below this point This method has been used successfully for small streams, but presents obvious difficulties in a large river Many of the factors involved, however—for example, turbulence, and the presence of substances such as detergents in solution which reduce the rate of oxygen transfer—are being investigated by running water through sloping troughs, 100 ft long, in the grounds of the Laboratory One question which is often important in Britain—namely, the change in oxygen-level in water when it flows over weirs—has been substantially settled by work in the field and in pilot-scale plant, given the height from which the water falls, and the temperature, the extent to which the oxygen deficit is reduced can be predicted within narrow limits

In rivers, oxidation and reduction of compounds of nitrogen often play an important part Oxidation of ammonia and reduction of nitrate, and particularly the effect of concentration of dissolved oxygen on these processes, are being studied in an artificial river in which water passes through a series of tanks fitted with stirrers In streams containing large numbers of algae or much rooted vegetation, the effects of the bacterial oxidation of polluting matter on oxygen tension may be greatly outweighed by photosynthetic production of oxygen and its consumption by plant respiration These effects are being studied in a stream near the Laboratory, where continuous recorders are installed In June and September 1958 there was a net release of 3 8 gm oxygen/m ^{2}/ day Estimates are being made of the productivity of different reaches in this stream using cropping techniques assisted by aerial photographs taken by a camera suspended from a meteorological balloon Consumption of oxygen by respiration of invertebrates is also significant, and this is being determined in respirometers in which the change in oxygen tension is again recorded continuously.

The Laboratory has a small but well-equipped Microbiological Section in which three main lines of work are in progress The first is a detailed study of the changes which occur when aqueous solutions of organic compounds (which may be radioactively labelled) are passed over an active microbial film of the type which occurs in percolating filters and on which the purification of sewage by this process depends The film is built up on the inside of a 'Perspex' cylinder, the long axis of which is inclined and about which it is rotated, the atmosphere in contact with the film is circulated and there are arrangements for withdrawing samples from it and for adding oxygen to replace that used in oxidation Most of the organic substances present in such materials as sewage are very rapidly oxidized ; one object of the work is to identify those which are not

It is very important, in treating polluting liquids by biological processes, to be able, in the last stage of the process, to remove by sedimentation organic sludge from the liquid—the latter representing, of course, the final effluent from the plant A large part of the organic matter to be removed consists of bacteria and the quality of the final effluent depends very largely on whether they will or will not agglutinate in the final sedimentation tank In spite of a good deal of work on the subject, not much is known of the factors which affect flocculation in a treatment plant, these are therefore being studied by the section, using cultures isolated from sewage and sewage effluents

The third line of work which is being pursued in collaboration with the National Coal Board is on the bacterial treatment of waste waters from coke ovens, in which the chief constituents to be removed are phenols, thiocyanate and ammonia Rates of assimilation and oxidation of these substances are being studied in continuous-culture apparatus after preliminary trials by the usual Warburg technique

The Microbiological Section has recently been strengthened by the transfer to it of some of the staff formerly working at the National Chemical Laboratory

WATER SUPPLY AND DEMAND IN GREAT BRITAIN

THE problem of water supply and demand, the need for improved hydrological knowledge and the necessity for a continuing study of the changing situation in Britain, have received editorial notice in earlier issues of *Nature* (172, 823, 1953, and 176, 1133, 1955) The decision to suspend the Inland Water Survey and disband the Central Advisory Water Committee during the economy measures of 1952 was, from a purely scientific point of view, strongly criticized Happily this decision was reversed in 1955 when the Central Advisory Water Committee was reconstituted, and in the same year the Inland Water Survey also recommenced its labours and has since published a great deal of information covering the post-war years

One of the first actions taken by the Central Advisory Water Committee in 1955 was to appoint two subcommittees to investigate information on water resources and the growing demand for water Both these subcommittees have recently reported to the Central Committee and the information collected so far has now been published*

Of the two documents, that of the Subcommittee on Information on Water Resources is perhaps the least controversial and may be considered first This Subcommittee was appointed with the following terms of reference (i) to review the current activities which contribute to our knowledge of the nation's water resources, (ii) to define the additional work needed to make a balanced survey of the quantity and quality of surface and underground water available for domestic, industrial and agricultural use, (iii) to advise on ways of collecting and interpreting the necessary information, correlating it with information from other sources and publishing it

---

* Central Advisory Water Committee Subcommittee on The Growing Demand for Water—First Report Pp iv+28 1*s* 3*d* net Report of the Subcommittee on Information on Water Resources Pp ii+20 1*s* 3*d* net (London H M Stationery Office, 1959)

The review of current activities deals with the work of the Meteorological Office (Air Ministry), the Surface Water Survey Centre (Ministry of Housing and Local Government) and the Geological Survey in providing information on rainfall, evaporation, surface water and ground water It is recommended that the Geological Survey should resume publication of information on ground water , and that all data on rainfall, surface water and ground water should be presented on a common basis of river basin areas The planned future contents of "British Rainfall" and the "Surface Water Year Book" are endorsed, and the proposed arrangements for the collection and interpretation of hydrological information are considered adequate to meet the known need, although certain extensions of existing activities are recommended The more frequent inspection of rainfall stations, the more accurate recording of snowfall, additional recording of ground water, the publication of more data on the quality of certain water supplies and the more rapid completion of the network of river gauging stations are all considered desirable

Although the arrangements for the collection and interpretation of information are considered "broadly [to] meet the known need", the report recognizes the necessity for additional investigation into hydrological relationships and for further inquiry into the use of hydrological information It is therefore also recommended that work at present being done on hydrological research should be reviewed to determine how such work should be co-ordinated and what extensions or modifications may be desirable The lack of any central hydrological information and research organization comparable to the Geological Survey or Meteorological Office has already been noted elsewhere*. The publication of this report on information on water resources really arises from the lack of such a body, since data on the hydrological cycle in Great Britain are scattered among such a variety of authorities each of these authorities is only interested in one aspect of the complete cycle The recommendation that all hydrological results should be presented on a common basis of hydrometric areas is, however, a significant move towards a closer integration of the available data

The report of the Subcommittee on the Growing Demand for Water is a longer document, although despite three years deliberation and investigation it has appeared as a first and not as a final report, for the subcommittee found its terms of reference more exacting than anticipated These were "To consider the extent to which the demand for water for domestic, industrial, agricultural and other purposes is increasing and is likely to increase, to consider the problems involved in meeting these demands, including, in broad terms, the cost , to consider whether there are any substantial economies in the use or cost of water which could be made without reduction in standards of hygiene or in industrial or agricultural efficiency , and to make recommendations"

The main questions which remain unanswered concern the demand for water for agricultural irrigation and economies in the use of water in industry The chief difficulty experienced in the investigation was related to the dual character of water supply in Great Britain which is provided by both public water undertakers and obtained privately and the threefold nature of the demand, which is domestic, industrial and agricultural Accurate statistical information on consumption is readily available only from the public water undertakers, but even here the amounts in the various categories of use are not fully known The subcommittee instituted its own official inquiry among all public water undertakers, the nationalized industries (electricity, coal, gas and transport), and six major industries (brewing, chemicals, iron and steel, leather, paper and textiles) where supplies are largely obtained privately A large and valuable collection of new statistical data has therefore been accumulated , and this, together with the unpublished water surveys carried out between 1945 and 1958 by engineers of the Ministry of Housing and Local Government, form the basis of the recommendations accompanying the report

In the industrial and domestic categories there is clear evidence of a steady nation-wide increase in water consumption of between 2 and 3 per cent per annum during the past quarter of a century This is expected to continue into the future to produce by 1965 something of the order of a 25 per cent increase over the known 1955 consumption figures As new works under construction, or proposed, are scheduled to yield an additional 800 million gallons of water a day by 1965, and this is approximately 40 per cent of the quantity distributed by water undertakers in 1955, the subcommittee concludes that in England and Wales as a whole the rising consumption need not give rise to immediate anxiety This general statement is, however, immediately qualified with the proviso that "this is not to say that temporary or local shortages will not recur from time to time, quite apart from more general shortages in very dry years (when maximum domestic demand and minimum supply tend to coincide), or that industries seeking new sites will find abundant supplies in any place they care to choose" The estimates also assume that in any particular area the trend of consumption will follow approximately its present course, so that any significant deviation not foreseen at present could upset the balance

Beyond 1965 the Subcommittee was "unable to obtain any reliable data" and decided not to attempt numerical estimates The subcommittee is therefore not prepared to commit itself other than to express the opinion that there need be no shortage of water in any part of England and Wales provided that development schemes are prepared well in advance of demand, that the necessary statutory powers and other authorizations are granted, that capital investment is permitted on the requisite scale and the location of industries which require large quantities of water is regulated with the water supply situation in mind

While acknowledging the great amount of work which has clearly gone into the inquiry, and the valuable new information which the report presents, it must be admitted that there are a number of debatable points In the first instance the Subcommittee has based its arguments upon figures of past consumption which are not necessarily indicative of past demand, and could certainly be misleading so far as future demand is concerned This is most evident in the agricultural usage of water Quite apart from the fact that the consumption rises rapidly as soon as piped water becomes available to a farm, there is the whole unresolved and rapidly growing problem of agricultural irrigation The work done at Rothamsted Experimental Station shows, for agriculture, a deficiency of rain in more than five years out of ten south of a line drawn from the Humber to the Severn, and a deficiency in nine years out of ten in Essex, Suffolk and Kent The magnitude of the deficiency varies from place to place and from year to year with theoretical values ranging from 1 in to 12 in of rain The irrigation that would be needed to meet this deficiency would depend on soil moisture retention conditions and plant rooting characteristics, and might amount to a rainfall equivalent in some places of up to 6 in All the water would be used in transpiration or evaporation, or absorbed by percolation, and would not be capable of re-use Calculations indicate that a possible demand of some 8,000 million gallons a day might exist in very dry years south of the Humber–Severn line This amount is more than four times that supplied in 1955 by all the public water undertakers in England and Wales, and it indicates the potential demand which exists and which the subcommittee has ignored in its first report It is proposed, however, to give further attention to this problem, but the approach appears to be negative as the possibility is mentioned of some form of control over the abstraction of surface water analogous to the existing protection of underground water If the national policy is to secure the maximum food output from the agricultural industry, farmers in south-east England should be actively encouraged rather than discouraged to irrigate, in which case a more positive approach to the water supply problem and a completely different attitude of mind are then needed

---

* Balchin, W G V , *Water and Water Eng* , 61, No 734 (1957)

The reluctance of the Subcommittee to look further ahead than 1965 is also unfortunate, although the difficulties can be fully appreciated The Ministry of Health Committee on Causes of Increase in Consumption of Water (1949) was prepared to look ahead for a period of some 22 years up to 1970 Past experience clearly shows that water-supply schemes take many years to come into operation and that reliability in supply largely depends on one generation planning for the next The blue prints to meet the requirements of the late 1970's should be in process of formulation in the early 1960's if the real needs of agriculture and industry are to be satisfied

Possible economies in the use of water in industry have also been deferred for future consideration, although the report does direct attention to waste prevention and leak detection , the recommendation is made that all water undertakers should operate an adequate waste prevention service

There is clearly much food for thought in both of these reports The rising standard of living of an increasing population in Great Britain has, in the present century, brought water to the forefront as a vital and essential commodity in the life of the nation Although the natural resources of the country in terms of rainfall are theoretically adequate, Nature has a habit of distributing the precipitation unevenly in both time and place This situation can only be remedied by care in use and by the conservation of supplies in periods and areas of plenty Lowland Britain, where consumption is greatest, is also the area where the population is densest, the rainfall least and where local water resources are nearing full utilization Highland Britain, on the other hand, has a low population, the highest rainfall and a relative over-abundance of water of which only a small proportion has yet been developed To what extent would the gains from scientific irrigation in agriculture and a guaranteed domestic and industrial supply in lowland Britain outweigh the cost of storage and movement of water from highland Britain ? And how far might the conversion of saline water in Great Britain assist in the solution of the water-supply problem ? It seems that these are the major questions on water supply that must be answered if the problem is to be approached with vision and concern for the needs of the next generation

W G V BALCHIN

TEN YEARS OF ERGONOMICS

ERGONOMICS is mainly about 'human factors' in the design and operation of machines, and about the physical environments in which men use their machines Moreover, it is multidisciplinary Nobody who attended the tenth anniversary meeting of the Ergonomics Research Society, held in Oxford during April 6–9, could have much doubt on either of these points

The Postmaster-General, Mr Ernest Marples, apparently less damaged than he should have been by a 400-mile cycling trip in France on what seems to have been a highly unergonomic saddle, opened the conference He had hard things to say about the word 'ergonomics' Unlike his chairman, the Master of Balliol, who thought it was splendid because it told us exactly what it meant, Mr Marples thought it was frightful because it did not However, for ergonomics itself he had nothing but praise The General Post Office had used it for nine years , and it was his intention to build it into the General Post Office structure so firmly that it could be got out again only by 'positive action' He pledged his support for everyone, everywhere, including housewives in their kitchens, who moved ergonomically with the times

Following up a point Mr Marples made about the frequency with which "backroom boys" are either not understood or misunderstood, Sir Frederic Bartlett, formerly—for twenty-one years—professor of experimental psychology in the University of Cambridge, inquired how common difficulties of communication might be overcome, so that proved advances (for example, in the design of altimeters) might be adopted with reasonable rapidity Mr Marples advised him to get into touch with the top people concerned, or with the Parliamentary and Scientific Committee, or with Mr Marples himself Sir Frederic looked rather less happy about this than did Mr Marples

There was more to come from the General Post Office A paper by Dr R Conrad, of the Medical Research Council Applied Psychology Unit at Cambridge, dealt with mass communication systems , and a couple by Dr W F Floyd, of the Middlesex Hospital Medical School, and Miss June I Jones, of the General Post Office, covered some problems of lighting, posture, thermal conditions and energy cost of work in telephone exchanges and Post Office factories These gave a clear indication of what ergonomics amounted to in practice Dr Conrad told us that to obtain a weather report he had to dial 96618312274 As this kind of thing was spreading, it had been decided that some General Post Office-based studies of immediate memory might pay off One proved useful in comparing conventional dials with push-button arrangements, and another helped in working out the kinds of codes that might be suitable for trunk numbers or postal addresses Dr Conrad's concern with efficiency was matched by the interest Dr Floyd and Miss Jones displayed in comfort, but Dr Conrad led the other two in his theorizing

These three early speakers did, in fact, throw up, without explicit formulation of them, problems which were to rear their heads frequently during the conference What had Dr Conrad in common with Dr Floyd and Miss Jones apart from the General Post Office roof over his head ? All he said—and, indeed, all his director, Mr D E Broadbent, said in a later paper—could easily have been labelled 'applied experimental psychology', and all that Dr Floyd and Miss Jones said is usually called 'applied physiology' Where does ergonomics come in ? Does it seek to be regarded as a new science ? If so, on what is its claim to independent scientific status founded ? Has it any distinctive concepts or methods ? Is it, perhaps, mainly a convenient gathering-place for people belonging to certain technological wings of certain human sciences, and their agents and users in industry ?

As if these puzzles were not enough for us, more were produced by delegates who came from the work-study sector of industry One, Mr A Graham, of Imperial Chemical Industries, created a small squall after some plain speaking by Mr H Murrell, the founder of the Society Mr Graham asked scornfully why industry should be expected to prefer the 'toothpick' of ergonomics to the 'pneumatic drill' of work-study; and having delivered himself of this broadside, he switched on his own pneumatic drill and demanded that work-study practitioners should be offered both help and respect He gave the impression that what was really worrying him was the intrusion of still more outside 'experts' At this point Mr A T Welford, the editor of *Ergonomics*, deftly applied the oil-can However, it seems that later in the day, at the Society's annual general meeting, Dr E A Muller, of Dortmund, set the cat among the pigeons again by suggesting that meetings between research workers and people from industry were a doubtful blessing and should be only occasional

It may appear, from all this, that the conference was a bit of a mix-up So indeed it was But it was probably a healthy one The physiologists and psychologists, though going their separate and unintegrated ways, somehow did battle together with the delegates from industry True, each side paid tribute to the other and to some extent shared a common cause, but the sparks flew Perhaps even more would have flown if the meeting had been held in less academic surroundings The industrial contingent were inclined to be a little shy

The nature and quality of the papers were as mixed as the audience Though the title given to the conference as a whole was "Symposium on Ergonomics, its Place in Industry (Past Progress and Future Trends)", only a few of the contributions played up to it These came mostly at the beginning, from Mr Welford and from Dr O G Edholm, of the Medical Research Council Division of Human Physiology, and at the end, from Mr Broadbent, from Dr E H Christensen, of Stockholm, and from Mr L V Green, of Dunlops The rest were chiefly individual papers Among them were a description of work done on design problems in E M I Electronics, given by Mr B Shackel, and an account of activities in the Clothing and Stores Experimental Establishment of the Ministry of Supply, given by Dr E T Renbourn and Mr H C Stockbridge Mr C E Brooks, of Personnel Administration, Ltd, had some sensible things to say about improving the quality and output of inspectors by systematic re-training, but the information he produced in support of his findings did not carry conviction to everyone; nor did it seem to have much to do with ergonomics

Despite this bittiness, a good deal of stimulation was provided Mr Murrell's own contribution, mentioned earlier, was not what he meant it to be, because a midnight argument had made him decide to scrap the original In the event it turned out to be a usefully provocative statement about what 'ergonomists' could do for industry that methods engineers could not They could bring to their task knowledge of the capacities and limitations of human beings not to be found in the publications of Shaw, Mundel or Barnes More than that, they could bring to it skill in the conduct of experiments with 'chaps' A methods engineer plus a psychologist or half a physiologist would produce a different outlook on industrial problems This was the straight-from-the-shoulder stuff that caused offence to Mr Graham To some others it caused perplexity, for it left unclear the distinguishing characteristics of the ergonomist, the psychologist, and the physiologist A few among the faithful were dismayed, because although they talk about ergonomics, they do not like the label 'ergonomist'

In a comment on a paper by his E M I Electronics colleague, Mr J R Arrowsmith, Mr Shackel had a good point to make about the function of machines in relieving the anxieties of skilled men who build up great tension as the possibility of spoiling several days work mounts So had Mr Broadbent, in the same discussion, when he remarked that in our hopes for the elimination of human error, through the taping of instructions, we must not neglect the risk that the typist typing the tape may err Earlier, Mr W D Seymour had asked, rather drily, how many of the matters discussed at the conference had not been investigated by industrial psychologists twenty-five years ago

So some extent, Mr Seymour's question was answered in a later contribution by the present writer, who made comparisons between the first ten years of ergonomics and the first ten years of occupational psychology The chief differences seemed to lie in the wider scope of occupational psychology It encompassed problems of 'fitting the man to the job' as well as problems of 'fitting the job to the man', and it studied attitudes as well as skills Dangers arising from narrowing the range of the industrial problems taken into account were illustrated by Dr J J O'Dwyer, of Unilever, who spoke about informal groups in industry, and the importance of perceiving and using them, and by Mr R M McKenzie, of the Social Sciences Research Centre at Edinburgh, who showed—entertainingly—how social factors could keep a worker's output well below his potential

What of the next ten years ? If the members of council of the Ergonomics Research Society have not yet drawn their conclusions from their experience of the first decade, they might think about covering the following points in their discussions First, there is perhaps little to be gained by making ergonomics out to be a science It is a kind of conglomeration—not even a compound—of technologies, and it might be a good thing for it to continue like that Possibly the Society should be content to serve the same kind of admirable purpose as the British Nuclear Energy Conference, which pulls in people from a number of fields without seeking to detach any of them from their primary allegiances

Secondly, there is undoubtedly a lot to be said for the running of courses of lectures and practical work for people, from a variety of levels and types of work who are faced with 'ergonomic' problems The short Bristol course outlined by Dr S Griew seems sound in its aim, which is to put across useful facts about the structure and functioning of the human body, to show where more can be found, to explain and demonstrate experimental approaches to problems of equipment design, and to suggest that 'fitting the man to the job' and 'fitting the job to the man' should often be tackled together

Thirdly, however, there is perhaps room for far more stress on the need to look into, learn about and teach people about, individual differences, especially on the psychological side Mr Stockbridge's *cri-de-coeur* ("Individual differences are a frantic nuisance If only we had a standard man ") brought out this need Some workers in this field are clearly tempted, not merely to wish that there were such a creature, but to assume that there is Mr Welford seemed almost to succumb when he spoke hopefully about the discovery of 'standard times' for mental operations, and more particularly when he hinted that one had been run to earth in Antwerp, where telephonists had consistently coped with five bits of information a second Dr Conrad, commenting on this later, unwittingly challenged Mr Welford by revealing that Norwich girls could manage seven without any trouble

Discrepancies like this cannot really be met by jocular references to the possible existence of 'national' differences They must be taken seriously Could they arise from differences in the kinds of people being guided into and selected for the work in different places or at different times? Or from differences in training arrangements? Or from differences in methods of work adopted? Or from differences in equipment? Or from differences in working conditions of several kinds, including the physical, the social and the financial? All these and other possibilities should be explored

But here we encounter two important snags Can exploration of the kind needed be carried out satisfactorily on the tiny, homogeneous, doubtfully relevant groups often used by researchers in the vast field of ergonomics? And can it be tackled adequately by researchers whose devotion to 'precise' measurement is such that they are inclined either to forget or to ignore deliberately the existence of possibly influential factors which lie beyond the reach of their cherished clocks and counters? The state of play in ergonomics ten years from now may depend a good deal on the answers the Council of the Ergonomics Research Society gives to these two questions

Alec Rodger

DISTRIBUTION OF SCIENTIFIC PUBLICATIONS IN UNDER-DEVELOPED COUNTRIES

THE Scientific Publications Council, which has recently been formed, includes the editors of twenty scientific journals and the authors of a number of scientific books It was started by a group of scientists who felt the need for an independent body that could uphold the interests of scientific authors and editors in working for higher standards in the publication and distribution of scientific books and journals The Council is intended to provide a means for scientific writers and editors to maintain contact with each other and exchange views with others concerned in scientific publication in Great Britain and overseas it provides a forum for the discussion of matters of mutual interest and a means of obtaining advice in technical and legal matters relating to publication It is intended that the Council should work to establish good relations between scientific writers and publishers, and co-operate in setting up agreed standards that are acceptable to scientists and publishers alike The officers of the Council are appointed for a term of three years, Prof G W Harris is chairman of the Council and Dr D Richter, Neuropsychiatric Research Unit, Whitchurch Hospital, Cardiff, is honorary secretary

At a meeting of the Scientific Publications Council held on April 10 at the Ciba Foundation, London, Mr John Hampden (British Council) opened a discussion on the distributions of scientific publications in the under-developed countries He described the difficulties experienced in many countries in obtaining British books and periodicals In Asia and Africa there is rapidly growing up a new literate class which wants to read, but in many places no British publications are available In some places it is hard to persuade any bookseller to obtain them, as the necessary currency authorization is difficult, expensive or impossible to get, and the profit is small On the other hand, there is an abundant supply of State-subsidized cheap editions from the U S S R, China and also the United States The English language is now an international possession The students wanting books are the scientists, professional men and leaders of the future, and it is bound to affect their future reading and outlook if the only books they can get are not British

Currency shortages are mainly responsible for the situation in some countries, including Poland, Turkey, Israel, Pakistan and Indonesia How can people in these countries buy British books and periodicals if they have no sterling to pay for them? Other difficulties in some countries include the shortage of bookshops stocking British books and the lack of libraries where British publications can be seen The difficulty is especially acute for scientific and medical books, which are needed by specialists In the Western countries where libraries are largely taken for granted, it is hard to realize that in many places a student may have access to very few books which he does not buy for himself, and the cost of one book may be more than a whole month's salary In many places it is even impossible to get up-to-date lists of British books and their very existence is in danger of being forgotten

The Americans have got round the currency restrictions by export schemes in which the publishers are paid directly by the Government, so that the importing countries need no dollars to pay for books This was originally a British idea (invented by Sir Stanley Unwin) which the Americans have adopted British text-books have been deservedly popular in Asia and Africa for many years, but there is a serious danger that they will soon be swept out of some important markets Mr Hampden said we are not afraid of fair competition, but British publications cannot compete with exports heavily subsidized by foreign governments It is a matter of considerable concern to those familiar with the situation that the journals of many British learned societies are not organized as the book-publishers are to increase their sales overseas, and it looks as though these journals are getting seriously left behind It is essential that more information about British scientific books and journals should be made available overseas The British Council is doing all it can to spread this information abroad

Dr P Rosbaud said that the cultural importance of scientific books has only recently been appreciated in Great Britain The export of scientific and technical books is not only of benefit to the book trade but also has a far-reaching influence on education and commerce in general, so that it pays high political dividends as well One of the main factors influencing distribution abroad is the cost Why are scientific books so expensive in comparison with other books of similar size, and where do all the profits go ? For a typical book of 250 pages selling at 30*s* the publisher may hope to sell 3,000 copies and break even at 2,400—if he sold less than 2,400 he loses , if more, he gains For such a book the printer's estimate may be 8*s* a copy, including the cost of correction, blocks and paper There is little to be saved by using paper of cheaper quality The publisher's overheads might be 2*s* 6*d* , advertising 2*s* and the author's royalty at 12½ per cent would be 3*s* 9*d* Allowing 33 per cent, or 10*s* for the bookseller, that left the publisher with only 3*s* 9*d* as his profit In any sales in the United States the publisher may need the services of an American distributor who would ask 50–60 per cent of the selling price, and the British publisher would also have to pay the additional cost of freight There is the alternative of selling a small number of books at a high price or a larger number at a lower price, as with text-books Text-books have got to be cheap, and this might be achieved by bringing out a large first issue of 5,000 copies without profit and then making a profit on subsequent issues It was not right that the author should ever be asked to waive his royalty, which was little enough anyway no reputable publisher would ever ask that In the publication of scientific journals great patience might be needed before a profit could be made Sir Richard Gregory had told Dr P Rosbaud that *Nature* took more than twenty years before the circulation was sufficient for it to make its first profit Publishing a journal is like cultivating a garden in which one must wait a long time for the harvest As the circulation increases and the journal gradually becomes more profitable, the publisher can pass some of this on to the consumer by reducing the price or increasing the size Scientific journals could be made considerably cheaper by including advertising space Otherwise, the only way of reducing the cost is to increase the circulation Where publishing is a government monopoly, as in the U S S R , books and journals can be produced at a very low cost , but there are objections to this practice Such publications may have plenty of room for the Lysenkos, but not for the Vavilovs and Pasternaks, and the results are tragic There is an urgent need for the British Government to develop an effective export scheme in answer to the floods of cheap State-subsidized publications from other countries

The chairman, Prof G W Harris, asked how scientists in Britain could best help in getting scientific books and journals distributed in the countries that need them Mr Hampden thought that the Scientific Publications Council might help in bringing the problem to the notice of the learned societies Dr F. N L Poynter described the work of the Wellcome Historical Medical Library in collecting scientific books and medical journals and distributing them in under-developed countries abroad He thought it would be helpful if the existence of a voluntary distributing centre of this kind were made more widely known

MAPPING VEGETATION

AN international symposium on mapping vegetation was held during March 23–26 in Stolzenau/Weser, in the Federal Republic of Germany This gathering of 112 scientists from sixteen countries, including Japan and the United States of America, was organized by the head of the Bundesanstalt fur Vegetationskartierung, Prof R Tuxen (Stolzenau), on behalf of the International Society for Plant Geography and Ecology

The rapid progress of phytosociology (phytocenology) in this century, especially during the past three decades, has made feasible the scientific mapping of vegetation based upon well-defined plant communities In view of recent advancements in this field, an international meeting to facilitate exchange of views, personal contacts and assessment of new future developments was very timely

Mapping of vegetation at the Bundesanstalt fur Vegetationskartierung (formerly Zentralstelle fur Vegetationskartierung des Reiches) began in 1931 for the Nature Conservancy Service in Hanover Then, as now, the mapping of vegetation was preceded by extensive field work on existing plant communities in the respective area by the methods of the Zurich–Montpellier school of phytosociology In addition to fundamental research on plant communities, their ecology and distribution, a large variety of applied research programmes have been completed which involved mapping actual and potential vegetation for various practical aims in agriculture, forestry, water supply, transport and nature conservancy At present, a large programme of vegetation mapping has been undertaken for the West Germany railways, in which the vegetation along about 30,000 km of its railway network will be mapped to provide a sound basis for certain practical measures For some time the Institute has been working on a complex research problem concerning the relationship of a particular plant community to the soil profile, and members of the symposium were much impressed by the exhibition of about 300 large, well-prepared soil profile mounts from north-west Germany In solving many complex problems on vegetation for Germany, this independent research institute has become indispensable to other neighbouring countries in Europe, which face similar problems of a fundamental or applied nature It is hoped that recent progress will be maintained and its sound future development preserved

The papers presented at the conference may be subdivided into three major groups (*a*) methods, (*b*) recent advances, and (*c*) applications

(*a*) *Methods* The importance of fundamental principles, methods and aims is of much concern in any mapping of vegetation In his introduction, Prof M Schwickerath (Aachen) referred to the significance of 'association diagrams' in mapping, by illustrating this with examples of the *Violon calaminariae* and *Sphagnum* associations Prof A W Kuchler (Kansas) explained the compilation of a small-scale vegetation map of the United States and the various problems involved Prof A Scamoni (Eberswalde) presented the new vegetation map of the East German Republic on a scale of 1 1,000,000 and indicated the principles applied in this work Prof I Horvat (Zagreb) referred to the basic considerations in applying higher units of vegetation while outlining the main features of vegetation in Yugoslavia Prof A Noirfalise (Brussels) reviewed the aims and methods used in mapping the vegetation of Belgium, and those for recording marine biocenoses of the sea bottom off the coasts of France were outlined by Dr R Molinier (Marseilles) On this topic Dr Molinier gave a lecture illustrated by excellent colour slides of underwater scenes taken on various trips in the Mediterranean Prof H Gaussen (Toulouse) explained the choice of colours in cartography, illustrated by his excellent bioclimatic maps of Africa and South America The following five papers from the Bundesanstalt fur Vegetationskartierung dealt with the main principles, methods and techniques adopted there Dr W Trautmann discussed his field experiences, and Dr W Lohmeyer assessed the value of aerophotography Prof R Tuxen stressed the importance of mapping potential vegetation, which is more advantageous in forestry than the actual vegetation Dr K Walter spoke on introductory courses in phytosociology held in Stolzenau, and Dr A Wenzel explained techniques in cartography employed there

(*b*) *Recent advances* The advances made in recent years in phytosociology in various countries and the value of vegetation maps in related fields of science constituted the second topic of the symposium Dr A E Apinis (Nottingham) stressed the relationships of soil micro-organisms to higher plants and the value of vegetation maps for the fundamental research in soil microbiology Prof F Major (Davis, California) outlined the basic approach to vegetation necessary for their mapping on a scale of 2 in to 1 mile, while Mr A. Miyawaki (Yokohama) dealt with the occurrence in Japan of snow-patch communities similar to those of the European mountains Mr S Bertovic (Zagreb) described vegetation mapping in Croatia and in other parts of Yugoslavia, while Dr A O Horvat (Pecs, Hungary) presented a detailed map of forest phytocenoses of the Mecsek Mountains in southern Hungary, and Dr R Neuhausel (Brno) spoke on mapping natural vegetation in Moravia Mr I S Zonneveld (Sleeuwijk, Holland) explained the mapping of both alluvial soils and vegetation in the tidal fresh-water area of the Rhine delta, combining the direct field method with that of aerial photography Mr Doing Kraft (Wageningen) is using physiognomic characteristics in recording the unstable dune vegetation near Harlem Dr J Tuxen (Stolzenau) spoke of the application of vegetation maps in solving problems in the historical investigation of rural landscape, while Prof J Schmithusen (Karlsruhe) emphasized the significance of vegetation maps of various scales in phytogeography and other related sciences.

(*c*) *Applications* The variety of purposes to which the mapping of vegetation may be applied was revealed by the following papers, which were illustrated by a number of excellent large-scale maps Prof A Matuszkiewicz (Warsaw) spoke of developments in phytosociological mapping in Poland and its present applications The possibilities of ecological and phytosociological mapping for applied purposes was discussed by Dr G Long (Montpellier) Prof P Fukarek (Sarajevo) outlined the application of vegetation maps in the forestry work of Bosnia and Herzogowina, and Prof M Wraber (Ljubljana) explained the use of the general map on a scale of 1 100,000 of potential natural vegetation of north-west Yugoslavia as a basis for re-afforestation work on the degraded Karst and Flysh areas The paper of Mr K Mraz and Mr V Samek (Prague) on certain problems on the cartography of vegetation and its applications in forestry was read by Prof R Tuxen

The mapping of vegetation is regarded as the best approach to solving problems of water relations in various plant communities On this aspect Prof H Wagner (Vienna) reviewed the mapping of vegetation for certain purposes in connexion with hydroelectric works in Austria, while Dr K Meisel (Stolzenau) spoke on its importance for the assessment of damage to vegetation due to water Dr P Seibert (Munich) showed the application of phytosociological mapping of 'Pupplinger Au' near Munich to the water economy service there, and an assessment of damage due to salt water to meadows of the Werra Valley was given and its prevention planned on the basis of a vegetation map described by Dr B Speidel (Bad Hersfeld) According to Mr Th A de Boer (Wageningen) mapping of various grasslands in Holland has been combined with soil mapping to provide an efficient agricultural advisory service in certain areas Prof L Steubing (Giessen) found the regular occurrence of certain grassland communities in areas where wind-break hedges are common The importance and practice of mapping Alpine grasslands in Oberengadin was demonstrated by Dr F Marschall (Zurich) The two last papers dealt with certain aspects of nature conservancy Dr E Preising (Hanover) reviewed mapping of vegetation in relation to problems of nature conservancy and landscape, and Mr P Tideman (Doorwerth, Holland) found direct mapping combined with aerial photography very useful in the management of the various protected areas in Holland

Two decisions of general interest may be briefly mentioned (1) A permanent commission was formed for the preparation of a vegetation map of Europe, with Prof R Tuxen (Stolzenau) as chairman and the following members Prof J Braun-Blanquet (Montpellier), Prof L Emberger (Montpellier), Prof I Horvat (Zagreb), Prof A Noirfalise (Brussels) and Prof B Pawlowski (Cracow) (2) The following resolution was adopted for submission to Unesco and all the member Governments concerned "The vegetation of the Earth represents the vital productive potential upon which all life depends Therefore, the comprehensive study of vegetation is of the utmost importance, and for this purpose the combination of ecological, phytosociological and cartographical methods are required

"The present-day methods of mapping vegetation greatly enlarge our fundamental knowledge of plant communities, their development and distribution as well as providing a deep insight into their environments In applied phytosociology the mapping of vegetation constitutes a solid basis for assessment of habitats, for utilization of vegetation, and for the evaluation, or even the forecasting, of any change or damage to vegetation by erosion, wind, water and other natural or human factors

"It is suggested that no large-scale technical measures should be planned or carried out which may influence the vegetation or landscape without first mapping the vegetation prior to the respective technical measures being put into effect "

A E Apinis

BIOLOGICAL FIBRES

It is some time since the X-ray Analysis Group of the Institute of Physics has met to consider biological fibres, so that the conference in Leeds held during April 17–18, even if only partly devoted to fibres, was very welcome It is, however, symptomatic of the present place of specialist techniques (even if they are as well established as X-ray diffraction) in such fields as the study of fibre structure, and perhaps even more of the trend of development of the corresponding specialist groups, that of the seven papers presented on this occasion only two could be classed as predominantly crystallographic in content, whereas in two others, which dealt respectively with infra-red absorption and the electron microscope, X-rays had no more than a casual mention That these other techniques are now essential partners with X-ray diffraction in research on fibre structure was emphasized by the part they played in the other three papers Nevertheless, in this account attention will be confined chiefly to topics which are more closely associated with the nominal activities of the Group

The successful study of the cellulose fibre by X-ray analysis set a fashion which is evidently, even after more than thirty years, not yet outmoded This fibre is still presenting fundamental crystallographic problems for investigation, for example, it seems still to be possible to argue about whether the cellulose chain molecules are all oriented in the same sense, or form two antiparallel systems D W Jones and his colleagues (British Rayon Research Association) are non-committal about it in their discussion of cellulose I, but favour alternation in cellulose II Prof R D Preston (Leeds) suggests that in cellulose I alternation is unlikely, basing his argument on the idea that growth is by end-synthesis His conclusion was, however, criticized in discussion, and also seems impossible to reconcile with the almost universal acceptance of alternation in cellulose II, although whether this is necessary or merely a convenient dogma is not at all clear It does seem reasonable to expect that, if chain polarity is of any significance at all, the same type of arrangement will be present in both modifications

Another controversial feature is the type of hydrogen bonding, about which there are two schools of thought respectively accepting or denying the presence of diagonal hydrogen bonds (specifically perpendicular to the [101] normals in the Meyer and Misch cell) The orthodox, among them the British Rayon Research Association team, agree with Meyer and Misch at least on this one point, that the hydrogen bonds are parallel to the *a*-axis of the unit cell. Both schools have recently adduced infra-red absorption results in favour of their arguments, creating further confusion for the non-specialist

Agreement does seem to be reached on one point, that there is more than one cellulose I structure, the eucellulose (Preston) or type *A* cellulose (Marrinan and Mann) of *Valonia* must, one supposes, be cellulose I proper, ramie, the typical type *B* cellulose, is classed with most of the other plant fibres as yielding on hydrolysis, besides glucose, other sugars which are to be regarded as contaminants

Some fibrillar aspects of the fine structure of cellulose also received attention Preston believes that the microfibrils retain their identity when surrounded by incrustants in the cell wall, and that their surface structure is in some way responsible for the electron diffraction patterns which he and his colleagues have obtained from metal–cellulose complexes

The application of X-ray analysis to the problem of the structure of silk fibroin is nearly as old as its application to cellulose, and we have been accustomed for a long time to distinguish between the structures of the two principal silks of commerce, domestic and tussah It is now clear that these are but two of a family of at least six fibroins produced by various members of the orders Lepidoptera and Araneae, the silks produced by some fifty species were examined by J O Warwicker (Shirley Institute, Manchester) to establish this A disturbing observation is that there appears to be no strict correlation between the crystallographic type of the fibroin and the biological classification of the producing species Structurally, the fibroins differ in the separation of the hydrogen-bonded pleated sheets of polypeptide chains, this distance may be as small as 9 3 A (*Bombyx mori*) or as large as 15 7 A (*Nephila senegalensis*) In fibroins with the larger inter-sheet separations amino-acid residues with long side-chains must occur in the crystalline regions In view of the importance of this idea, which has always been virtually rejected before in theories of fibroin structure, further details of the relevant chemistry would be welcomed

The cross-β configuration, so extensively studied in the keratin–myelin–elastin–fibroin group of fibrous proteins, has always been something of a puzzle because of the difficulty of obtaining a good X-ray diffraction diagram That a solution of the problem should now be given in terms of a structure closely allied to a fibroin rather than to keratin is one of those oddities which sometimes arise in fibre structure research K D Parker and K M Rudall (Leeds) have found, in fact, a cross-β fibroin in the egg-stalks of the lacewing fly, it gives a remarkably good X-ray diffraction pattern the interpretation of which leaves no doubt that the fibroin chain-molecules are arranged in long folds transverse to the fibre-axis From this folded configuration the chains can be brought into the parallel-β state by stretching the material to about six times its initial length This change is regarded as a true intramolecular transformation like the α–β transformation in keratin, but differs from the latter in that so far no success has followed attempts to reverse the change

Heavy-metal staining techniques are of great importance in electron microscopy, and are now being successfully employed in studies of the microfibrillar texture of keratin fibres Work is going on in various centres to correlate such electron microscope observations with the older X-ray results that mercury, for example, can modify the intensities of the equatorial 'reflexions' at approximately 80 A, 45 A and 27 A in keratin H J Woods (Leeds) reported that staining with mercuric acetate also affects the wide-angle diffraction pattern, when corrections are made for increased absorption due to the metal In an attempt to account for the small-angle 'reflexions' in terms of a model of uniform microfibrils it is found that conventional Fourier transform methods for obtaining the radial distribution of interfibrillar vectors are inapplicable, and the direct method of calculating the intensity from an assumed radial distribution often results in a negative intensity In the discussion it was suggested that there might be a failure of the conventional theory for systems so nearly close-packed as those considered, but it now seems more likely that the difficulty is due to the fact that for such systems the radial distribution must be so nearly determined by geometry that the use of an arbitrary distribution may well be physically unsound J Sikorski emphasized that the electron microscope results so far tell us only about the details in para-cortical cells, the size and packing of the microfibrils in the ortho-cortex may well be different H J WOODS

THE SMITHSONIAN INSTITUTION

REPORT FOR 1957–58

THE report of the Smithsonian Institution for the year ended June 30, 1958*, covers the 112th year of the Institution and includes the report of the Secretary and the financial report of the Executive Committee of the Board of Regents, together with reports of branches of the Institution and on the library and publications The Institution has now nearly 51 million catalogued objects in its collections, and visitors to all its branches totalled more than 10 36 million Field work during the year included the excavation of the Welcome Mound along the Ohio River in West Virginia, continued field investigations of the bird-life of the Isthmus of Panama, and the mammal survey of Panama, a long-range programme designed to solve the stratigraphic sequence in the Glass Mountains, and extensive palæontological work in Oklahoma, Texas, New Mexico and Colorado

Systematic researches by the staff of the Bureau of American Ethnology included Eskimo and arctic studies, field-work in South Carolina, among the New York Seneca and in Florida, and excavations at Russell Cave, Alabama The director of the Bureau continued also as director of the River Basin Surveys, which continued its programme for salvage archæology in areas to be flooded or otherwise destroyed by the construction of large dams By June 30, 1958, 254 surveys and excavations had been made in twenty-nine States and 4,889 archæological sites located, of which 997 had been recommended for excavation or limited testing; by the end of the year, 388 sites in fifty-two reservoir basins in nineteen States had been partly or extensively dug

The Smithsonian Astrophysical Observatory continued to work along the four principal lines of solar astrophysics, meteors, the satellite tracking programme and studies of the upper atmosphere, in which methods based on celestial mechanics were developed for inferring the density of the upper atmosphere from the motions of artificial Earth satellites, and a theoretical study of the nature and thickness of the lunar dust layer was completed Its Division of Radiation and Organisms continued studies on photomechanisms in plants, with special emphasis on growth responses controlled by low levels of red and blue radiant energy Studies of the interaction of gibberellin, kinetin and cobalt with the photo-process indicate that there is no direct interaction between red irradiance and the added substances, although all these materials modify the final growth response Studies were continued on the effects of radiant energy on the biosynthesis of protochlorophyll in leaves of higher plants grown in the dark, and in a study of biochemical changes involved in the development and maturation of the chloroplast of higher plants, some progress was made in isolating intact proplastids from leaves grown in the dark

---

* Smithsonian Institution Report of the Secretary and Financial Report of the Executive Committee of the Board of Regents for the year ended June 30, 1958 Pp x+232+14 plates (Washington, D C Government Printing Office, 1958)

Good progress is reported in locating a site for a new building for the National Air Museum, to which 193 specimens in 52 accessions were added during the year The National Zoological Park, to which 1,411 animals were added during the year, now totals 2,316 individual specimens, and visitors exceeded 4 million, while those to the Canal Zone Biological Area totalled 570, of whom forty-three were scientists, students or observers using the station for scientific work, particularly in wild-life observation, plant and insect studies and photography The International Exchange Service handled 1,094,798 packages, including 63 full and 43 partial sets of United States official publications in exchange for official publications sent by foreign Governments for deposit in the Library of Congress The Library received 53,274 publications during the year, and arranged 128 new exchanges Its holding at the end of the year totalled 974,893, including 586,722 in the Smithsonian Deposit at the Library of Congress The report includes a list of the 81 new Smithsonian publications issued during the year

---

EFFECT OF NITROUS ACID ON TOBACCO MOSAIC VIRUS: MUTATION OR SELECTION?

By F C BAWDEN, F R S

Rothamsted Experimental Station, Harpenden, Herts

GIERER and Mundry[1,2] claim that treating preparations of tobacco mosaic virus or of its nucleic acid with nitrous acid *in vitro* causes mutations Indeed, they state that their "experiments show that replacement of one single NH_2-group by one OH-group *in vitro* can change the genetic character of the whole TMV-RNA molecule"[2] The genetical implications of this statement are so great that, before accepting it, there is more than usual need to ensure that their experiments could have no other interpretation What their results show is that, when tobacco mosaic virus is treated with nitrous acid, its infectivity, as measured by the numbers of local lesions formed in one tobacco variety, Xanthi, decreases, while the number of necrotic lesions produced in another variety, Java, increases Xanthi forms necrotic local lesions with all the usual strains of tobacco mosaic virus, whereas Java forms them with only some and not with the type strain

These results are readily reproducible Table 1 shows two experiments with the Rothamsted type culture of tobacco mosaic virus , in one, inoculations were made to Xanthi and Java and in the other to *Nicotiana glutinosa* L , which like Xanthi gives necrotic local lesions with the type strain, and to Judy's Pride, a variety of White Burley, which, like Java, does not The starting preparation, like those used by Gierer and Mundry, produced a few necrotic lesions on Java and Judy's Pride There is nothing unusual in this, for all bulk preparations of tobacco mosaic virus contain a mixture of strains However, this being so, it is obviously necessary to consider whether the change in behaviour of the preparations towards the different plants during inactivation by nitrous acid could simply reflect some form of selection from a mixed population of strains Gierer and Mundry state that this possibility is excluded because the total number of lesions produced on Java increases and not simply the ratio of lesions on Java to those on Xanthi They therefore conclude that the number of particles able to cause necrotic lesions on Java must have been increased by exposure to nitrite But must it ? Their conclusion rests on the assumption that strains do not interact and that one will always produce its characteristic effects regardless of how much of other strains is present

Table 1 NUMBERS OF NECROTIC LESIONS PRODUCED BY DIFFERENT *Nicotiana* SPECIES AND VARIETIES WHEN INOCULATED WITH TOBACCO MOSAIC VIRUS TREATED FOR VARIOUS TIMES WITH NITROUS ACID

Time (hr)	Numbers of necrotic lesions per leaf			
	Exp 1		Exp 2	
	Xanthi	Java	*N glutinosa*	Judy's Pride
0 0	300	0 5	350	2
0 5	250	9	300	12
1	122	24	210	20
2	98	26	130	28
4	33	12	60	33
20	6	0 5	10	15

Tobacco mosaic virus at 4 mgm /ml was incubated with 1 *M* sodium nitrite and 0 25 *M* acetic acid at *p*H 4 1 for the times stated, when samples were diluted 1/10 in *p*H 7 phosphate buffer and used as inocula Xanthi and *N glutinosa* give necrotic local lesions with the type strain of tobacco mosaic virus, Java and Judy's Pride do not

Table 2 NUMBERS OF NECROTIC LESIONS PRODUCED BY DIFFERENT *Nicotiana* VARIETIES AND SPECIES WHEN INOCULATED WITH MIXTURES OF TOMATO AUCUBA AND TOBACCO MOSAIC VIRUSES

Inoculum	Numbers of necrotic lesions per leaf			
	Exp 1		Exp 2	
	Xanthi	Java	*N glutinosa*	Judy's Pride
Aucuba alone	95	240	66	75
Aucuba in TMV 20 mgm /l	130	180	128	60
Aucuba in TMV 200 mgm /l	380	24	350	14
Aucuba in TMV 2 gm /l	500	2	400	4
TMV 2 gm /l alone	500	3	450	2

The tomato aucuba mosaic virus was used at 10 mgm /l With the high concentrations of tobacco mosaic virus (TMV) the lesions on Xanthi and *N glutinosa* were too many to count accurately

There is much evidence at variance with this assumption For example, it has long been known that infection of a plant with one strain of tobacco mosaic virus prevents other strains from producing their characteristic effects[3] and that adding type tobacco mosaic virus to inocula of strains that produce necrotic lesions in Judy's Pride tobacco decreases the number of lesions they produce[4] One such strain is tomato aucuba mosaic virus, and Table 2 shows how mixing this with various amounts of tobacco mosaic virus can affect the number of necrotic lesions formed on Java and Judy's Pride Decreasing the amount of tobacco mosaic virus reproduces the phenomenon, which in treatments with nitrite Gierer and Mundry say can only be attributed to mutations, of decreasing the numbers of lesions produced on Xanthi and *N. glutinosa* while the numbers on Java and Judy's Pride increase. Numbers of necrotic lesions, however, do not tell the whole story, for mixing aucuba mosaic virus with tobacco mosaic virus alters the type of lesion produced, especially on Java. Aucuba mosaic virus alone produces distinctive, reddish-brown circles that may reach a diameter of 0.5 cm. None of the lesions recorded in Table 2 as formed by inocula containing the larger amounts of tobacco mosaic virus was of this type, but all were white spots and flecks of various sizes. With smaller amounts of tobacco mosaic virus, the lesions were more variable; some were all white, but others had small reddish-brown centres, and some approximated to true aucuba type. More of the last type occurred as the concentration of tobacco mosaic virus decreased.

Similarly, when mixtures containing 4 mgm./ml. tobacco mosaic viruses and 20 mgm./l. aucuba mosaic virus were diluted 1/10 in *p*H 7 phosphate buffer and inoculated to Java, only white lesions were formed, whereas a range of types was produced after incubation with nitrite. The first brown lesions to appear were small, but as the treatment continued they became more typical of the aucuba type. It is highly unlikely that adding aucuba mosaic virus to the starting preparation directed any mutations caused by nitrite towards characters peculiar to aucuba mosaic virus, and a more reasonable interpretation is that the residual aucuba mosaic virus became increasingly able to make itself evident as the concentration of infective tobacco mosaic virus decreased. This interpretation does not demand that aucuba mosaic virus should be more resistant than tobacco mosaic virus to inactivation by nitrite, for the ability of the latter to obscure the presence of aucuba mosaic virus is not determined only by the proportions of the two. Concentrated tobacco mosaic virus will obscure proportionally more than will dilute virus; for example, whereas 2 gm./l. will obscure 20 mgm./l. aucuba mosaic virus, 0.2 gm./l. will not necessarily mask 2 mgm./l.

The fact that the obscuring ability of tobacco mosaic virus increases with increasing concentration may simply reflect one aspect of the well-known interference phenomenon, that infection by one strain makes cells resist infection by others. The more concentrated the tobacco mosaic virus, the more epidermal cells it will infect at inoculation and the fewer there will be for aucuba mosaic virus to multiply in unhindered. Indeed, the range of local-lesion types in Java produced by mixtures of the two may mean only that, in different parts of the leaf, different proportions of cells contain one or other of the two strains. However, it is equally possible that there are other interactions between the strains as they multiply, leading, perhaps, to genetic recombinations or phenotypic mixing. This could be decided only by isolating the viruses present in different lesions and testing their behaviour when transmitted to a range of plants. Whatever may be the mechanisms of the interaction between strains, there is no doubt that strains able and unable to cause necrotic lesions in Java tobacco do interact and that this interaction affects both the quantity and quality of lesions produced. The experiment recorded in Table 2 shows fewer local lesions on Java when aucuba mosaic virus was mixed with tobacco mosaic virus than when inoculated alone; but the mixtures sometimes produced more lesions, though no lesion was then of the aucuba type and all were white spots, rings or flecks. Obviously the interactions are complex, but the fact that they occur makes the counts of necrotic lesions produced by mixtures of strains valueless for indicating the numbers of particles present that are intrinsically able to cause necrosis in Java. There seems no reason to look further for an explanation of the action of nitrite in increasing the numbers of lesions produced by tobacco mosaic virus in Java than that, as the concentration of particles unable to cause necrosis decreases, so they interact less with those able to cause necrotic lesions.

The phenomena that suggest mutation come from interactions between infective particles; but there is also an interaction between virus inactivated by nitrite and active virus. Inactivation by nitrite is an effect on the nucleic acid, and inactivated virus particles still retain their physical and serological properties, as do those inactivated by ultra-violet radiation. Like virus inactivated by ultra-violet radiation[5], and like the protein produced when virus particles are disrupted by alkali[6], nitrite-inactivated virus inhibits infection by active particles, and the presence of 0.4 mgm./ml. of such inactivated virus will halve the number of lesions produced by tobacco mosaic or aucuba mosaic virus at 10 mgm./l. This inhibition could affect measurements of inactivation rates, for as the amount of inactivated virus increases so it will increasingly inhibit infections by the residual infective virus, the amount of which will thereby be increasingly under-estimated and preparations will cease to infect while they still contain potentially infective particles. The virus protein is likely to be responsible for the inhibition, so tests with nucleic acid preparations are probably free from this complication; it was with these that Mundry and Gierer[2] found that inactivation follows first-order kinetics. Their conclusion that changes in single NH_2-groups cause mutations derives from the observation that the numbers of necrotic lesions produced on Java at first increase linearly with time; but this need mean little more than that the dominating strain in their starting preparation inactivated according to first-order kinetics. That their starting preparation did contain strains already able to cause necrosis in Java is clear, and that these were interacting with other strains is strongly suggested by the fact that, when diluted 1/10, the number of necrotic lesions on Xanthi fell to one-fifth whereas the number on Java was only halved.

The isolations Mundry and Gierer[2] made from single local lesions in Xanthi also show their starting preparation was mixed. Most of the isolates made from 60 lesions produced by nucleic acid after 90-min. exposure to nitrous acid differed from type tobacco mosaic virus, whereas only 1 out of 65 isolates made from the starting preparation was obviously different. This fact they advance as further evidence that nitrite caused mutations; but as the treated preparation had lost more than 99 per cent of the initial infectivity, 99 times as many lesions should have been sampled from the untreated as from the treated preparation to make a proper comparison. Had 6,000 lesions been sampled, there is every reason to think that more than 100 isolates differing from tobacco mosaic virus would have been found, for the fact that one was identified for certain from 65 lesions suggests that at least 2 per cent of the particles in the starting material differed from type tobacco mosaic virus.

I have made no tests to see whether different strains differ in the rate at which they are inactivated by nitrite; but it is to be expected that they will, for strains have been found to differ in their susceptibility to inactivation by most other treatments. The obvious place to look for resistant strains is among those that survive at the tail end of an inactivating treatment, and all that is needed to explain the preponderance of variants after exposure to nitrite is to postulate that strains differ in their rate of inactivation. That the isolates when propagated continued to show their characteristic differences from type tobacco mosaic virus is interesting, but has no relevance to the problem of how they came to be genetically different from the type virus. Mutations no doubt reflect chemical changes in the nucleic acid, and there is no *a priori* reason why changes produced *in vitro* should not affect the genetic behaviour of viruses, but to attribute mutations to such changes requires more than demonstrating that the end-products of an inactivating treatment differ in behaviour from the bulk of the starting material; it requires demonstrating that chemical changes produced *in vitro* are perpetuated in the progeny of the particles.

I am indebted to Dr. A. Gierer for providing me with seeds of the tobacco varieties Xanthi and Java.

CHARACTERS ASSOCIATED WITH PARASITISM IN GRAM-POSITIVE BACTERIA

By DR. K. A. BISSET
Department of Bacteriology, University of Birmingham

THE concept of parasitism in bacteria has been overshadowed by the more immediate problems of pathogenesis, so that, in standard bacteriological literature, the words parasite and pathogen are treated as if they were synonymous, and harmless parasites are inaccurately designated commensals. Parasitism, properly so called, is common among bacteria, especially of the Gram-positive group, and it is the purpose of this article to indicate certain interesting conclusions that are derived from a consideration of the characters associated with its occurrence.

Many members of the Gram-positive group are not, in fact, Gram-positive in their staining reactions, but nevertheless bear so close a resemblance to the other members of the group in every other respect that they must be considered to have lost this characteristic secondarily. In very many instances, these are parasitic representatives of mainly free-living families. An obvious example is *Neisseria*, a genus consisting of obligate parasites, many of which have lost all trace of Gram-positivity, while retaining characters of morphology, metabolism, antibiotic sensitivity, etc., that indicate a relationship with the Coccaceae. (Their description as obligate parasites refers to their normal mode of life, and does not exclude the possibility of growth in artificial culture.)

A second important character associated with parasitism is anaerobiosis. So far as I am aware, all truly Gram-negative bacteria are aerobic; the so-called Gram-negative anaerobes, such as *Veillonella*, *Fusobacterium* or *Bacteroides*, have obvious affiliations with Gram-positive families, and these also are obligate parasites. This combination of characters is well known in the facultatively parasitic clostridia, many of which are very weakly Gram-positive, whereas the aerobic, sporing bacilli, few of which are parasitic, are strongly Gram-positive. Anaerobiosis without loss of Gram-positivity is found in the parasitic *Actinomyces*. The streptococci would serve as examples, in view of their lack of catalase, but most species are aerobic by virtue of their insensitivity to hydrogen peroxide.

The third character associated with parasitism in Gram-positive bacteria, as indeed in animals and higher plants also, is loss of structural complexity; although the bacteria are exceptional in that they commonly undergo a reduction in the organs of distribution.

Thus, in respect of these various characters, there is quite often found to exist a series of forms connecting a Gram-positive, aerobic saprophyte of complex morphology, with a Gram-negative, anaerobic parasite of simple morphology.

(*A*) The free-living sarcinae are large and strongly Gram-positive; they are aerobic, and include representatives which, by virtue of their possession of flagella and spores, attest a recent common origin with the sporing bacilli. The facultatively parasitic micrococci and staphylococci are Gram-positive and aerobic, but smaller and devoid of flagella and spores. The parasitic *Neisseria* are aerobic, but Gram-variable or negative; and the *Veillonella*, in addition to these characters, are anaerobic and very small indeed.

(*B*) The free-living streptomyces are large and strongly Gram-positive; they are aerobic and they branch and sporulate very freely. The large oral leptotrichia are aerobic and Gram-positive; they branch freely and form very occasional chains of spores[1]. The classical type of *Leptotrichia buccalis* is microaerophilic and Gram-variable; it branches rather rarely and does not appear to form spores[1]. Fusobacteria resemble *L. buccalis* very closely in general morphology, but are very small, Gram-negative, anaerobic and do not branch. All the last three are obligate parasites, but they are progressively more difficult to cultivate, in the order given. The origin of the anaerobic, Gram-negative *Bacteroides*, which bears some resemblance to the fusobacteria, is probably similar.

(*C*) The true *Actinomyces* (a genus of oral parasites typified by *A. bovis*) resemble *Micromonospora* in their main morphological features, but are anaerobic or microaerophilic and structurally degenerate[2].

If the conclusions arising from these observations are valid, it would appear that the great majority of parasitic bacteria of the Gram-positive group are descended from more complex, free-living ancestors This is, of course, a biological commonplace, but systematic bacteriology has not yet fully recovered from the effects of placing a very undue emphasis upon the taxonomic characters of those common pathogens, usually members of parasitic genera, with which the majority of bacteriologists are, or previously were, most closely acquainted, without taking into consideration the possibility of such tendencies as have just been described

The suggestion that structurally complex Actinomycetes are ancestral to simpler forms, and even to cocci, is not new[4] , but former hypotheses of this type have tended to suggest the sort of relationship that exists between the mycelial and oidial fungi, rather than a progressive degeneration of structure, associated with anaerobiosis or loss of Gram-positivity, and sometimes with both

It is not, however, easy to understand how these bacteria are able to dispense with the production of catalase and of the nucleic acids of the Gram-complex[3], which appear to be essential, or very advantageous, to their free-living counterparts In the case of the bowel-dwelling forms, it is possible that their environment protects them against free oxygen , but whereas neither *Clostridium*, *Bacteroides*, '*Lactobacillus bifidus*' nor *Streptococcus faecalis* produces catalase, the truly Gram-negative intestinal bacteria do so in every case Nor is the alternative explanation, that the anaerobes of the mouth, for example, live in such close association with large numbers of other bacteria as to profit from their catalase production or oxygen utilization, any more satisfactory, since the oral flora consists very largely of anaerobes or non-catalase-producing aerobes, such as streptococci and lactobacilli The animal tissues themselves are the only probable source of the enzyme

The significance of the loss of the Gram-complex in so many parasites is almost beyond speculation, but it is at least possible that it indicates the availability, in an elaborate form, of nutrients, with the synthesis of which from simpler materials these nucleic acids are concerned, under less-favourable conditions

DEVELOPMENT OF *TRYPANOSOMA VIVAX* TO THE INFECTIVE STAGE IN TSETSE FLY TISSUE CULTURE

By Dr WILLIAM TRAGER
Rockefeller Institute, New York 21

EARLY in the work on trypanosome diseases of man and animals in Africa, it was found[1] that cultures of trypanosomes could be obtained quite readily in blood agar media inoculated with infected blood and incubated at temperatures of 25–30° C But at the same time came the disturbing finding that such cultures lost their infectivity as soon as they began to grow[1,2] What was happening soon became clear in the cultures there developed only the so-called midgut forms of the trypanosomes, the same forms which develop in the midgut of an infected tsetse fly and which Bruce[3] had shown to be non-infective to the mammalian host In a suitable tsetse fly, however, the trypanosomes migrate to the salivary glands and proboscis, where they become transformed into infective forms[4] Recently, Weinman[5] reported in a preliminary way that he had produced infection in mice with two cultures of *Trypanosoma rhodesiense* maintained in a medium with trehalose (concentration not stated) With this exception, infective forms of the African trypanosomes have not previously been obtained in culture It seemed possible that these metacyclic forms might develop *in vitro* in the presence of surviving or growing tsetse fly tissue

The gonads of female lepidopterous larvæ are the only insect tissue that has up to now given outgrowths of cells at all comparable to those obtained with vertebrate tissues[6–8] Although mosquito tissues survived *in vitro* sufficiently well to support the growth of western equine encephalitis virus[9], they did not produce cellular outgrowths, nor have such outgrowths been obtained with tissue from other dipterous insects The cultivation of tsetse fly tissue was therefore a problem of considerable intrinsic interest, quite apart from its bearing on the developmental cycle of trypanosomes It is the purpose of the present brief report, however, to relate only the main results of the experiments dealing with the production of infective trypanosomes *in vitro* The complete details of these experiments, together with full information on the tsetse fly tissue cultures, will be reported elsewhere

Tissues of the fly *Glossina palpalis* were obtained from pupæ or young adults free from extraneous bacteria Pupæ of known age (sent to me from the Kaduna Laboratory of the West African Institute for Trypanosomiasis Research through the kindness of Mr W MacDonald) were sterilized externally in White's solution (mercuric chloride, 0 25 gm , sodium chloride, 6 5 gm , hydrochloric acid, 1 25 ml , ethanol, 250 ml ; distilled water, 750 ml), rinsed in sterile water and dried on sterile filter paper in a Petri dish Such pupæ, if kept for the required time in sterile vials with sand, produced bacteria-free adults The pupæ or adults were dissected aseptically in a drop of culture medium Fragments of tissues were explanted either in hanging drops or in a thin layer of fluid (0 3 ml) on the bottom of a Porter flask closed with a silicone rubber stopper

The culture medium (Table 1) supported initial outgrowths from, and differentiation of, several kinds of tsetse fly tissue In one type of outgrowth, mitotic division of the cells was seen To obtain cultures of trypanosomes, however, tissues were used which lived *in vitro* but showed limited or no outgrowth These tissues were the alimentary tract and salivary glands of a late pupa or a newly emerged fly To a

Table 1 PREPARATION OF THE CULTURE MEDIUM

*Solution A**	mgm /100 ml
NaCl	90

Yeast extract ('Difco')	200

* Based in part on work of Wyatt (ref 7) and Grace (ref 8)

Ingredients were dissolved in water redistilled in a 'Pyrex' glass still *p*H was adjusted to 6 8 with 1 0 *N* NaOH The solution sterilized through a 'Selas' 03 porcelain filter

Solution B†	mgm /10 ml
Reduced glutathione	200
Ascorbic acid	2

† Sterilized through ultrafine glass filter

Final mixture Mix 8 ml of solution *A*, 2 ml sheep serum, 0 5 ml solution *B*

In 1 ml of the above mixture in a centrifuge tube, crush gently two sterilized 12-day-old pupæ of *G palpalis* Centrifuge 15 min at 2,000 r p m The supernatant with the re-suspended fatty layer at the surface constitutes the culture medium

hanging-drop culture was added a minute drop of blood or trypanosome concentrate from an infected animal Continuous culture was achieved of all three species of trypanosomes tried *Trypanosoma brucei*, *T congolense* and *T vivax*

The most interesting results were obtained with *T vivax*, a species never before cultured and which, in the tsetse fly, omits the midgut phase and develops directly to the infective forms in the proboscis A first attempt at cultivation of this species in fly tissue culture, using washed trypanosomes from a heavily infected sheep, gave a negative result In the second attempt, the only sheep showing trypanosomes on that day was one, infected by fly-bite nine months previously, which had survived the acute infection and now occasionally showed small numbers of organisms in the peripheral blood A concentrate from this blood, in which only one trypanosome could be seen per low-power field, was inoculated to fly tissue cultures prepared two days previously Two days later it was noticed that the temperature of the incubator (set for 28° C) had gone up to 30° C At this time large syncytial multiplying forms of trypanosomes were seen in the tissue cultures From these a strain was established and maintained in tissue culture for three months It was discontinued only because the work was brought to a close Soon after its establishment the strain was successfully transferred to blood agar slants and is still being maintained in this way Later experiments then showed that *T vivax* could be started in culture only by following the conditions which had occurred quite fortuitously the first time, that is, using blood from the sheep with a long-standing chronic infection, inoculating the concentrate of trypanosomes to tissue cultures two days old, and—very important—incubating these at 30–32° C, not at 27–29° C Once started, the cultures can be kept equally well at either the lower or the higher temperature, but they have mostly been kept at the higher temperature

Four strains of *T vivax* in tissue culture have been begun, three from the original sheep and a fourth from a new infection in a sheep inoculated with blood from the original sheep The first two culture strains have been studied in some detail There were present in the cultures numerous forms morphologically indistinguishable from the classical infective forms of *T vivax* as seen in the proboscis of the tsetse But five sheep inoculated repeatedly with such material and followed for more than a month failed to show trypanosomes in the blood Two of the sheep did have a fever, one on the eighth and the other on the ninth day after intravenous inoculation of culture material, but no trypanosomes could be found

It was then decided to test the ability of the trypanosomes in fly tissue cultures to survive at body temperature, which is lethal to the usual culture of trypanosomes on blood media A three-day-old hanging-drop subculture of strain 2 of *T vivax*, in culture for six weeks, was placed in a jar immersed in a water-bath at 38° C On the following day the culture presented a mass of very active trypanosomes The material was inoculated intravenously into a sheep Exactly one week later, scanty trypanosomes were present in the blood of this sheep They were readily identified as *T vivax* The sheep was positive again on the following day, with about three trypanosomes per field This sheep first showed fever (105° F) on the ninth day, the only day of fever it has had At this time no trypanosomes could be found, and it has since remained negative except for the thirteenth day (1 trypanosome in 150 fields) and the eighteenth day (1 trypanosome in 40 fields) Thus, transmission from culture was accomplished

Attempts at repetition of this success were immediately instituted An interesting finding was that whereas some tissue cultures of *T vivax* showed mostly dead or sluggish organisms after exposure to 38° C, others were very active, like the culture which produced infection A clean sheep raised at the laboratory was inoculated with a culture of *T vivax* which had numerous active trypanosomes after the one day at 38° C This sheep showed a positive blood film and had a fever on the seventh day after inoculation

These two successful transmissions from culture make it certain that a reproducible method is now to hand for obtaining infective *T vivax in vitro* This makes possible a detailed study of the factors responsible for the acquisition of the infective state by trypanosomes, a matter of significance far beyond its immediate application in the field of trypanosomiasis The relatively light infections which seem to have followed the inoculation of cultured *T vivax* suggest the possibility of the development of a practical method for immunization against the parasite, using attenuated but infective cultures This possibility requires and deserves much further investigation

The work summarized in the foregoing report was done while I was a visiting investigator at the West African Institute for Trypanosomiasis Research, and I thank Dr T A M Nash, director of the Institute, and Dr R S Desowitz, in charge of protozoology there, for their kind invitation to work in their laboratories and for the facilities extended to me by them and their staff Travel to Africa was made possible by a grant from the Rockefeller Foundation

GEOPHYSICS

Disturbance in the Ionospheric *F*-Region following the Johnston Island Nuclear Explosion

According to the newspaper reports, American scientists exploded hydrogen bombs near Johnston Island on August 1 and 12, 1958, at heights of 160 km and 100 km The Apia magnetic records (Lawrie, J A, and Gerard, V B, private communication) give times as 10 50 and 10 30 G M T Some geophysical aspects of these explosions have been discussed by Cullington[1] and Kellog *et al* [2]

Here we will describe one of the effects on the ionospheric *F*-region We have 10-min recordings over the period of the first event and 2-min recordings over the period of the second event

Prior to both events, ionograms at Rarotonga showed the normal undisturbed night *F*-region On August 1, the ionograms 40 min after explosion (zero plus 40 min) showed a great increase in maximum electron density, and 10 min later this had exceeded the recording limit of the machine In the next 40 min the electron density decreased rapidly and at zero plus one hundred there was no trace of the normal *F*-region, but above it at a base height of 560 km was seen a layer the maximum electron density of which was roughly one quarter of the normal *F*-value The increase at the maximum phase was to at least seven times normal Another interesting characteristic was the gradual drop of fifty kilometres in height as the ionization decayed Fig 1 is a schematic diagram deduced from the ionograms

On August 12, the disturbance in the *F*-region took longer to reach Rarotonga and was much less severe A detailed true height analysis of these records confirmed the form deduced for the first event and ensured that no significant phases were missed We will discuss only the first event

In order to gain a better picture of the physical process we examined also the ionograms for Christchurch, 44° S, and Campbell Island, 53° S, and, through the courtesy of J A Lawrie and V B Gerard, the magnetic vectors which they had prepared for Honolulu, Palmyra Island, Fanning Island, Jarvis Island and Apia

A characteristic movement among the magnetic vectors was identified with the passage of the *F*-region disturbance The times of passage of the disturbance at the eight stations were then plotted against distance from the point of explosion (see Figure 2 *A*) The points lie well on the smooth curve except for Jarvis This Station is on the dip equator, and there is reason for supposing that the time of its vector is advanced by several minutes. The corresponding velocities are shown in Fig 2 *B*, values are only approximate because of limited data and time resolution

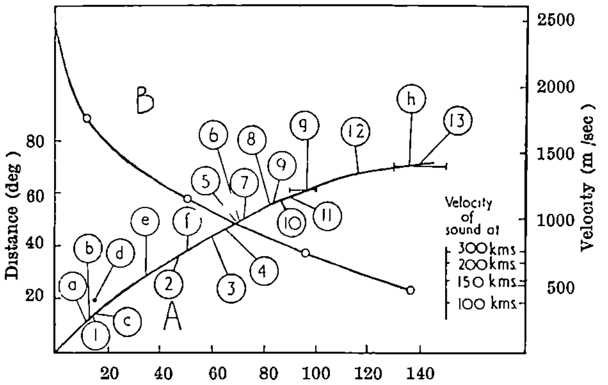

Fig 2 *A*, Curve of delay times versus distance in degrees *Observation sites* *a*, Palmyra Island, *b*, Honolulu, *c*, Fanning Island, *d*, Jarvis Island, *e*, Apia, *f*, Rarotonga, *g*, Christchurch, *h*, Campbell Island *Places where observations possible* 1, Maui, 2, Adak, 3, Guam, 4, San Francisco, 5, Kokubunji, 6, Akita, 7, Wakkanai, 8, Townsville, 9, Yamagawa, 10, Brisbane, 11, Okinawa, 12, Baguio, 13, Hobart *B*, Deduced velocity curve

The assumption made in drawing this smooth curve is that the velocity of propagation is independent of direction relative to the Earth's magnetic field Attempts were made to reconcile the time delays with a field-dependent velocity but no reasonable pattern emerged It seems, then, that the ionospheric disturbance is a by-product of a gaseous wave which is propagated at a velocity considerably above that of sound For convenience we will refer to it as a shock wave

It is not possible to account for the high value of electron density and its spatial distribution over Rarotonga merely by compression or even by the collection of all the electrons between Johnston Island and Rarotonga Restraint by the Earth's magnetic field of the motion of charged particles precludes electrons coming from the nuclear event itself Together with the complete disappearance of electrons after the disturbance, and the general appearance of the ionograms, these facts indicate electron production in the disturbance We postulate ionization by collision and subsequent removal by

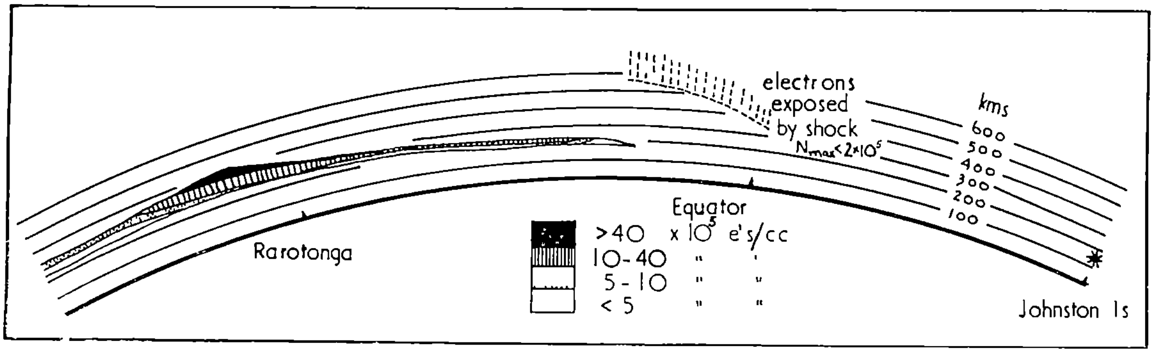

Fig 1 The spatial form of the ionospheric disturbance as deduced from the Rarotonga ionograms for the event of August 1

attachment or re-combination in a region of relatively high gas pressure

However, it does not seem possible that the main body of the gaseous shock wave travels in the region where the ionospheric disturbance is observed (200–550 km height), for the compression ratios of a shock wave of this velocity are insufficient to produce the observed ionization, and, moreover, there is not enough gas at this level to explain the extended front The apparent velocity at Campbell Island is below the velocity of sound at F-region height, while the characteristic form of the disturbance is maintained (increase in electron density with subsequent decrease in both density and height—no complete electron removal at this distance) Instead of a simple shock, we seem to have a supersonic surface wave of vertical extent much less than the wave-length, and the very high compression ratios producing the observed ionization are on its upper boundary We do not feel competent at present to discuss this wave further

As will be seen from Fig 2 *A*, many ionospheric stations are in regions where they may have recorded the characteristic movements associated with the wave Here is an ideal opportunity for international co-operation in an important study on atmospheric properties

This work will be reported more fully in the *N Z Journal of Geology and Geophysics*

Geomagnetic and Ionospheric Phenomena associated with Nuclear Explosions

NUCLEAR explosions at high altitudes were carried out at Johnston Island (geographically 16 7° N , 169 4° W , geomagnetically 14 3° N , 256 5° E) at 10 50 G M T on August 1 and at 10 30 G M T on August 12, 1958[1] Auroræ associated with these explosions were observed on both days at Honolulu[2] and Apia[3] Apia auroræ on August 1 have been discussed by Cullington[3], Fowler *et al*[4], Kellogg *et al*[5] and Elliot *et al*[6] In this communication geomagnetic and ionospheric effects associated with these events are described from the International Geophysical Year obtained at various stations in the Pacific area and the American continent

Immediately after the explosions, magnetograms showed sudden unusual variations at five stations in the central Pacific—Honolulu, Palmyra Island, Fanning Island, Jarvis Island and Apia The variation at Honolulu had the form of an intense bay disturbance The variation at the other four stations was somewhat like an unusually short-period magnetic storm (about 1 hr) with a sudden commencement Moreover, the sudden commencement at Apia showed an initial short reverse impulse (SSC^{*}) as reported by Cullington[3] These geomagnetic effects occurred similarly for both events, although the magnetic storm on August 12 was smaller than that on August 1, probably due to the lower explosion height

These associated geomagnetic storms indicated that counterclockwise circular electric currents were formed in the vicinity of Johnston Island immediately after the explosion, due to the dynamo effect caused by winds of charged particles which moved radially outward from the centre of the explosion In other words, if the wind velocity due to the explosion in the 80–100 km level became of the order of 100 m /s and the electrical conductivity increased by the order of 10 times due to high-energy particles and X-rays, the associated counterclockwise electric currents in the vicinity of Johnston Island would have been sufficient to give the observed magnetic variations even at places 1,300–2,200 km distant, such as Honolulu, Palmyra, Fanning and Jarvis Islands The geomagnetic effects observed at Apia could have resulted from these circular electric currents and an increase of the electrical conductivities in the 80–100 km level caused by β-decay electrons coming along magnetic lines of force from Johnston Island

The maximum geomagnetic change at Honolulu occurred around the time at which a shock wave from the explosion arrived at Maui, as mentioned below It is possible, therefore, that there was an additional effect increasing the intensity of the electric currents just at the moment when the shock wave hit This could have been caused by a dynamo effect resulting from the shock wave

At the Maui Ionospheric Station in the Hawaiian Islands a sudden increase of $f_{\min}$ (the minimum frequency of the observed radio echo) was observed at 10 50 22 ± 7 G M T on August 1 lasting several minutes, and again at 10 30 37 ± 7 G M T on August 12 for a few minutes These changes were similar to a solar flare effect However, since they occurred during local night, they must have resulted from the explosions Probably they were caused by ionization in the D-region by X-rays from the blasts

On August 1 a peculiar oblique echo began at Maui 13 min after the explosion and lasted until 11 12 G M T , when it was completely blanketed by increased ionization in the D-region This phenomenon may have been due to a shock wave caused by the explosion A no-echo phenomenon, called a 'blackout', began at 11 12 37 ± 7 G M T , about 22 min after the explosion, and continued until 13 20 G M T During this time a faint F-echo occasionally appeared After 13 20 G M T the $F2$-layer gradually appeared and recovered to normal

At Maui, between 10 56 G M T and 10 59 G M T on August 12, both the height and the critical frequency of the F-layer decreased abruptly At 11 03 G M T a stratification appeared in the F-layer and showed an unusual sequence of changes This sequence indicates that an irregular ionization in the F-layer, caused by a shock wave from the explosion, was propagated horizontally over Maui from the direction of Johnston Island The estimated speed of the shock wave is about 0 9 km /s for this event, and 1 3 km /s for the event on August 1 The wave motion created repeated irregular ionizations in the F-layer until a blanketing occurred A blackout occurred at 16 00 G M T , 5 hr 30 min after the explosion, and lasted 2 hr Even after that time there was severe absorption until 5 00 G M T on August 13 The behaviour of the ionospheric storm of August 12 was in general similar to the ionospheric storm of August 1 On August 12, however, the onset of the blackout was slower and the duration of the radio-wave absorption was much longer, in spite of a smaller geomagnetic effect The lower explosion height and the daytime onset of the blackout on August 12 may have been responsible for these differences

Rarotonga also showed explosion effects in the ionosphere for both events However, other ionospheric stations—Adak, San Francisco, Washington, White Sands, Huancayo, Godley Head and Okinawa —did not show any certain explosion effects Accordingly, it is concluded that direct-explosion effects on the ionosphere and the geomagnetic field occurred over an area in the central Pacific, roughly the region 170° E-150° W and 40° N-22° S Radio signals from Honolulu (10 and 15 Mc/s) and from San Francisco (13 75 Mc/s) received in Japan showed sudden drops[7] after both explosions These were due to radio absorption in that central Pacific region

From the present study of these geomagnetic and ionospheric effects, the explosion height is estimated as 70–80 km on August 1, and about 40 km on August 12, although the *New York Times* simply reported it as 100 miles on August 1 and lower than that on August 12

In addition, three other nuclear explosions that occurred in the south Atlantic on August 27, 30 and September 6, 1958, at about the 480-km level, were considered No remarkable geomagnetic and ionospheric effects directly associated with these blasts could be detected in the normal magnetograms or ionograms

Full details of this work will be published in the *Journal of Geophysical Research* I wish to express my thanks to Dr W O Roberts and Mr A H Shapley for their kind help, and to Mr D B Bucknam for his considerable assistance I am also grateful to the Boulder Laboratories of the National Bureau of Standards for an appointment as guest worker and for extending to me their facilities I wish to thank the International Geophysical Year Data Centers *A* for Geomagnetism and the Ionosphere for the use of data This study was supported by the National Academy of Sciences as part of the International Geophysical Year Programme with assistance from the Ford Foundation

Magnetic Effects Resulting from Two High-Altitude Nuclear Explosions

ON August 1 and 12, 1958 two nuclear devices were exploded in the upper atmosphere above Johnston Island in the North Pacific No exact information is available to us regarding the heights of the explosions, but it is believed that the first explosion was higher than the second Unusual magnetic effects, mentioned previously by Cullington[1], were recorded after both explosions on magnetographs at Honolulu, Palmyra Island, Fanning Island, Jarvis Island and Apia Fig 1 shows the location of these observatories

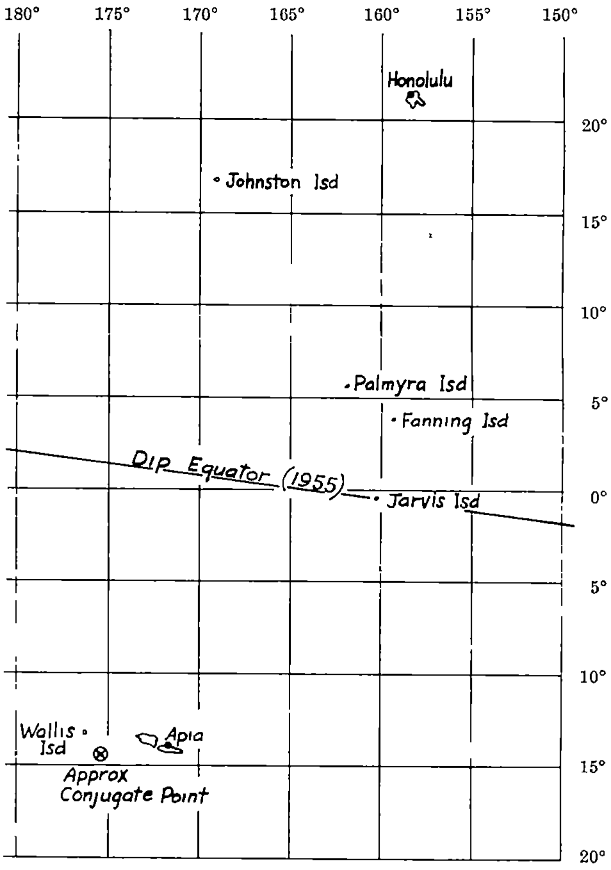

Fig 1 The region of the Pacific showing islands where unusual magnetic effects were recorded

Vector diagrams of the variations in a horizontal plane are shown in Fig 2*a* and *b* Fig 2*a* refers to the first explosion, and Fig 2*b* to the second The effects at Palmyra, Fanning and Jarvis are very similar, and only the Jarvis Island diagram is presented here Variations in a vertical plane are not illustrated, since the only important effect they reveal is a marked downwards movement in Z at Apia at about 10 55 G M T, following the second explosion

An examination of these diagrams has led us to classify the effects into four phases—initial, second, main and final, as labelled in Fig 2*a* and *b*

We suggest the following broad interpretations

Initial phase A hydromagnetic impulse affected by dispersion, corresponding to the Alfvén wave postulated by Kellog *et al* [2]

The front edge travels faster than 10^8 cm/sec and the time of the maximum corresponds to the speed of a transverse hydromagnetic wave of frequency 1 c/s travelling parallel to the magnetic field[3] Across the lines of force, the impulse travels at about the same speed, but suffers greater damping

Second phase Produced basically by the transport of individual β-particles[4], photoelectric and Compton electrons, and possibly ions along the line of force from above the point of the explosion to the conjugate point

As the shock wave and fireball move upwards, more and more individual charged particles can make their escape Radioactive decay of escaping high-energy neutrons probably broadens the region over which the transport occurs

As well as those magnetic fields due directly to the travelling particles, dynamo effects are caused by

BRITISH ASSOCIATION MEETING IN YORK

THE PROPER STUDY OF MANKIND IS MAN*

By SIR JAMES GRAY, C.B.E., F.R.S.
President of the British Association

I

IN the public mind, scientists are largely associated with the study of physical systems and practical problems; they are not directly concerned with moral principles nor are they responsible for the social repercussions of their discoveries. But it is impossible to be a scientist without being a human being and recognizing that social life depends as much on moral principles as on scientific knowledge. So far as science is mainly concerned with our material environment, it tends to isolate itself from the main factors which determine human behaviour. So far as the humanities are mainly concerned with Man's reactions to past environments, we cannot be quite sure how far their judgments are relevant to modern life. Such limitations will not be overcome by keeping our own particular type of knowledge in a water-tight compartment; the sciences and humanities should seek common ground. Hence the title of this address.

During the course of years, the need for a wider social outlook in science has been reflected by two important extensions in the range of the British Association's interests. It now includes the social as well as the natural and mechanical sciences, and it is more and more concerned with the dissemination of scientific knowledge to the whole community. But the wider the field and the larger the audience, the more difficult the task of presentation becomes. Scientists find it more and more difficult to keep abreast of all the main lines of development within their own subject, and almost impossible to know what is happening in other fields; we become more and more specialized and less and less able to see the wood for the trees. It might be said that one of the Association's most important functions is to bridge the gap between its different sections. In addressing the Association, its president has to decide whether he should speak as a specialist and make little or no attempt to relate his theme to wider issues, or whether to stray into unfamiliar fields, and run the risk of scientific, economic or political criticism[1]. Perhaps rashly, I have chosen to face these dangers, by trying to look at man from a biological point of view and to suggest how the picture might—here and there—merge into a wider background. But before doing so, I would like to touch on two quite general topics.

First, one of the most important social aspects of modern science is its repercussion on international relationships. Here there will always be potential danger and waste of human effort until individual nations can be persuaded to think in terms of the welfare of humanity as a whole. A scientific approach to such problems must be one of dispassionate analysis, but we shall not make much impression on public opinion so long as men's minds are biased by fear and suspicion; frightened or angry politicians, like frightened or angry animals, cannot be trusted to react wisely. There is not the slightest doubt, however, that the discoveries of physics *have* frightened mankind and that there are far too many intelligent people looking askance at science and wondering where it is leading them. In trying to link the sciences to the humanities our primary objective should be to depict man's position in the world of Nature as a source, not of fear or doubt, but of courage and inspiration. Our second main objective should be to demonstrate the place of science in a general philosophy of life. To be of real value, such a philosophy must rest on knowledge and experience which have already proved acceptable over a very wide range of local environments and national interests, and it must, at the same time, be closely concerned with problems of everyday life. In these respects science is unique. Except so far as they are subject to political restraint, scientists of all nations co-operate in solving Nature's jig-saw puzzles, and as Prof. A. V. Hill said at Belfast[2], "The fundamental principle of scientific work is the unbending integrity of thought, following the evidence of fact wherever it may lead within the limits of experimental error and honest mistake". This attitude of mind is not peculiar to scientists; it is common to all who have a respect for the truth. But in the fields of law, language, history, literature and, above all, politics, our general outlook and our individual range of knowledge depend to a very dangerous extent on local environment and national tradition. By freedom from such limitations science provides ground—perhaps the most solid ground—on which to base a wider range of co-operative effort. But the gap between a scientific and a humanitarian outlook cannot be bridged by the statistical laws of physics and chemistry; we are forced to apply the less precise, but not necessarily less important, principles to be derived from the world of living organisms. The challenge is, therefore, to the biological sciences, especially those which deal, at the borderline of sociology, with the behaviour of organisms and their relationship to their environment. Can they yield broad principles which are applicable to man, or must scientists be content to see the law of the jungle take its course except in so far as it can be restrained by humanitarian effort? The answers to such questions may well decide how far science can claim to be of direct cultural significance.

* Presidential address delivered in York on September 2 and appearing in the September issue of *The Advancement of Science*.

II

Man's position in the world of Nature is brought most sharply into focus by the concept of natural evolution. Cosmic, biological and human evolution can be regarded as phases in a continuous natural process—and, from this point of view, astronomy, geology, biology, archæology and history form a continuous spectrum of knowledge. To pass from a primeval nebula to a modern man without any sudden break in continuity of thought gives a feeling of intellectual tidiness, but quite apart from this it helps us to visualize man against the background of his past and to regard him as Nature's supreme masterpiece. At the same time, he must not get *too* big for his biological boots or tend to exaggerate the gap between himself and the rest of the animal kingdom. No animal can manufacture aeroplanes, Asdic or radar; but the prize for aeronautics must go to the shearwater which navigated the Atlantic without compass or chart while Asdic has an extremely efficient prototype in the vocal cords and ears of bats. By surrounding themselves with an electric field, some fish (for example, *Gymnarchus*) can—in total darkness—detect foreign objects in the surrounding water with very remarkable precision. The weight of the mechanism involved—including the animal's brain—amounts only to a few grams; a man-made instrument of comparable performance would involve at least a ton of highly complex electronic machinery. In fact, as delicate and precise pieces of machinery, man's inventions have not yet reached the standards of those produced during the natural course of biological evolution. No laboratory in the world can compete with the biochemical skill of even the smallest living organism. On the other hand, man can claim that within a few centuries he has produced things for which Nature required many millions of years; but we need not feel in the least ashamed of the older members of our evolutionary family: we have still a great deal to learn from them.

To visualize man's position in the animal world, it may be useful to define his main diagnostic characters. He is a highly gregarious bipedal mammal with unspecialized limbs but a very large brain. He is the only animal which has developed the symbolisms of speech and writing and he may well be the only animal capable of rational thought. He is, therefore, the only organism which can hand on patterns of acquired learning from one generation to another. To these advantages he owes his dominant position in the world to-day. They have enabled him to exploit his environment and increase his numbers and range of distribution far more quickly and far more extensively than any animal of comparable size. He has eliminated some of his competitors and exploited others for his own use, but the time has now come when different races of men are competing with each other within the closed arena of a limited environment, and it is not easy to see where it will end. There is nothing equivalent to this in the inanimate world; but, when a biologist looks at the general trend of events, he is inclined to say, "Where have I seen something like this before, what is it due to, and how does it *usually* end?"

Of the many points of view from which biologists can study man, three are of particular social interest. First, what is the relationship between the size of a human population and the resources of its environment? Secondly, what are the factors which influence man's ability to acquire new patterns of behaviour? Thirdly, what is the significance of the gregarious habit?

One of the first attempts to subject social problems to biological analysis was made by Malthus in 1789 when he forecast the fate of a nation the rate of increase of which was greater than that of the resources of its environment. Malthus did not say that war, pestilence and famine were inevitable; he said that they were inevitable unless people, by voluntary control, reduced their rate of reproduction. The theory of animal evolution by natural selection, enunciated just a hundred years ago by Darwin and Wallace, involves the principle of over-population and introduces the concept of randomly produced mutations. Some of these increase an individual's chance of survival whereas others decrease it; those which best adapt the animal to the conditions of life imposed by the environment survive, the rest are eliminated. The course of animal evolution is not directed by the organism itself, but by the external environment; the animal throws the dice but the environment decides the winning numbers. A persistent struggle within an over-populated environment is an essential condition for evolution by means of natural selection; it is the price which Nature demands for progress. There is no evidence that adaptations acquired during the life-time of an individual animal can be handed on to its offspring; each generation has to take an environment as it finds it and make its own way in the world. There is also the danger of over-specialization; a species which has become very highly adapted to a particular environment may be extremely vulnerable if the environment changes relatively suddenly. The course of human evolution is entirely different. Speech and writing enable each generation to modify and control its environment in the light of experience gained by its predecessors and to hand on acquired benefits without bodily specialization. As soon as man learns to discipline himself to the fact that his environment is world-wide, he can begin to direct the course of his own evolution without the discomforts of over-population. If he fails to realize his powers and allows things to drift, his future seems dark; if he really bestirs himself, there is much less need to be afraid.

Quite apart from any evolutionary significance, there can be no doubt about the validity of Malthus' argument. Western Europe and North America have followed his advice; but, as stressed by Prof. P. M. S. Blackett[3], the density of population in other parts of the world is far higher than can be adequately sustained by the environment. We can, of course, shrug our biological shoulders and say that different races of men live in different environments and are, therefore, subjected to different intensities of struggle, and it would be comforting if we could be quite certain that it is always the fittest which survive. We cannot salve our consciences quite so easily nor will *we* escape for very long from environmental pressure. Our own population may remain relatively stable, but our environment expands with almost every new major scientific discovery, and the greater the overlap of the environments of different nations the fiercer is the competition. The result is substantially the same as that of an expanding animal population within a limited environment. These problems lie within the field of Section *F* (Economics), but they are fundamentally similar to those which arise in animal ecology; it seems just as unrealistic to regard one race of man as an isolated unit as to study the population of one member of a biological food-chain without reference to those of all the others The writing on the wall is tolerably clear, if man behaves like an animal and allows his population to increase while each nation steadily increases the complexity and range of its environment, Nature will take her course and the law of the jungle prevail

To see this law in action, it is useful to remember that Nature has made, not one but two, great experiments in the design of social animals The first was carried out in Mesozoic times when man's mammalian ancestors were beginning to emerge from reptiles The results of this experiment are represented to-day by the social insects—notably the ants There are a very large number of different species of ants none of which interbreed, among them is found a range of complexity of social behaviour which is not only unique in the animal kingdom but which also forms a very remarkable parallel to different races of human beings At one extreme are species forming small communities, restricted to localized or specialized environments and exhibiting relatively little sub-division of labour between individuals At the other extreme are large and often aggressive communities with marked differentiation of structure between different grades of individuals, populations of this type display high levels of co-operative effort involving, in some cases, the rudiments of agriculture and husbandry In all cases, however, ant societies are organized on a straightforward totalitarian basis, for the contribution made by each individual towards the welfare of the community is determined from the time of birth, each grade of individual is structurally adapted for predetermined tasks How far ants can communicate with each other may be doubtful, but it is tolerably certain that members of the same community recognize each other by a characteristic smell, and as the brain of an ant is about the size of the head of a pin, it is perhaps not surprising that ants should attack or kill an individual from another colony with a smell slightly different to their own It is much less easy to understand why a man, with a brain of an entirely different order of complexity should, at times, react almost equally violently to skin pigments slightly different to his own

But it is not only in respect to individual relationships that the study of ants is relevant to man Ants are the only organisms which—apart from man—indulge in organized warfare, raiding the nests of other species and incorporating captives into their own society But perhaps the most striking facts relate to species which have changed their habits and distribution within recent times Two instances of territorial expansion are known to have occurred in the past 150 years[4] Early in the nineteenth century an Eastern species (*Pheidole megacephala*), having spread rapidly over North Africa and South Europe, managed to reach the islands of Madeira and Bermuda, in both places it exterminated the smaller native races Meanwhile, a similar policy had been carried out by another species (*Iridomyrmex humilis*) from the Argentine which, having landed at New Orleans, very rapidly overran the southern United States, in due course it too reached Bermuda, where it proceeded to eliminate *Pheidole* In the world of ants there is no place for small peaceful communities unless they can isolate themselves effectively from larger and more powerful neighbours, nor does there seem any lasting peace between large aggressive communities Solomon's advice has, I suspect, been misinterpreted It should read "Consider the ants, and, if you use your intelligence, you will see how *not* to deal with international problems'

Having designed the ants, Nature waited for about 150 million years before embarking on her second or human experiment She waited, in fact, until it could be carried out with a species in which an individual's contribution to society was no longer based on inherited structural characters but on the power of intercommunication with other individuals, in other words, until man's brain had reached a level of development which enabled him to control his environment, and to deal rationally with the subdivision of labour between individuals and with the distribution of natural resources between different groups of individuals At the same time she arranged that such groups should not be physiologically isolated from each other Different races of men can interbreed or they can, if they wish, come to mutual agreement about the distribution of world resources between different nations The first policy would seem to lead to a World State with uniformity of social pattern and of material interests, the second policy involves territorial limitations and economic agreements Both, as we know only too well, involve great practical difficulties All the same, men really ought to be able to do something better than ants

The second basis of comparison between man and animals concerns the factors which control his behaviour The past fifty years have produced a very great increase in our knowledge of animal behaviour and about the factors which control the acquisition of new patterns of response For present purposes, however, attention may be focused on two problems, the extent to which animals can profit from extraneous instruction, and the extent to which they are able to learn for themselves The first of these fields is explored by means of the conditioned reflex technique, whereby an animal learns to associate a specific visual, or other sensory, stimulus with forthcoming food or impending danger In order to establish this result it is necessary to conform with five basic principles, all of which have their counterpart in the training of human beings

(i) The response expected from the animal must not be unduly complex, the animal must be able to reach the food or escape the danger by making reasonably simple movements In other words, the problem must not be too difficult (ii) The lesson must be presented to the animal under conditions which ensure freedom from extraneous disturbance It will not learn if its attention is constantly diverted by other changes in its environment (iii) The problem must be presented to the animal on an adequate number of occasions, the more frequent the lesson, the fewer the mistakes become (iv) There must be an 'incentive' to learn—a 'reward' for success or a punishment for failure Further, the 'reward' must be related to the needs of the animal (v) Finally, the experimenter must possess adequate skill and patience The ability of an animal to learn depends to a very large extent on the personality and enthusiasm of the teacher

These five principles apply equally well to the education of human beings if we make suitable allowances for increase in complexity of the lesson to be learned and in the nature of the incentive to learn But we can go a little further for, as with men, different individuals of the same animal species learn at very different rates On the other hand, there does not seem to be any clear correlation between an animal's ability to learn and its position on the evolutionary tree It is possible to trace the structural evolution of the human brain through each of the main classes of vertebrate animals , the large paired hemispheres arose in the Devonian lung-fishes and the cerebral cortex in the early Permian reptiles It would be very convenient if step by step with an increase in size and complexity of the brain it were possible to trace a corresponding increase in complexity of behaviour and in ability to learn Unfortunately this is not the case , some fish, without hemispheres or cortex, exhibit behaviour patterns which seem just as complex as those of reptiles or even of some mammals In due course this difficulty will be resolved but for the time being one can only say that there seems to be one feature common to all species which learn easily, namely, a vivacious but not unduly excitable temperament—fish, rats, monkeys and children are all interested in their surroundings, they have a natural tendency to explore their environment and they are interested in anything new or strange , they are all, perhaps, potentially good scientific observers

But the value of the instruction given to human beings by a teacher is largely judged by the extent to which it enables a pupil to make use of his acquired knowledge and to go on to learn more by himself Within the animal world there is very little evidence to suggest that experience acquired from one pattern of environment or from one problem can be readily applied to subsequent ones of somewhat different nature An animal's own approach to a problem, like that of a very young child, is very largely one of random exploration , having found the solution by chance the number of ineffective responses on future occasions becomes less and less until the correct response is stabilized

How far animals display evidence of the higher levels of mental analysis associated with 'intelligence' in human beings is not too clear, for it is extremely difficult to subject intelligence to an agreed standard of measurement When judged by human standards, the I Q 's of all animals are, undoubtedly, very low , but it may be that we are not always setting *them* quite the right type of examination

Although it is difficult to detect an increasing capacity to learn with an increase in size and complexity of the brain throughout the main classes of vertebrates, it seems clear that there is a substantial increase in learning ability as soon as an animal's brain reaches a level of structural complexity comparable with that of man The young chimpanzee, like a human baby, is typically a friendly playful creature dependent on, and with an affection for, its mother But as it grows up, it begins to show marked signs of individuality , some become morose, unfriendly and vicious, others retain a friendly disposition towards their neighbours and a co-operative attitude towards human teachers The ability to respond to training shown by the latter type of individual is, of course, very remarkable , but when left to itself, a chimpanzee seems to rely on an initial process of trial and error Like many other mammals, it can give audible and visible signs of fear, anger or pain , but there is no evidence that a chimpanzee can make audible or visible signs which other individuals associate with specific material objects , the mental development of the adult ape seems roughly equivalent to that of a human baby before the latter has learnt to speak Nothing can disguise the enormous difference between an adult ape and an adult man in ability to learn and to control their environments, but it might be argued that a relative test of the brains of an adult ape and of an adult man, as computing instruments, should be conducted on the basis that neither pupil nor teacher should be allowed to speak, read or write , the gap between animals and men might narrow very appreciably

The third and perhaps most important biological aspect of man's behaviour concerns the gregarious habit Here again the distribution among vertebrate animals is curiously unrelated to their evolutionary history , it is well marked in certain species of fish, birds and mammals, but absent in others In some cases the existence of a herd or flock is clearly of survival value , a pack of wolves has a wider choice of food than an individual operating by itself But, it is not always clear why one species should be more gregarious than another to which it is closely related In the present state of knowledge, it may be safer to say that some animals are restless or uneasy unless in close proximity to individuals of the same species—that they have, in fact, a deep-rooted antipathy to isolation or loneliness The resultant grouping establishes the herd as a unit which responds as a whole to an external stimulus applied to one or a few individuals The response is most clearly defined when the stimulus evokes an emotional reaction of fear or anger in the individuals directly concerned, and one of the most distinctive features of herd behaviour is the speed at which these emotions spread throughout the community If certain individuals are more highly susceptible than others to external stimuli, the response of the group is determined by the most timorous or the most belligerent members of the community The majority of the herd subjugate their own individual behaviour to that of a few, and in the long run individuals benefit by greater security from predators or greater certainty of obtaining food If an individual is unduly insensitive to emotional stimulation by its neighbours, it is likely to be eliminated by natural selection—the sheep that walks by itself gets eaten and the solitary wolf may starve These principles were applied to the analysis of human behaviour by Wilfrid Trotter[5] In order to avoid physical or mental isolation, men are prepared to subjugate their own immediate needs or predilections to those of society as a whole Anti-social activity is kept in check by fear of intellectual or physical isolation , feelings of increased security and greater freedom from personal doubts and fears are set off against loss of individual freedom of action How far psychologists have developed or rejected Trotter's suggestions I do not know, but there can be little doubt that they opened up a useful biological approach to sociology by suggesting that our instinctive reaction to something new or strange is, as in animals, to conform with our neighbours, and that, at moments of crisis, it is better to follow a leader than rely on personal judgments These and allied problems belong to Section *J* (Psychology). All I wish to stress is that the phenomena of mass psychology in man, like other aspects of his behaviour, have their roots far down in his evolutionary history

Perhaps the most striking difference between the social habits of man and those of animals is the existence of a hierarchy or grading within human society Only in a very few cases does this appear to exist within the animal kingdom The nearest approach seems to occur in birds; a flock of jackdaws feeding in a restricted area resolves itself into a well-marked order of feeding priority. Lorentz has recently reported that if a high-ranking male decides to mate with a low-ranking female, the latter rises in social status and feeds with her husband; all this sounds reasonably familiar to human ears.

This is perhaps as far as a zoologist ought to go in trying to view mankind through biological spectacles. But one does not need to be a professional biologist to appreciate that the rates of change in the pattern of human behaviour and in the nature of our environment have, during the past five thousand years, been incomparably greater than those of any other organism at any period of its history; our clothes, houses, habits and social organization change with successive generations. In fact, if one were forced to select the organism which best displays the phenomenon of persistent evolution one would undoubtedly choose man. I have tried to show that the broad principles which relate the size of human populations to the resources of their environments and those which govern an individual's ability to learn from personal experience and so adapt himself to his environment are qualitatively similar to those which apply to animals. On the other hand, man is—as I have said—unique in that he is—or can be—the master and not the slave of his environment, and the story of his later evolution is told in terms of social and economic history.

In suggesting further points at which biological principles seem to be applicable to the evolution of human society a zoologist can only look towards Section *H* (Archæology and Anthropology) and hope that his spectacles are not completely out of focus. In its very early stages human society must have been organized into quite small units each dependent on the natural resources of a small circumscribed environment. The discovery of fire and development of agriculture must have increased the range of the environment and the optimum size of the population required for its exploitation, while the stability of the group would become more and more dependent on the maintenance of an effective sub-division of labour. The larger the population and the greater the degree of specialization the greater the limitations necessarily imposed on individual freedom of action. A new and very important integrating factor seems to have come into action when natural phenomena became linked with supernatural concepts—fear of isolation or reprisals from fellow-men being reinforced by fear of a superhuman agency and a sense of greater security inspired by reliance on supernatural support. Such beliefs had no material basis but they would be the cement which held society together and, as such, be of immense survival value. But it is difficult to avoid the conclusion that such beliefs, like scientific theories, must undergo change as man's knowledge increases and his environment alters. From this point of view, it is not easy to regard any one belief as an expression of absolute and unchanging truth. It may be argued that such things lie outside the orbit of the British Association; but if science is to be of direct cultural significance, it cannot shut itself off from one of the main factors which have influenced men's attitude to social problems. A recent issue of *Nature*[6] contained a leading article on the proceedings of the last Lambeth Conference; it must have been a very long time since an Archbishop of York addressed such a Conference in language which scientists could so readily understand. Against such a background, the sciences and the humanities ought to be able to find something in common.

III

It is easy to say that science should be welded to the humanities, but much less easy to suggest how this should be done. Each of us has different views according to his own particular interests. I confess that my own approach is based on personal experience. About fifty years ago I chose to specialize in biology, and from time to time I have been asked, "If you had known that you would spend a good deal of your later life studying the movements of animals, what subject apart from biology would you have read at school and at the University?" The answer is simple. I would have read physics, chemistry, mathematics and mechanical engineering. The moral is that no young scientist should be allowed to forget that new discoveries tend to arise from the borderland between different subjects where the discipline of one is applied to another. Had I appreciated this I would have been a much better biologist; but whether I would have been a better human being is another matter. If I am asked the 64-thousand dollar question, "Had you known that you would have had to adjust yourself to a rapidly changing and somewhat uneasy world, what additional training would you like to have had?" I think my answer would be that I would like to have been trained to think dispassionately about social and political affairs in the light of experience drawn from the past, and to have been taught to appreciate beautiful things. But could I have acquired this knowledge while training as a scientist? Perhaps not, but I still think that I could have been shown a wider picture. Having been taught to visualize the spectrum in terms of the wave-lengths of light, could not I have been encouraged to learn a little about colour as a source of æsthetic pleasure? Why did I learn about the properties of iron and carbon without reference to the industrial revolution? I might even have developed a taste for the classics if I had known that Aristotle had written a very good text-book of zoology. Perhaps I expected too much in hoping to appreciate an artist's view of Nature from the point of view of the scientist. But I am not completely convinced. A scientist's attitude towards his observations does not seem to me to be so very different from that of a poet towards his words or a painter towards his colours; isolated observations have no more value than single words; it is only when they fit into a satisfying pattern that the scientist feels he has achieved his end. This analogy may be unconvincing, and if it still seems difficult to combine the vision of the artist with the outlook of a scientist, I can only suggest that Leonardo da Vinci and Sir Christopher Wren seem to have had pretty good shots at it. It would be very interesting to know the sort of training they had in early life.

But a plea for a wider outlook in the teaching of science is nothing new. It was largely the background against which Section *L* (Education) came into being, and it was urged again and again by Sir Richard Gregory. Since then there has been much discussion and many reports. In 1933 the declared aim of the London County Council was that they "wished their pupils to obtain a broad view of nature, to study Mankind and his environment from various standpoints, more particularly from the point of view of both the biological and physical Sciences". In 1946 the Advisory Council for

Secondary Education in Scotland was even more explicit "During the earlier secondary years at least, the study of man in his world, like the study of science, is a unity which should not be broken by any sharp division into 'subjects' the theme must be one' Only last year (1958) a Committee of the Science Masters' Association urged that "The schools have the duty of presenting Science as part of our common cultural and humanistic heritage, it should be taught in harmony with and not in opposition to the various Arts subjects " It seems fair to assume that this is a goal towards which we would all wish to strive, but when we try to approach it the road proves extremely hard and most of us, in practice, fall by the wayside

We cannot shut our eyes to the fact that our national economy depends on our ability to make and exploit new scientific discoveries If we wish to maintain or extend our standards of material comfort, we must have more professional scientists and highly trained technicians, and we must be prepared to devote an adequate fraction of our educational effort to get them But highly trained specialists form only a very small proportion of the population, and we may be paying for them in very hard currency if we have to deny to a very much larger fraction of the community a reasonable chance of "seeing life steadily and as a whole" A democratic society has to decide how much of its total educational effort should be devoted to an ever-increasing standard of living, and how much to raising the intellectual standards whereby the majority of the population forms its judgments on matters which are susceptible to personal prejudice or political propaganda It is not easy to assess the factors which mould public opinion, but a recent inquiry sponsored by the Nuffield Foundation[7] and the B B C indicates relatively clearly that the attitude of mind of an individual towards a changing environment is directly related to the nature and extent of his full-time education and that it is this training which largely determines, in later life, his response to other potential sources of education—such as libraries and broadcasts If we wish to awaken a widespread interest in science, or—still more—wish to contribute toward the formation of an enlightened public opinion, we must sow our seeds in the schools and in organized centres of adult education In the latter field, the Area Organizations of the British Association are of fundamental importance as authoritative and coherent sources of information for an increasing fraction of the community By working with other organizations they can make a very definite impact not only on the scientific but also on all aspects of public opinion

But the key to the main problem lies in the schools, and the responsibility resting on school teachers can scarcely be exaggerated[8] Too many are asked to do two jobs at once—to provide a training for potential specialists, and at the same time give a training which will best equip the average boy or girl for later life If we are to pay more than lip service to the belief that a good all-round education is the best means of raising the intellectual level of the community, we must recognize that our most urgent need is for good general practitioners in the art of education Really inspired teachers working with adequate but simple equipment will achieve more for general education than specialists in highly equipped laboratories But the scales have been heavily weighted in favour of specialization Almost exclusively, our universities are producing specialists Some of these return to the schools, where they in turn teach on a specialized front So the spiral of specialization has gone on It is only natural that able teachers should get an intellectual stimulus by preparing boys and girls for scholarship examinations and so providing recruits for fields of research in which they themselves are interested, but it is by no means clear that their work is necessarily more important, or more difficult, than that of those whose primary object is to persuade people that they cannot live by bread alone If we really believe in general education, we must produce and encourage the right type of teacher No man or woman in their senses enters the school-teaching profession for financial gain, but a community which rates thirty inspired schoolteachers as equivalent to one high-grade comedian or film star may well deserve a very unhappy fate A benevolent dictator would make school-teaching the most highly respected and the most highly paid of all professions, and the Ministers of Education the most important officers of government, but, in both cases, he would demand a very high level of performance We must do the best we can without him

The value of an educational system can perhaps be judged by the extent to which it leaves people with a desire to know more about the world at large and a feeling that this can be satisfied, at least in part, by personal effort To meet a constantly changing environment the general pattern of teaching must be constantly under review If a curriculum is allowed to degenerate into a series of isolated subjects with little or no immediate bearing on everyday life, the result can, perhaps, best be described in words which I think the president of Section *L* (Education) will recognize "When far too many boys and girls will carry away from school little more than gobbets of ill-digested knowledge and a distaste for what has yielded so little"[9]

But, as I have said, it is easy to talk and to criticize, it is much harder to plan for action So far as science is concerned, the British Association might approach the problem of general education in the three familiar stages of research, development and production The first step would involve an assessment of the evidence · if the Association's judgment were given in favour of a wider, and perhaps more biological, outlook on education, it should do all it can to see that it is put into practice on a limited front and—in the light of experience—allowed to spread gradually into full-scale production All this would involve very far-reaching reorganization of schools and universities While Oxford and Cambridge shiver on the brink of optional Latin, the University College of North Staffordshire is swimming the Hellespont by insisting that all students should, during their first year, survey the whole field of knowledge as a coherent picture before proceeding in three subsequent years to specialized training This is, in my opinion, one of the most important and courageous educational experiments in our times for, if it succeeds, a great number of our major difficulties will be resolved

On the other hand, if 'general education' and 'general science' are condemned as 'smatterings of everything and a knowledge of nothing', and if the concept of a central theme around which all parts of a syllabus would revolve be found to be illusory, it is high time we stopped talking about the broad cultural value of science and concentrated our efforts on widening the interests of specialists during or after their technical training. Much can be done by relatively formal teaching, but—if I may judge from personal experience—more depends on the extent to which students are given the time and opportunity to educate themselves by contact with men and women with entirely different interests and outlook from themselves. This is the great strength of the older residential universities; but here again, they may have something to learn from North Staffordshire.

But the older we get the less inclined we are to go back to school. If we want every member of the population to keep in touch with what is going on in the scientific world and to realize its impact on their lives, we must rely on the Press and on the broadcasting authorities. Neither of these is primarily an educational medium; in both cases the main objective is to put science across in a form that readers and listeners find interesting. In respect to music, the B.B.C. has been outstandingly successful; other fields of broadcasting may be less amenable, and it is not altogether easy to know how far an increase in factual knowledge concerning a number of isolated fields of science enables listeners to appreciate the broad social and international implications of science as a whole.

But when all is said and done, science can only play its full part in furthering the welfare of mankind if it is used at a very early stage of education, as a means of encouraging a dispassionate but optimistic attitude towards all aspects of human affairs. To move from national traditions and aspirations to others based on international welfare may prove less painful if we are prepared to look on man and all his problems as a phase in the evolution of the universe and if we have the courage to believe and to teach that he can, by means of his intellect, control and direct his own evolution and destiny.

SUMMARIES OF ADDRESSES OF PRESIDENTS OF SECTIONS

THE VISUALIZATION OF MAGNETIC PROCESSES

IN delivering the presidential address to Section *A* (Mathematics and Physics), Prof. L. F. Bates prefaces his remarks with a brief outline of the ferromagnetic domain concept. He then describes the several ways in which the boundaries and surfaces of such domains in single crystal and in polycrystalline materials may be manifested. He shows how the original Bitter figure technique has given results of great value concerning main domain and closure domain configurations; it has provided considerable support for the ideas of Néel and others as applied to the magnetization processes which occur when single crystal specimens of appropriate shape are exposed to magnetizing fields, and has given visual proof of the important effects of inclusions, defects and strains on magnetization phenomena.

The technique has recently been much extended first by Craik's development of a detachable colloid film carrying with it a record of domain configuration, which can be examined optically and also in a commercial form of electron microscope. Craik and Griffiths have shown that the film technique can be successfully used to examine fine domain structures on ferrite surfaces prepared by the simple cleavage of single crystal specimens. By using films of ever-decreasing colloid concentration, Craik found the minimum thickness of a continuous deposit above a 180°-domain wall on a cobalt crystal to be 10^{-5} cm.

The colloid film techniques restrict the experiments to static observation and to limited ranges of temperature, and recently attempts have been made to develop dynamic methods. Perhaps the most successful is the polarized-light technique of Lee, Callaby and Lynch, which has been applied to the motion of a domain wall in a thin sheet of polycrystalline 'Perminvar', an alloy of approximate constitution $Ni_{45}Fe_{30}Co_{25}$, which has been magnetically annealed by cooling it in a magnetic field. Davis has followed the motion of such a wall by pick-up in a search coil wound on the specimen. Lee, Callaby and Lynch have used the transverse Kerr effect. The specimen is illuminated by a beam of plane polarized light, which forms a small strip on the specimen surface, roughly parallel to the wall, and which acts as a light probe. The reflected light is collected by a microscope, passes through a 'Polaroid' and is thrown upon the cathode of a photomultiplier. As a domain wall moves across the beam, the intensity of the collected light changes, the change being made periodic by the application of a weak alternating field to the specimen. The current from the photomultiplier is amplified and a signal displayed on a cathode-ray oscillograph. By using two light probes a domain wall can be made to move through each in turn, so that the velocity of wall movement can be followed. It is found that the velocity is fixed almost entirely by the eddy currents in the specimen.

An electron microscope has been directly applied by M. Blackman and others to examine the stray fields at the edges of ferromagnetic specimens, and in this way it has been shown that the domains in hematite are unexpectedly large. Spivak and his collaborators in Moscow have obtained direct photographs using the secondary electrons released by a primary beam on the specimen surface. They have also used an electron mirror method. Kaćzer, in Prague, has used a thin 'Permalloy' probe vibrating above the surface of a specimen to map domains. However, all these methods have to date been less informative than the colloid method, and may more readily manifest surface imperfections and inhomogeneities than domain walls, but they may, of course, be greatly improved in future.

MEDICAL ASPECTS OF COMPLEX CARBOHYDRATES

PROF M STACEY points out in his presidential address to Section *B* (Chemistry) that carbohydrates play an essential part in the vital processes of all living cells Their simplest forms, the monosaccharides, are synthesized from carbon dioxide and water in the leaves of living plants by the agency of sunlight and chlorophyll The chemistry of these photosynthetic processes, including sugar interconversions, phosphate transfer and the enzymes involved therein, is now being worked out Likewise, the mechanisms of the build-up and breakdown of the complex carbohydrates, the polysaccharides, is now well established

Microbial and animal cells, devoid of photosynthetic pigments, must use the simple sugars as material and energy sources for their own metabolic cycles The proper carrying out of these cycles is necessary for the healthy condition of every living cell, and in the animal the blood sugar (glucose) balance must always be maintained For the growth and reproduction of cells and tissue, complex polysaccharides must be built up, for example, to form cell membranes, structure and storage material and colloidal fluids, while the pentose sugars form a part of the genes and chromosomes

Some of the important processes in which both simple and complex carbohydrates are involved are discussed by Prof Stacey

(*a*) *General metabolic processes* These involve digestion of foods and the absorption of glucose and other sugars , they involve the metabolic cycles and the function of enzymes concerned with them They concern the synthesis and breakdown of glycogen, the conversion of sugar to fat, the biochemistry of muscle action, formation of milk, etc The hormones insulin and epinephrine are involved in glycolysis The great medical value of insulin in controlling diabetic conditions is well known In this field synthetic substitutes for use in diabetes are being actively studied

(*b*) *Detoxication mechanisms* Frequently the body needs to get rid of excess toxic substances such as drugs, and it can do this by oxidation processes, coupling up with the sugar acid D-glucuronic acid and then excreting the complex D-Glucuronic acid is an important tissue component

(*c*) *Structural components of the body* It is with these substances that we can expect to see great advances in the future, for complex carbohydrates known as mucoproteins and mucopolysaccharides form a large part of components such as bone and cartilage tissue, cell membranes, connective tissue, skin and its ground substance, joint fluids, synovial fluid, eye tissues and fluids, gastric and intestinal mucosa, etc

These complex polysaccharides have as their building units nitrogen-containing or 'amino'-sugars, hexuronic acids and hexoses, and often, too, acetyl and sulphate residues are present Associated with the carbohydrate protein complexes is a novel group of 'nine-carbon' sugars, the nonulosaminic acids, known as sialic and neuraminic acids Detailed work on the chemistry and biological importance of these acids is not yet well advanced Generally, the mucopolysaccharides are concerned with movement of parts of the animal body and thus are important in conditions of arthritis, rheumatism, etc , and with general ageing processes

(*d*) *Blood components* Many components of blood contain complex carbohydrates , the red cell surface contains mucoproteins, white cells contain nucleic acids, while serum contains a wide range of muco-substances

Furthermore, many tissues and fluids of the body such as gastric mucosa, saliva, etc , contain the so-called blood-group factors, which are polysaccharide–amino-acid complexes One of the most important medical developments has been with blood plasma substitutes, where the bacterial polysaccharide dextran has become established as an excellent expander of blood volume The clotting of blood in the body is inhibited by heparin, a complex polysaccharide sulphate, the action of which can be imitated by other polysaccharide sulphates

(*e*) In many other directions carbohydrates are becoming of increasing importance In the antibiotic field, streptomycin is an important complex carbohydrate, while many others such as puromycin, magnamycin and kanamycin contain amino-sugars

In disease-producing agents, the complex surface carbohydrates play a significant part in immunity studies, and there is a close relationship between carbohydrate structure and immunological specificity Pyrogens or fever-producing agents from bacteria are also carbohydrates Muco-substances and the enzymes which destroy them are important in fertilization processes, but little is known at present about the carbohydrates of eggs

A new branch of carbohydrate chemistry is developing in the virus field, and the necrosis of some tumours by bacterial polysaccharides has yet to be studied in detail

RECENT DEVELOPMENTS AND TRENDS IN PALÆONTOLOGY

THE past two or three decades have witnessed a remarkable increase in the output of palæontological research Most of this has been of a purely descriptive character, often related to the needs of the stratigraphical palæontologist, but much has been of more general interest, particularly in the borderline fields of taxonomy and evolutionary theory Prof O M B Bulman attempts in his presidential address to Section *C* (Geology) to give a non-technical account of palæontological activities in some of these directions

Chance plays a large part in the preservation and discovery of fossils, and modes of preservation limit the techniques which can be applied Hence from the nature of his material, the palæontologist has less freedom than the neontologist in planning his research, and is often unable to follow some otherwise desirable line of investigation New material is, however, constantly being obtained, and the scale on which effective techniques are being devised and applied is a distinctive feature of modern palæontology Particularly characteristic of the immediately post-war years also have been the many attempts at constructive syntheses of palæontology and allied sciences

Palæontology provides a general and imperfect, though steadily improving, record of most groups of organisms, and in supplying a few true evolutionary series it has given a fourth dimension to the concept of the species Applying the results of absolute rather than merely relative dating of rocks, it is beginning to contribute some tentative calculations of evolutionary rates in various groups, particularly among vertebrate animals , and the establishment wherever possible of invertebrate phylogenies will have rewarding results here as in other fields The problem of evolutionary mechanism is a purely zoological one, but the ultimate proof or disproof of evolutionary theories involving phylogeny, such as proterogenesis, recapitulation and orthogenesis, also lies fairly within the field of palæontology

The major contributions in palæontology have been made where its limitations have been frankly recognized and its unique assets most fully exploited These are, of course, the time factor and the historical record of evolution To bring palæontological evidence into the evolutionary picture, however, involves a synthesis with genetics, taxonomy and zoology from which is now emerging a new 'science of four-dimensional biology' In such studies, the emphasis has tended to shift from the individual to the population, with the consequent need for statistical treatment, and successful generalizations will call for accurate quantitative as well as qualitative methods of research , but Prof Bulman emphasizes in this address the primary importance of the most detailed and exact morphological investigations which contemporary techniques can provide

MAN AND THE WORLD'S FAUNA

DR L HARRISON MATTHEWS, in his presidential address to Section *D* (Zoology), points out that man has continually preyed on the fauna of the world The increase in the human population and man's technical skills have enabled him to exploit the fauna with ever-increasing destructiveness It was not until the populations of animals were reduced below the danger point that man realized that they were not inexhaustible Destruction of particular species has also been due to man's destruction of the environments to which the fauna has been adapted Human settlement of land and the development of agriculture have caused many animals to be banished from their natural environments

Man now realizes that breeding fauna in captivity will not alone maintain its existence He has introduced legislation prohibiting or limiting the killing of certain species and has provided sanctuaries in the form of reserves It is essential, however, that the conservation be not only applied to the fauna but also to the environments Basically, it is a problem of land management and development, vital to man as a means of producing energy—food and other useful products

For the conservation of animals specifically for commercial purposes, Dr Harrison Matthews gives examples of the recoveries for the fur-seal and the elephant-seal, and how extinction in the Antarctic was prevented by the intervention of the Falkland Islands Government He also mentions the not so satisfactory history of the whaling industry , the only thing that regulations gained here was to reduce the rate of extermination In general, the sea-fishing industries of the world present many complications so far as conservation is concerned, especially the question of replacement of the life-giving plankton On land, over-grazing is often a serious threat to animals , however, some scientists hold the theory that in some cases artificial control is unnecessary, stating that it is effected by natural causes in the long run

Dr Harrison Matthews refers to the population dynamics of certain classes of mammals, and gives an account of the catastrophic 'crash' that invariably arrives after a peak in numbers has been reached, especially in vole-plagues. The over-crowding of the immediate environment that occurs tends to result in psychological tension which eventually causes dysfunction of the adrenal gland , the breakdown of adrenal function causes the rapid death of the animals

A recent inquiry shows that in 1958 the world population increased by 47 millions , at this rate, in forty years time the human population would double It is unlikely, however, that this will occur as the growth of the human population tends to become slower and reach a stable level with the increasing standards of living If we compare the present build-up of population with the cyclic build-up of the population of small mammals, it would seem that we are rapidly approaching the peak and the catastrophic 'crash' Other factors are also likely to control the growth of population, such as atomic war and its radioactive contamination of the atmosphere, social control by inhibiting fertility in either sex, or the emergence of new epidemic diseases

Dr Harrison Matthews points out that the conservation of the world's fauna must be planned on a world-wide scale It must be decided what parts are to be developed for human occupation and what parts are suitable for conserving fauna , already a number of national and international bodies interested in conservation exist , however, as such there has been only little action He sums up by advising all zoologists to study any aspects of biology of the larger animals before it is too late

TRENDS IN URBAN EXPANSION

LARGE-SCALE urban growth, which was a feature of nineteenth-century industrial development in western Europe and eastern North America, is the theme of the presidential address to Section *E* (Geography) by Prof K C Edwards It has continued to the present day, affecting almost all parts of the inhabited world Recent decades, however, have witnessed a sharp acceleration of the process and urban expansion is now going on at an unprecedented rate While industrialization remains a primary factor, it has come to play a relatively less important part in the crowding of people into cities

Owing to the lack of a common definition among different countries as to what constitutes an urban population, precise measurement of the rate of urban growth for the world as a whole is impracticable Some idea of its magnitude over the past half-century so far as large towns are concerned, that is, those of 100,000 inhabitants or more, can be obtained from the figures in Table 1

Table 1

	No of towns of 100,000 inhab or more	Size groups (population in thousands)				
		100-250	250–500	500–750	750-1,000	More than 1 million
1910–13	322	200	63	33	8	18
1950–53	1,071	611	299	67	32	62

Not only has the number of large towns more than trebled, but also a marked upward trend in their mean size has occurred The most spectacular evidence of urban growth is afforded by the millionaire cities There are now about ninety of these vast agglomerations, of which London and Paris were the only examples a century ago, and their number increases yearly Some 200 million people now live in these huge cities, and the day is not far off when they will shelter one-tenth of all mankind

Yet the mammoth cities and existing conurbations do not represent the ultimate stage in the process of urban accretion, for in certain instances groups of these tend to coalesce, forming vast continuous urban areas to which the term 'megalopolis' has been given The outstanding example is the virtually continuous urban belt stretching for 400 miles from Boston to Washington, D C containing more than 30 million people

Whether in the older regions of settlement or in those of newer development, the expansion of cities is mainly due to the movement of people from rural areas and from the smaller to the larger towns The townward drift is primarily the expression of a desire for improved conditions of life In the process no new equilibrium between rural and urban populations is discernible, for food production, despite a dwindling labour force (except in south-east Asia), is increasingly dependent upon technical advances in agriculture To-day the essential relationship is that between urban demands and agricultural productivity

The latest phase of urban expansion has had significant effects upon the individual city The rising importance of service functions of all kinds has substantially altered the structure of urban employment, the growth of administrative and other non-productive activities has intensified the use of the central business quarter, the demand for office accommodation in particular has increased the pressure on building sites, leading to an acceptance of the tall building for such purposes, often in defiance of tradition, retail services have become hampered through traffic congestion and competition for space, resulting in an increased emphasis upon secondary shopping centres in residential districts In connexion with these and other changes, the controlling factor is motor transport Its effects are both centrifugal and centripetal, and the capacity of the city to discharge its functions satisfactorily will increasingly depend upon the solution of problems to which this form of transport gives rise

HOW MUCH SCIENCE ?

THE recent campaign in Great Britain for increasing the proportion of our human and material resources engaged in science, in all its forms, has been supported by a wide range of arguments, some of which are of doubtful validity What tests can be applied to determine if and when there is a shortage of scientists ? It is with this question that Prof J Jewkes commences his presidential address to Section *F* (Economics) To the economist the term 'shortage' has an exact meaning There is a shortage when, at the existing price, the demand is greater than the supply Although the evidence is scrappy, the indications are that there is no shortage of scientists, in this specific sense, in Great Britain at present For the salaries of scientists are not at a level nor moving in a direction which suggests shortage, nor do the latest estimates of probable supply and demand indicate any serious gap between the two

It is frequently suggested that there is, nevertheless, an 'unmet need', implying that those who exercise the demand for scientists are not sufficiently conscious of their value to the community Unmet need is an elusive concept, but four reasons have been given for believing that it exists First, it is said that Britain is lagging behind the United States and the United States behind the U S S R These international comparisons, when they include the U S S R, are for the most part hazardous statistical exercises with non-comparable material Even in the comparisons between Great Britain and the United States many obstacles exist, both as to method and materials It seems to be a reasonable assumption, however, that having regard to their populations, there is no great disparity between the two countries Secondly, efforts have been made to establish correlations between the rate of change of industrial output and of the number of scientists and technologists in industry But the statistical material employed here and the deductions based on it both seem to be unsatisfactory Thirdly, it is sometimes suggested that since some industries spend on research and development relatively more than others, this proves that the second group is lagging Fourthly, attempts have been made to measure the net gains arising out of expenditure on research and development, the results obtained in this way are interesting but do not support any very spectacular conclusions

The scale of scientific activities in the community is determined by a very puzzling combination of public and private views, public and private actions and, in the last resort, the striking of the right balance will inevitably be a matter of informed guesswork and of intuition At the moment the final judgment is probably being distorted by the tendency to exaggerate the part that science has played in raising the standard of living in the past, to overstress the potential material benefits of the more spectacular recent scientific discoveries, and to belittle the contribution made to economic expansion by skills and capacities non-scientific in character

THE CRITICAL IMPORTANCE OF TRANSPORT AND COMMUNICATIONS

IN the modern world, transport affects the citizen and the engineer at every turn In Britain, about 25 per cent of the gross national product is accounted for by transport and communications Not only is the modern State utterly dependent for its daily bread on transport, but also its competitive power depends largely on its efficiency in operation Moreover, it is one of the most easily observed aspects of a country's organization and achievement, and it has a psychological as well as a material impact The subject bristles with technical, economic and political problems, but the aim of Sir Ewart Smith's presidential address to Section *G* (Engineering) is to express some very general thoughts as a challenge to our sense of urgency

In the mid-nineteenth century, Britain had the best transport system in the world, this was largely the creation of engineers, who not only invented, designed and constructed in the technical sense but also often organized the business sides of the ventures they had conceived When, to-day, we compare land transport at home and abroad, we must admit that we have not applied either the technology or the money necessary to keep up with the general advance

Although very recent years have seen some awakening of Britain to its transport needs, a few facts and figures may be mentioned to underline the need for still greater boldness in plans and expenditure

The projected expenditure of £60 million on new roads and major improvements is no more than the 1939 rate, allowing for the fall in the value of money, though the number of vehicles has grown from 3 to more than 7 million, and is increasing at 8 per cent a year While attention is now being paid to motorways, by the end of 1959 only 64 miles will be in use, whereas between 1830 and 1850 new railway routes were being built in Britain at an average rate of 320 miles a year Urban road development lags even more We have no established centre for training high-grade traffic engineers, although the savings to be gained from traffic engineering are immense An increase of only 5 m p h in average speeds—at present 20 m p h in urban districts and 32 m p h in rural—would give an economic saving of at least £180 million a year, and much more as traffic grows

The railways, too, suffer greatly from past neglect of capital expenditure and technical recruitment During 1900–55 true capital outlays were very small, and as late as 1956 only 0 23 per cent of the employees of the British Transport Commission were qualified scientists or engineers In comparison, in the National Coal Board the proportion was 0 7 per cent, in the Central Electricity Authority 2 9 per cent, and in the Atomic Energy Authority 10 9 per cent The British Transport Commission is making valiant efforts to retrieve the position, and the results are likely to be striking Nevertheless, even bolder thinking is desirable, particularly in regard to size of wagons and turn-round (wagons now average only 10 miles/day) It must be stressed that in this the users have major responsibilities as well as corresponding opportunities of gain

In transport abroad, and in our newer and progressive industries, scientific engineers play a much larger part than in the road and rail transport organizations of Britain , we need to train more and use them more widely We must remedy the defects in the transport system of Britain, particularly on the roads, by far greater capital expenditure and by a bolder approach to the technical and organizational problems involved

ARTIFICIAL ORGANS : BIOLOGICAL APPLICATIONS

WE are reminded by Prof A Hemingway, in his presidential address to Section *I* (Physiology and Biochemistry), how much the study of isolated organs and tissues maintained under conditions ensuring survival has yielded to the physiologist These tissues are immersed in, or superfused (a new technique), or perfused with blood, serum or solutions which may be regarded as 'artificial bloods' A solution in which the ionic concentrations of sodium, potassium and calcium were adjusted to maintain conduction and contraction in cardiac muscle was first introduced by Ringer , but since his day many modifications have been made, including the addition of metabolites such as pyruvate and glutamate To make a blood substitute for clinical use as an 'expander' after hæmorrhage or in post-operative hypotensive states, dextrans of appropriate molecular size have been prepared and added to these solutions to make them osmotically equivalent to plasma But, so far, it has not been possible, except by employing suspended red blood corpuscles, to make these solutions adequate carriers of respiratory gases

The introduction of antibiotics and ample supplies of anticoagulants have encouraged and established the use of perfusion and similar techniques for clinical purposes The 'artificial kidney', which has proved successful in the management of certain types of kidney disorder, is a development of Abell's (1922) vividiffusion apparatus The principle is that an artery is cannulated and the blood, rendered incoagulable, is passed through a 20–30 m length of 'Cellophane' tubing which is formed into a spiral and rotated in a bath of modified Ringer's solution According to differences in concentration across the membrane, substances will be interchanged between the blood and the surrounding fluid By this means, substances which have accumulated because of renal dysfunction can be removed from the blood , the rate and the extent of the exchanges can be controlled by regulating the composition of the surrounding bath Ensuing chemical changes in the blood must be followed Treatment by the 'artificial kidney' is indicated when the pathological changes in the kidney are reversible and the patient's kidneys are likely to resume their functions

In the field of cardiac surgery more extensive and complicated operations have been made feasible during the past decade by the development of the 'extracorporeal circulation' This is a method, based on techniques well established in physiological laboratories, by which the systemic circulation of the body can be maintained by a mechanical pump and a blood oxygenator for a period during which the heart and the lungs of the patient can be by-passed. The heart and its neighbouring vessels can then be opened and congenital abnormalities or valvular lesions repaired or modified There are many problems in the design of pumps and oxygenators which, while giving, respectively, adequate flow of blood and sufficient exchange of respiratory gases, will not injure the blood Striking clinical progress has already been made and it seems likely that the improvements in the technique of perfusion will be applied to further studies of organ function and control and, probably, of survival *in vitro*

PERCEPTION, ATTENTION AND CONSCIOUSNESS

IN her presidential address to Section *J* (Psychology), Prof Magdalen D Vernon points out that we can never be aware at any one moment of the whole of our surroundings The degree to which we are aware of them varies greatly, from a precise perception of a narrow central field of view upon which attention is focused, to a vague awareness of all other parts We can vary the amount of attention and the accuracy of perception from moment to moment, and direct it to different parts of our surroundings , but the area of the field, and the number of events or objects in it, of which we can be aware at any one moment are limited Focal awareness of one part of the field may preclude the perception of surrounding parts It appears to be possible, however, to perceive events without being immediately aware of them and to store the information and attend to it later , but such information cannot be retained for long However, there is evidence to show that even when such information never reaches consciousness, it may yet have some effect on thoughts and behaviour

Various factors operate to produce a selection of what is perceived and attended to most closely We tend to perceive primarily what we expect is most probable to occur in the circumstances , and our previous experience of similar situations does much to determine the estimation of probability However, expectation is also affected by the reception of special instructions and information, and by training in what to look for People may also tend to perceive readily what they desire to perceive or are interested in perceiving , but in such circumstances they may imagine they see what is not actually there Again, they may be unusually slow to perceive what would be disagreeable to them But they quickly become aware of sudden and unexpected events which are significant and perhaps potentially dangerous, although they may be slower to perceive fully the exact nature of these events

It is difficult to perceive anything which is exposed only momentarily, or in very dim illumination, or in the margin of the field of vision Nevertheless, there is some evidence to show that material exhibited below the normal threshold of vision, of which the observer is not directly conscious, may in some circumstances affect his thoughts or behaviour, and in particular produce reactions of the autonomic nervous system Attention tends to wander after a time from events of no great interest which recur repeatedly and monotonously, and they may cease to be perceived A long period of exposure to completely homogeneous surroundings produces a decrease in awareness and the power of discrimination, accompanied in some cases by hallucinations and unpleasant emotional reactions

Recent physiological evidence as to the nature and functions of the reticular formation in the sub-cortical regions of the brain suggests that impulses from this formation may stimulate the cortex in such a way as to produce both a general arousal of consciousness , and also the direction of specific awareness to events of particular significance to the individual Cortical impulses in turn may facilitate these activities of the reticular formation, or may inhibit them, for example, in situations associated with the withdrawal of attention, such as those of repeated unvarying stimulation of no interest or importance to the individual Clearly these findings have considerable significance in relation to the psychology of perception and attention, though our understanding of their exact bearing must await further investigation

PLANTS ON LAND AND IN THE OCEANS

FOR his presidential address* to Section *K* (Botany), Dr W R G Atkins prepared an account of the many and varied problems on which he had worked and for which his initial training as a botanist had proved invaluable Starting with a brief account of his work on the suitability and preservation of the timber and fabrics used for the aeroplanes of the First World War, he passed on to an account of his work after the War for the Imperial Department of Agriculture in India It was in India that he started his studies on the *p*H of soils and plant juices, work which he later extended in Britain After his appointment to the staff of the Plymouth Laboratory of the Marine Biological Association, he was able to use *p*H measurements for assessing the total quantity of photosynthesis in water masses in the sea and to initiate complementary chemical hydrographical work at the International Hydrographic Station *E*1—work which has been continued by the staff of the Plymouth Laboratory ever since

Dr Atkins then gave an account of his extensive investigation into the penetration of light into the sea, a factor of great importance for the growth of the phytoplankton These studies were later extended to include measurements of light scattering and of the nature of the light fields to which plants in various environments are subject, both in air and under water In addition to this work, his interest in the plants of the phytoplankton continued Anomalies were often apparent when the crop of phytoplankton was estimated from measurements of the utilization of different nutrients That these anomalies were due to the occurrence on occasion of unsuspectedly large amounts of non-siliceous species was suggested by Dr Atkins—a hypothesis that his later observations and those of other workers have amply confirmed

Curious delays in the time of the spring outburst of the phytoplankton when determined by the sudden reduction in phosphate in the water mass were also sometimes observed These delays did not seem to be due to physical factors, since both the light and temperature were apparently suitable for rapid plant growth A study of the concentration of silicate and of the various species occurring in the water indicated a sudden influx of a fresh water mass into the area—a phenomenon not apparent from records of the temperature, salinity and phosphate, nor from measurements of the total plant population as measured by chlorophyll estimations Thus, after thirty years, at least one good reason for the lateness of the phytoplankton crop had become evident This, however, is not to say that at other times and places changes in the vertical circulation or other factors may not be important It does, however, indicate the value and necessity of the close integration of studies concerned with the concentration changes of all the known nutrients, the physical factors involved and both the total plant population and the occurrence of individual species

PATHOGENIC FACTORS IN THE ROOTING SPACE AND THE DEVELOPMENT OF EVEN-AGED PLANTATIONS

IN his presidential address to Section *K** (Forestry), W R Day says that the distribution of species of tree within the range grown for economic purposes is closely related to productive capacity as determined by available site types adequate freedom from acutely damaging infestations and freedom from infections are, plainly, related necessities Production is based on growth as a natural biological process and its economic value depends partly on rate of growth and partly on quality of production as determined by market value of produce or services rendered Ordinarily, the development of the main stem provides the principal interest in production, and this is governed by the interaction of crown and root as functioning correlatives Given adequate climatic adaptation of species of tree, then, within any suitable limited climatic range, the more important basic environmental variations which determine variations in production-rate are to be found in soil conditions as affecting root growth and functioning

---

* Prepared from notes left by Dr Atkins and read posthumously by Dr C P Spencer, of the Marine Biology Station, University College of North Wales, Bangor

The general tendency in development in forests established as even-aged regenerations is from simplicity towards complexity in canopy structure, the rate of development of this tendency for any given species of tree and assuming relative evenness in climatic conditions is largely a function of the soil conditions which prevail locally The factors which determine the course of development in canopy structure are partly to be found in sylvicultural treatment, but basically in the developing demand by the forest canopy as crowns increase in size, especially during the first decades after regeneration, with reduction in number of stems per unit area and increase in height of tree, and according as this demand can be satisfied by supply of root growing-space as qualified by available water and nutrients Potential demand of a canopy of any given specific composition, according to size of tree and as influenced by stand density, may be considered as a genetic characteristic Since the degree to which this potential demand can be satisfied is determined largely by soil supply conditions it follows that, for any given age and type of even-aged regeneration, variations in canopy development which are natural to the site will occur according to the distribution of variations in the stage of stand development at which volume of canopy demand becomes marginal with site supply and especially with supply from the root growing-space Examples taken from even-aged Sitka and Norway spruce stands are given which illustrate variations in stand structure determined in this way Limitations in edaphic supply necessary for root development and action arise from a complex of physical, chemical and biotic factors the action of which is more or less interrelated Examples based mainly on the physical aspect of clay and sand soils, as observed in the field, are given to illustrate edaphically determined limitation in supply which, through the prevention of growth naturally attempted, acts as a basic cause of disease and in this way influences stand development and, through this, economic production

Examination of the problem of management of even-aged plantations suggests that if the effects of technical sylvicultural treatments are sufficiently to be appreciated, there must be some adequate understanding of the locally occurring inter-relationships between canopy development and site supply of the needs for this, for this, through basically controlling the type of growth possible. will largely determine the effectiveness of the technical treatments practised

WHAT ARE OUR SCHOOLS FOR ?

SIR JAMES J ROBERTSON, president of Section *L* (Education), opens his address by pointing out that it was only within a few weeks of each other that a Scottish judge and the Home Secretary spoke last winter about increased crime and irresponsibility They called for greater help from the schools, only to be rebuked by leading educational journals, which put the blame on bad influences outside Such criticisms focus widespread confusion about the schools' functions and society's ability to protect itself

Our educational philosophy is admirable, but our practice belies our professions, and, while within the task allotted to them our teachers merit respect and commendation, no part of our national education, except our enlightened infant departments, justifies complacency in face of the crisis of our time Admittedly, the ablest pupils in our grammar schools are equal to the demands made on them But do we allow time for their knowledge to be fully assimilated ? To what extent do we quicken sensibility in them, or nourish imagination, or awaken the sense of dependence on others ? Moreover, if we segregate the highly gifted in separate schools at eleven, do we not aggravate the risk of producing 'Lucky Jims' or an arrogant self-appointed élite ?

The average grammar school entrants, supposedly most fortunate, are educationally the worst used of all Despite advantages in staffing and provision, they are the victims of an unsuitable curriculum and an external examination too hard for the majority They suffer from excessive demands on their time, a low level of real attainment, an obsessional concern with examinations, and deplorable neglect of the non-cognitive sides of their natures The vision of the Norwood Committee and the Scottish Advisory Council quickly died amid post-war careerism and greed

Equally deplorable is the largely lost opportunity in the secondary modern schools, with the discrediting of interest and experiment and the ever-increasing participation in the chase after certificates, a participation which can, however, be defended if the General Certificate of Education really matters as much as we pretend, and we put into secondary moderns children capable of securing even scrappy certificates

The bright promise of 1943 for the primary schools also faded swiftly in the universal scramble for status A secondary education like that in Britain presupposes a primary, geared to '11 +', with tests and streaming all the way and those pressures that make short work of frills and experiments Add the excessive size of classes and general inadequacy of provision, and you ensure the dominance of class-teaching and the rigid time-table, with disastrous consequences both to secondary schooling and to any further education adequate to our condition

Further education which is neither vocational training nor purveyed entertainment is at once the most important of all, and in its meagre extent the most disappointing How can it be otherwise so long as statutory schooling creates distaste and does but scant justice to music, drama and the arts ?

Education in Britain accords as ill with recent thinking and discovery as with the sombre realities of our times, taking insufficient account of the rarity of high intelligence, the great range of innate ability and the powerful movements of thought towards an organic and unitary view of man as existent and person Our great need is to awaken to the costliness, both material and spiritual, of all true education reform must begin with a national change of heart

BALANCE IN BRITISH FARMING

DR H G SANDERS suggests in his presidential address to Section *M* (Agriculture) that the forty-seven years life-time of the Section has seen science applied to British agriculture at an ever-increasing rate, and there have also been violent economic changes Farming systems which have been built up in more leisurely times have achieved a balance which might be upset by these scientific and economic impacts There has clearly been an improvement in some aspects of the really basic factor—soil fertility The lime status of the soils of Britain has been raised markedly and is still improving, and the increasing use of chemical fertilizers has led to better plant nutrient content In regard to drainage the situation is less satisfactory There is still uncertainty and much argument over the importance of maintaining the organic matter content of the soil, the danger being that, if it is allowed to fall, soil structure will be lost New chemicals have proved powerful aids in keeping land clean, but there are obvious dangers in their indiscriminate use On many farms the ley has replaced the root crop as the pivot of the rotation, and advanced practitioners are showing how great the production from newly established grass can be Full summer utilization necessitates conserving surplus herbage at peak periods of growth, and silage fits better into advanced grazing control than hay Much is known about the extra cost involved in making high-quality hay and silage, but little about the increased animal production from first-class material and its possibilities in economizing expensive concentrated foods There is urgent need for more applied research into such problems

One aspect of balance in traditional farming systems has been the relation between the feeding-stuffs produced from the land and the head of livestock maintained A high degree of self-sufficiency is still a sensible economic aim, but its attainment depends on high-quality roughages and more precise knowledge of their potentialities, not only as maintenance ration but also for animal production.

A rough balance in the farming of Britain as a whole has grown up in a somewhat haphazard way Sales of store sheep in Scotland are well established, and similar ones for store cattle have recently started and are developing rapidly on the Welsh border The reverse movement of grain and straw from east to west is unorganized and depends on the initiative of individual merchants British farmers have had outstanding success in the development of pedigree livestock, but the future will probably see more use of crossbreds for commercial exploitation In poultry this is already widespread and in sheep also, though with them the benefits are often lost by continuing and indiscriminate crossing The development of a system of pedigree breeders and crossing breeders to provide livestock for the ordinary farmer would help in the simplification of farming which advancing knowledge is making ever more necessary The ultimate solution of this problem of keeping abreast with science should not be monoculture, but mixed farming with the more scientific processes in the hands of specialists

THE ST. LAWRENCE SEAWAY AND POWER PROJECTS : GEOGRAPHICAL BACKGROUND

By Prof T L HILLS
McGill University, Montreal

THE official opening of the St Lawrence Seaway on June 26 brought to completion five years of design and construction of both the Seaway and Power Projects on the St Lawrence River It also brought to fruition more than fifty years of almost incessant agitation in both the United States and Canada for the development of a deep navigable waterway into the heart of the North American continent Yet most significant of all, it will carry one stage further a process that has been under way for nearly four hundred years, since Jacques Cartier was halted in his journey up the St Lawrence by the Lachine Rapids This process has involved on one hand the gradual exploitation of physical features of the Great Lakes–St Lawrence drainage system advantageous to navigation, and on the other, the overcoming of natural obstacles to navigation Successive stages in this process have reflected the economic development of the continent as well as political changes The St Lawrence Valley is the natural outlet of the continent to the North Atlantic and western Europe , therefore, improvement of this waterway was to be expected However, nearly four centuries since European man first arrived on the scene the navigation facilities on the St Lawrence have only just been improved to the point where ocean-going vessels of more than 2,500 tons can be accommodated These navigation facilities are still not comparable with the other great canal systems of the world At present, the Panama, Amsterdam, Rhine, Kiel, Suez, Texas and Manchester Ship Canals all exceed in size the proportions of the St Lawrence Seaway facilities For an explanation of the long delay in the 'coming to age' of the navigation facilities throughout the Great Lakes–St Lawrence system, geographical, historical, economic and political factors must be considered

The St Lawrence River system in combination with the Gulf of St Lawrence and the Great Lakes provides a continuous waterway extending 2,347 miles into the heart of the North American continent from the Atlantic Ocean The length of this waterway, its location and orientation, are three of its outstanding geographical characteristics Mere length alone is not necessarily an economic attribute However, in this case the distance of the penetration into the continent, which is comparable with the great circle route distance between west European ports and the estuary of the St Lawrence, is of the very greatest economic significance because the Great Lakes–St Lawrence system provides an approximate east–west routeway into the heart of one of the richest agricultural and industrial regions on the face of the Earth, a region lying due west of the metropolis of Europe and the British Isles In relation to resource production and potential this routeway is ideally located Its hinterland or contributory region, comprising as it does the Canadian Shield, the greater part of the Interior Lowlands and parts of the central and northern Appalachian System, is extremely rich in agricultural, forestry, mineral and water-power resources It was natural that one of the world's major trade routes should develop between such a region and a heavily industrialized and densely populated Europe

The St Lawrence River provides the only completely natural water gap through the mountain and upland barrier formed by the Appalachians and the south-eastern upturned edge of the Canadian Shield , but for only brief periods in the past four centuries has it been the chief transportation route between the Atlantic and the interior of the continent The St Lawrence has faced competition from Hudson Bay, the Mississippi Valley, the Pacific Coast–Panama Canal route and especially the Lake Erie–Mohawk–Hudson route The economic and political history of the St Lawrence can largely be told in terms of its continued competition with the alternative routeways from the interior of the continent The low-level link between Lake Erie and the port of New York provided by the valleys of the Mohawk and the Hudson gained the ascendancy over the St Lawrence route with the completion of a barge canal between Buffalo and Albany in 1823 The ascendancy resulted partly from a major physical advantage of the more southerly route, and partly from the fact that it was an 'all-American' route between the Middle West and Europe

The major physical advantage of the Lake Erie–New York route is the year-round ice-free condition of the port of New York Inherent in the location of the St Lawrence, a location which in all other respects has proved advantageous, is one of its most serious limitations The winter climate of a region so located in the north-eastern quadrant of a continent within the northern hemisphere is long and extremely cold Below freezing temperatures for at least four months result in the St Lawrence being turned into an iceway rather than a waterway From the year 1887 until the present day the average date on which the ship channel between Quebec and Montreal has been open for navigation has been April 17 , the earliest date throughout that period was March 19 and the latest date May 1 The average date of the last departure from Montreal was December 4, the earliest was November 21 and the latest December 19 Amelioration of conditions during the past decade and more recently assistance from icebreakers have resulted in the lengthening of the navigation season by about two weeks With the completion of the Seaway it has been suggested that the navigation season might well be even further lengthened by an increase in the number and the efficiency of icebreakers, the use of aerial ice surveys and the improvement of aids to navigation

An eight-month navigation season on the St Lawrence and the Great Lakes compared to year-round navigation on the Atlantic coast south of the Gulf of St Lawrence has probably militated against the development of the full potential of the St Lawrence and the Great Lakes more than any other factor, though if deep navigation had been more readily available this limitation would perhaps not have been considered quite so disadvantageous

The other major physical limitation of the Great Lakes–St Lawrence waterway has been, of course, the series of falls, rapids and shallow connecting channels, which unfortunately abound within the system, especially between Montreal and Lake Huron The long delay in successfully circumventing these obstacles has not been due to engineering difficulties but rather to the sheer expense involved In the upper St Lawrence, that is between Montreal and Lake Ontario, all the pre-Seaway canalization was undertaken by Canada, at an expense which was very considerable for a relatively small and youthful country Only in recent years when it became feasible to merge schemes for the provision of navigation facilities and the development of hydroelectric power did the expense appear not too burdensome, for both Canada and the United States It is fortunate that the most serious liabilities of the whole Great Lakes–St Lawrence system are, at one and the same time, very great assets The upper St Lawrence, which has over the years proved the most serious obstacle to the improvement of navigation, to-day provides almost 4,000,000 horse-power of electricity

The natural deep navigation throughout much of the Great Lakes and on the lower St Lawrence and the falls and rapids, seen either as obstacles to navigation or as water-power sites, owe their existence to a varied geological and physiographical history The entire drainage system of the Great Lakes and the St Lawrence covers an area approximately 678,000 square miles in extent, within three of the major geological and physiographical regions of the continent the Interior Lowlands, the Canadian Shield and the Appalachians The Great Lakes and the valley of the St Lawrence lie chiefly within the north-eastern section of the Interior Lowlands Here a great series of Palæozoic sedimentary rocks, primarily limestones, dolomites, shales and sandstones, take a basin-like form, overlapping on to the rocks of the Shield and the Appalachians to the north and the east Differential erosion on these Palæozoic rocks has produced a series of cuestas best typified by the famous Niagara Escarpment, and lowlands, which are to-day partly occupied by four of the Great Lakes and sections of the St Lawrence Valley In general, dolomites and limestones tend to form the higher parts of the region and are the 'fall-makers', while the shales have been removed extensively to form the lowlands and particularly the four lower lake basins Lake Superior lies entirely within the Precambrian rocks of the Canadian Shield The Great Lakes probably owe their origin to a combination of events—structural depression, fluvial erosion, glacial deepening and morainic damming These events gave rise to the great size and depth of the Great Lakes The deepest point in Lake Superior is 1,302 ft , that is, 700 ft below sea-level, while Lake Michigan has a maximum depth of 923 ft , Lake Huron 750 ft , Lake Ontario 774 ft , Lake Erie is relatively shallow, with an average depth of only 58 ft The water surface of the Great Lakes covers an area of 95,000 square miles, an area almost as great as that of the British Isles

The surface of Lake Superior averages 602 ft above sea-level The drop to sea-level is concentrated in two sections of the drainage system between Lakes Erie and Ontario and in the upper St Lawrence between the outlet of Lake Ontario and Montreal There is a total drop of 326 ft from Lake Erie to Lake Ontario, with a vertical drop of 168 ft at Niagara Falls, where the outflow of Lake Erie drains across the resistant Lockport dolomite of the Niagara Escarpment Between the outlet of Lake Ontario and Montreal the St Lawrence drops a total of 246 ft in a distance of 183 miles, and in doing so flows across alternating resistant igneous and weaker sedimentary rocks, which has given rise in turn to a series of alternating rapids and lake basins Immediately on leaving Lake Ontario the St Lawrence flows across a southerly extension of the Canadian Shield, the Frontenac Axis This section is known as the Thousand Islands , it is wide, deep and free of rapids Below it a series of four rapids, collectively known as the International Rapids, because here the Canada–United States border runs along the St Lawrence, provide a drop of 92 ft in a distance of 44 miles These rapids, including the famous Long Sault, have to-day disappeared under the power pool of the St Lawrence Dam Here the engineers won a brilliant victory over the St Lawrence by raising the waters of the river 81 ft behind a dam built below these falls They have developed tremendous water-power and at the same time provided excellent deep navigation which replaces a series of four 14-ft deep canals of the old St Lawrence canal system

Downstream from the International Rapids section Lake St Francis drains via another series of four rapids with a total drop of 82 ft Again this major obstacle has been circumvented by a combined power pool and deep waterway known as the Beauharnois Canal Here again there is a potential 2,000,000 horse-power of electricity, three-quarters of which has already been developed The final major drop of the St Lawrence occurs where Lake St Louis drains over the Lachine Rapids The drop of 50 ft has not yet been harnessed for the development of electric power, and the Lachine Rapids have remained solely as an obstacle to navigation They have additional geographical significance in that the city of Montreal has developed largely as a result of the Lachine Rapids bringing natural deep navigation to an end at this point

The value of the many considerable drops in elevation within the Great Lakes–St Lawrence system as water-power sites is considerably enhanced by two additional physical attributes of the region The Great Lakes in particular, but also the myriads of large and small glacial lakes within the Canadian Shield, act as vast reservoirs with a tremendous storage capacity which results in the outflow not only being considerable but also in being regulated to a remarkable degree The maximum average flow is about 310,000 cu ft per sec and the minimum 144,000 cu ft per sec The variation of about 2 to 1 is in striking contrast to the flow of the Columbia River, with a ratio of 35 to 1, and the Mississippi River, with a ratio of 25 to 1 The average flow in cu ft per sec obviously increases downstream, being 71,000 between Lakes Superior and Huron, 194,000 on the Niagara River, 237,000 in the International Rapids section, and it reaches a maximum volume of 262,000 cu ft per sec where the Ottawa River joins the St Lawrence The relatively uniform annual precipitation within the drainage basin also contributes to the uniform flow and the tremendous volume of water in the system Precipitation varies from 25 to 43 in , with a mean of 33 in

The completion of the combined St Lawrence Seaway and Power Projects brings to a satisfactory stage the development of navigation facilities on the Great Lakes and the St Lawrence and brings closer the complete utilization of the tremendous water-power available Man has long awaited the day when the full economic potential of this vast system would be realized This stage may not yet have been reached, but economic and technological development will probably no longer hinder absorption of any remaining potential into the navigation and power systems of the Great Lakes and the St Lawrence

local *E*- or *F*-region winds in the area of increased ionization produced by these particles, particularly near the conjugate point

Main phase Gas motion due to the explosion which, by the time of maximum of this phase, extends to the region of the meridians through Honolulu and Jarvis Islands G A M King and C H Cummack (personal communication) independently propose a shock front spreading from Johnston Island with radially uniform horizontal speed They associate the arrival of this at each station with the time of maximum of the main phase there, except at Apia, where they associate it with the time of maximum of the final phase

Adopting the idea of a circular horizontal boundary centred on Johnston Island, applied to an expanding conducting cloud, we suggest a broad qualitative interpretation of the magnetic vectors as follows

Fig 3*A* shows the type of distortion produced in the horizontal magnetic field, assuming that the lines of force are to some extent frozen in the gas

Fig 3*B* shows a current system which might be produced by the e m f induced in the northern section of the cloud moving against the Earth's vertical magnetic field, with return current moving preferentially along the meridian and linking up in the region of high ionization near the conjugate point

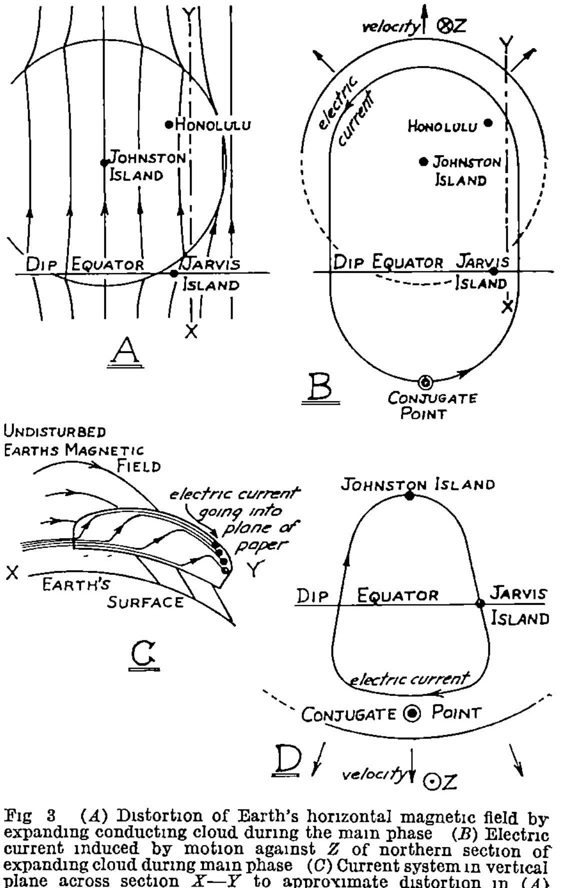

Fig 3 (*A*) Distortion of Earth's horizontal magnetic field by expanding conducting cloud during the main phase (*B*) Electric current induced by motion against *Z* of northern section of expanding cloud during main phase (*C*) Current system in vertical plane across section *X*—*Y* to approximate distortion in (*A*) combined with the current system of (*B*) (*D*) Electric current induced by motion against *Z* of southern section of expanding cloud during final phase

Fig 3*C* shows a vertical section across *X–Y* of Figs 3*A* and *B* In this is pictured a current system which is imagined to combine that of 3*B* with currents to approximate the distortion shown in 3*A*

Note that the return current across the equator contributes to the required distortion, and we suggest that this as well as anisotropic conductivity control the direction of flow.

Final phase A later development of the motion producing the main phase, corresponding to the passage of the shock front over Apia as postulated by King and Cummack In Fig 3*D* we suggest an interpretation of the magnetic vectors on this idea This current system would depend on the abnormal ionization still situated in the whole region between Johnston Island and the conjugate point

The development of all phases after the first explosion is faster, and affects a wider region, consistent with the belief that the first was the highest

We hope to publish a full account of this work in the *N Z Journal of Geology and Geophysics*

Some Geomagnetic Phenomena associated with Nuclear Explosions

The three International Geophysical Year stations operated in the central Pacific by the Scripps Institution of Oceanography have consistently recorded magnetic disturbances following, and apparently caused by, the various nuclear tests conducted by the British in the vicinity of Christmas Island This fact is particularly interesting because, unlike the American bomb which was exploded in the ionosphere over Johnston Island on August 1, 1958, producing auroral and magnetic effects over a large area of the Pacific[1], the British tests are believed to have occurred at relatively low altitudes in the lower atmosphere

Fig 1 shows magnetograms for the explosion of April 28, 1958, and Fig 2 the positions of the observing stations relative to the shot point, which was stated to have been within ten miles of 1° 40′ N, 157° 15′ W The altitude has not been disclosed, but official reports indicate that the device was dropped by a *Valiant* jet bomber, and it may be supposed that the height of detonation was substantially less than the ceiling of about 60,000 ft for that class of aircraft

The pronounced anomalies in *Z* and *D*, which reach a maximum at Jarvis and Fanning between 12 and 15 min after the event and at Palmyra about 10 min later, are similar in character to those which followed other tests, and we have no doubt that they are directly related to the nuclear explosion We have examined magnetograms from the nearest magnetic observatories outside the immediate area, that is, Apia, Guam and Honolulu, but have not found any magnetic effects that we can positively identify with this or with any other of the British tests This is surprising, because Apia and Honolulu are only about three times as far as Palmyra from Christmas Island

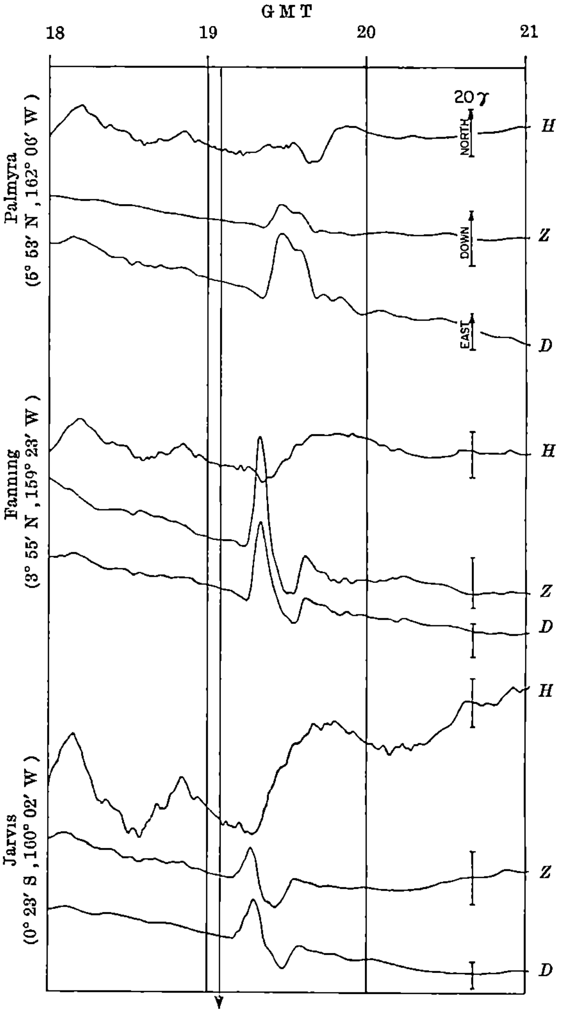

Fig 1 Magnetograms for the Christmas Island nuclear explosion of April 28, 1958

The disturbances recorded at our three stations have several features in common They begin quite suddenly after a delay of several minutes (rather longer at Palmyra than at the other two stations), they move in the same relative phase and they persist for about half an hour, but perhaps the most striking feature of the magnetograms is the absence of any observable disturbance in *H* corresponding to the major disturbance in *Z* and *D* (though an unusual, and probably related, type of local disturbance in *H* at Palmyra commenced about 26 min after the event and lasted for about 20 min) The absence of an *H* component would be explained if the phenomenon involved horizontal currents parallel to the magnetic meridian, and in this connexion it may be noted that the Earth's magnetic field is very nearly horizontal throughout the area More generally, possible mechanisms for producing such disturbances include (*a*) the motion of charged particles, in certain circumstances controlled by the Earth's magnetic field, (*b*)

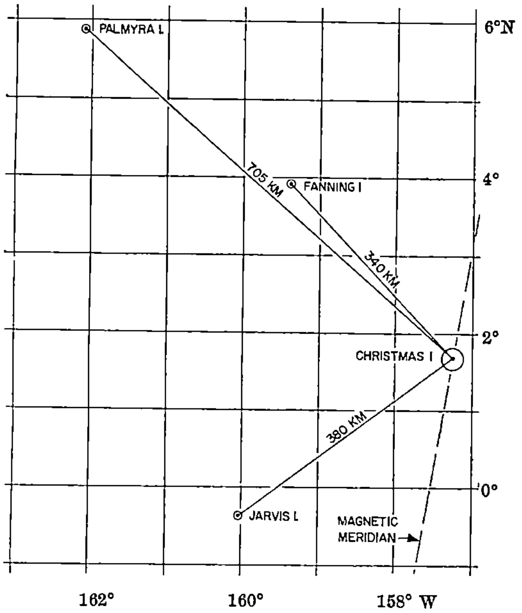

Fig 2 Positions of the Scripps International Geophysical Year stations relative to the shot point near Christmas Island

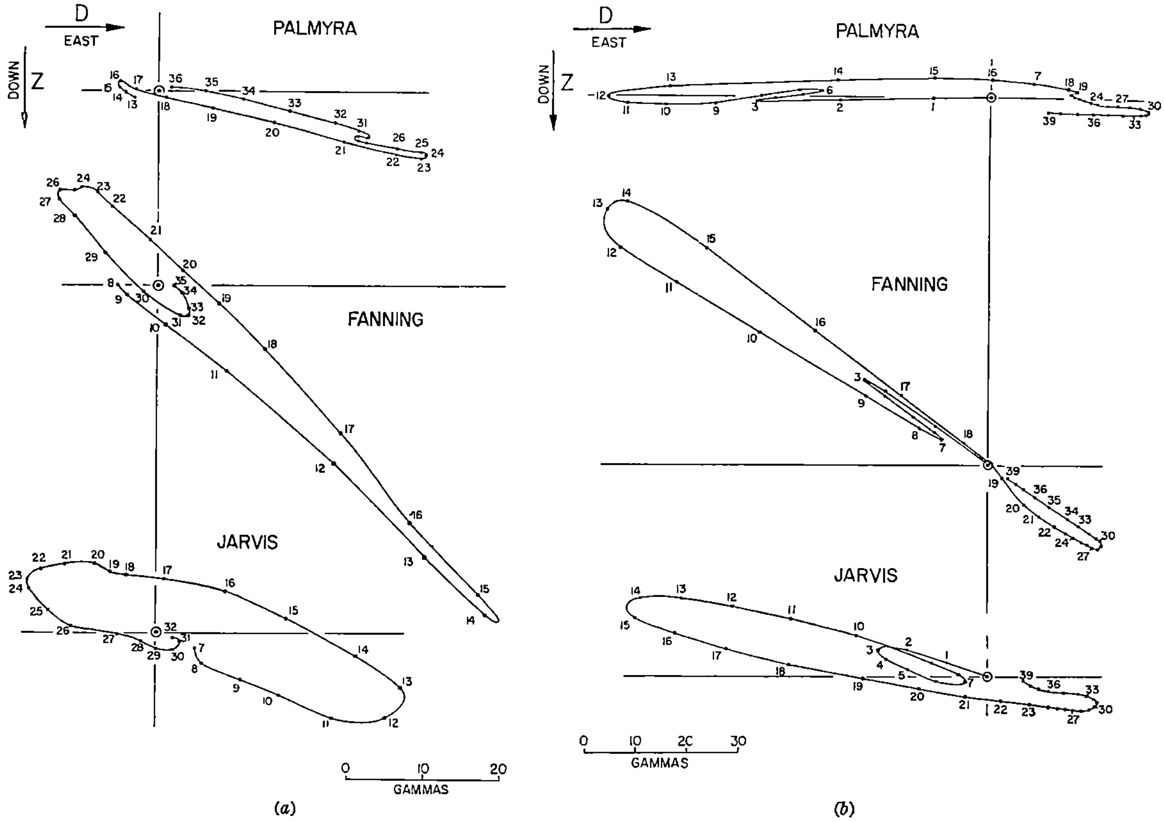
the modification of existing ionospheric currents through displacement of the conducting medium or changes in conductivity, (c) the mechanical disturbance of a magnetic field frozen into a mechanically disturbed conducting medium To these must be added the secondary effect of induction within the Earth

In order to bring out more clearly the vector characteristics of the disturbances, diagrams have been constructed showing the time variation of their projections in various planes, measured as the departure of the observed field from an assumed smooth background (represented by the origin of the vector diagram). Fig 3*a* shows diagrams for the vertical plane perpendicular to the magnetic meridian The explanation of the large time delay at Palmyra is now seen to be that, although the vectors at all three stations reach peak values in one direction between 12 and 16 min and in the opposite direction between 23 and 27 min, the directions and amplitudes of the two peaks at Palmyra are reversed

Fig 3*b* shows the corresponding diagrams for the Johnston Island explosion of August 1, 1958 Having regard to the altogether different geographical positions and altitudes of the two events, the similarity of the two sets of diagrams is remarkable However, unlike the Christmas Island explosion, the Johnston Island event produced changes in H comparable in magnitude with those in D and Z Fig 4 shows vector diagrams of the disturbance in the horizontal plane, plotted to show the relative directions of the magnetic vector, Johnston Island and the conjugate point (taking Elliot and Quenby's position[2]) at each station This event produced effects not observed in connexion with the Christmas Island tests, for example, an instantaneous change in H of about 10 gammas

It is clear from the complicated nature of the Johnston Island disturbance, and from the extent to which it resembled the disturbance produced by the dissimilar Christmas Island event, that no simple



(*a*) (*b*)

Fig 3 Vector diagrams of the disturbance in the vertical plane perpendicular to the magnetic meridian for (*a*) the Christmas Island explosion of April 28, 1958, (*b*) the Johnston Island explosion of August 1, 1958 The small figures indicate the time in minutes after the event

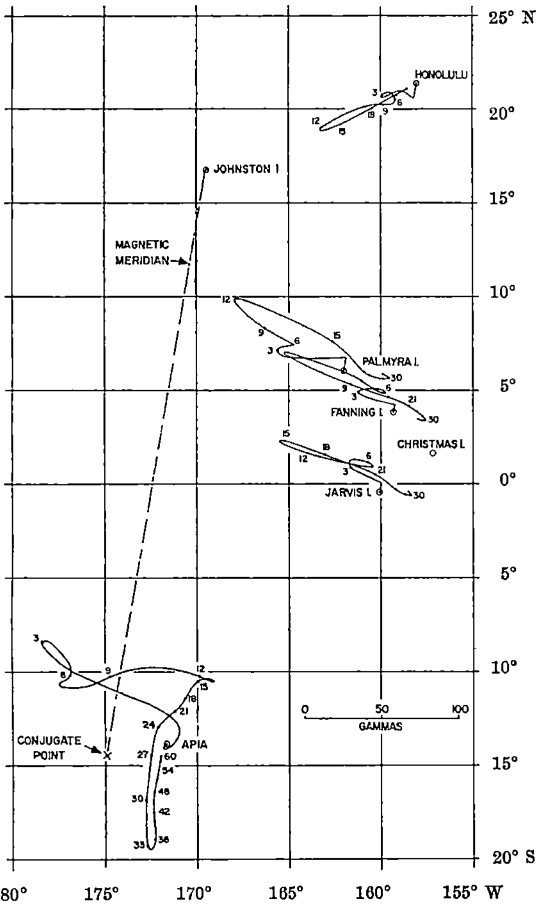


Fig 4 Vector diagrams of the disturbance in the horizontal plane for the Johnston Island explosion of August 1, 1958 The small figures indicate the time in minutes after the event

explanation of the magnetic phenomena is to be expected, it is probable that several distinctly separate mechanisms are involved

CHEMISTRY

Carrier Gas and Sensitivity in Gas Chromatography

A recent article[1] takes issue with the "popular belief that the use of hydrogen or helium as the carrier gas in gas chromatography gives the highest sensitivity with a thermal conductivity detector, because the difference in thermal conductivity between organic vapours and hydrogen or helium is greater than for any other carrier gas" The article goes on to show that, for methane and ethane at least, the sensitivities are considerably higher with carrier gases that have a lower thermal conductivity

The communication by Dr Ray, however, treats the special case where the bridge current of the detector is held constant In practice, not the bridge current, but the filament temperature is held constant Under these conditions, helium is nearly ten times as sensitive as argon

A standard C_4 hydrocarbon mixture was analysed on the same gas chromatographic column under the same condition with both helium and argon as carrier gases, while holding the bridge current constant at 150 m amp Values of the sensitivity parameter[2] (*S*-values) were calculated for the entire mixture; the *S*-value for argon was 252, for helium 300 *Ad hoc* experiments show that the filament temperature will be the same with helium as a carrier gas, operating with a bridge current of 350 m amp, as with nitrogen or carbon dioxide as carrier gas with a bridge current of 150 m amp; argon is in the same range as nitrogen or carbon dioxide The *S*-value for C_4 hydrocarbons in helium, with a bridge current of 350 m amp, is approximately 3,000 In argon, a bridge current of this magnitude would cause the filament to burn out The *S*-values obtained at the same filament temperature closely check the differences that would be expected for argon and helium based on the differences of their thermal conductivities and the thermal conductivities of hydrocarbon vapours helium is 3,480, argon 398, and *n*-butane 322

While it is true that a higher sensitivity can be obtained by using a higher bridge current, it is not usually possible to do this with commercial gas chromatography instruments, because manufacturers wisely limit the supply voltage to a level at which the katharometer filaments do not fuse in air or nitrogen Even with home-made instruments the bridge supply voltage may be a limiting factor, since to maintain the same filament temperature in helium as in argon the voltage must be increased nearly three times

Measurement of Intergranular Diffusion in a Silicate System: Iron in Forsterite

Many geochemists and petrologists[1] concerned with the role of solid state diffusion in material transfer in silicate systems have noted the possibility that grain boundaries and dislocations might act as avenues for relatively rapid movement of the diffusing ions Studies on metal systems are usually cited as evidence for this phenomenon We wish to report some preliminary measurements on a silicate system where grain boundary diffusion seems to predominate in diffusive transfer

The system used for the study was polycrystalline forsterite (magnesium orthosilicate) with ferrous ion as the diffusing material Pellets were prepared from stoichiometric mixtures of the pure oxides by compression at 15,000 lb./sq. in. and sintering at approximately 1,600° C. The samples were broken up and the operations were repeated four times to assure homogeneity. Radioactive iron-55 in a ferric chloride carrier was used as tracer, being applied as a spot in the centre of the forsterite disk. This was baked briefly at 1,000° C. to form ferric oxide, and then reduced at 900° C. in a controlled atmosphere of carbon dioxide and carbon monoxide adjusted to produce fayalite[2] (ferrous orthosilicate). After microscopic examination to detect imperfections and non-adherence, the sample was counted with an end-window Geiger counter under conditions such that the counting geometry could be reproduced exactly. The surface-decrease technique was used. The application of this method to the diffusion of iron-55 in oxides has been described in detail by Himmel, Mehl and Birchenall[3] and by Carter and Richardson[4], and similar methods were applied here. The diffusion annealing was carried out in the range 1,000°–1,200° C. in the controlled atmosphere furnace. Exploratory sections were taken in a few samples after diffusion by careful removal of active layers by grinding in a holder, and residual activity and thickness were measured after the removal of each layer. A few samples were ground at an angle, and autoradiographs were taken with Eastman 'No-screen' X-ray film.

Results for the diffusion coefficient as a function of temperature are plotted in Fig. 1. The straight line calculated according to the least-squares method corresponds to the equation

$$D = 4{\cdot}17 \times 10^{-6} \exp(-38{\cdot}8\ \text{kcal}/RT)\ \text{cm}^2\ \text{sec}^{-1}$$

The statistical limits for 95 per cent confidence for the activation energy are ± 3·6 kcal.

The results for sectioning are given in Fig. 2, for one typical example, and are plotted as log activity against both penetration distance and the square of this distance. According to Fisher[5], theory would predict a straight line in the former case for grain boundary diffusion, and a straight line in the latter case for lattice diffusion. It will be noted that grain-boundary movement is indicated. In all cases, autoradiography confirmed this conclusion. Penetration was found to be non-uniform and concentrated on lines and spots which were rather poorly defined, presumably because of the relative long range of the X-radiation from iron-55.

Despite their importance in geological, ceramic and metallurgical systems, few determinations of diffusion in solid silicate systems have been made. Most notable have been the measurements of Lindner[6]. His work indicates energies of activation for such systems of 47 kcal or greater. The value of 38 kcal found for the present system may be indicative of the greater ease of material transfer through grain boundaries. The picture of such interfaces as regions of ionic misfit with consequent concentration of lattice vacancies and dislocations makes the easier motion of solute ions through such sites readily understandable.

In most solid systems boundary diffusion is considered to play but a minor part in material transfer in comparison with lattice diffusion at temperatures above the Tammann temperature (approximately 0·5 T_m, where T_m is the melting point in degrees K.) because of the small area of the boundaries compared with the aggregate crystal area. The temperatures of the measurements of this study are in this range. However, in orthosilicates we have a close-packed array of ions which may be considered to offer a singularly unfavourable condition for lattice diffusion and prove an exception to the above rule. In such a system, boundary diffusion might be expected to be greater than lattice diffusion, and measurements do seem to give a relatively unambiguous indication that such boundary diffusion can play a part in transfer in a silicate system.

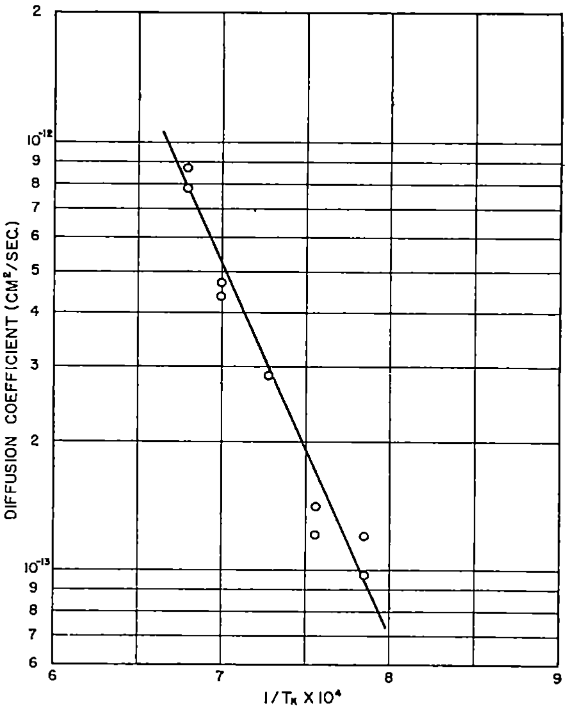

Fig. 1. Diffusion coefficient as a function of temperature

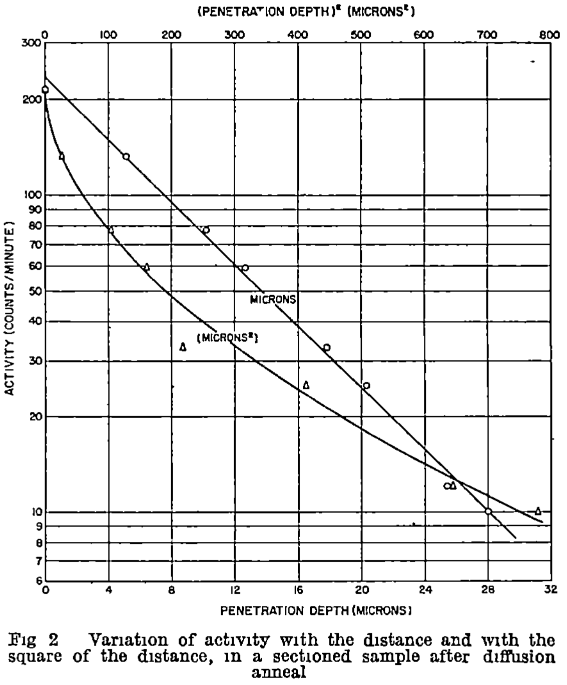

Fig. 2. Variation of activity with the distance and with the square of the distance, in a sectioned sample after diffusion anneal

It is of interest to calculate the distance of appreciable material transfer that would be possible through this intergranular pathway in geological periods of time—say, 10^6 years. By using the mean displacement equation, $X = (Dt)^2$, giving the relationship between the diffusion coefficient D, the time t, and the distance of transfer of the average concentration of diffusing material X, we can obtain an approximation of this last. In the range of 1,000°–1,200° C one finds that a displacement of only 5–17 cm is to be anticipated.

In considerations of petrographic metasomatic processes, particularly those involved in 'the great granite controversy', much argument has centred on the possible mechanisms of transfer of large quantities of matter, sometimes through great distances[7]. One group has sought to account for such transfer by solid state diffusion, and particularly by the intergranular pathway for such diffusion. Within the limitations of the conditions and the system studied, the above results would tend to support those who discount the role of diffusion in long-distance mass transfer, even through the supposedly easy route of the grain boundary.

Influence of Gold in a Mercury Electrode on Certain Electrode Processes

It is usual to study electrode processes using hanging-mercury microelectrodes. Some authors prepare these electrodes by hanging a small mercury drop on a gold wire or a gold-plated platinum wire[1,2], deliberately neglecting the presence of the gold for its electropositive potential. Such an electrode is however an amalgam electrode, and, as we have shown[3], gold can influence the electrode processes of those metals which combine with it to form intermediate compounds.

The actual concentration of gold in different parts of the electrode is variable and dependent upon time, partly due to continuous diffusion of the gold. However, adopting certain approximations, it is possible to evaluate it. For a mercury drop with a radius of 0·05 cm on a gold wire with a surface area of 0·1 mm^2 the concentrations of gold in the mercury 20, 60, 200 sec after the drop was first suspended on the wire are, respectively, 0·001, 0·05 and 0·01 per cent. To ascertain whether those concentrations are sufficient to form intermetallic compounds on the surface of the electrode we have prepared 0·001, 0·01 and 0·1 per cent gold amalgams for use with the

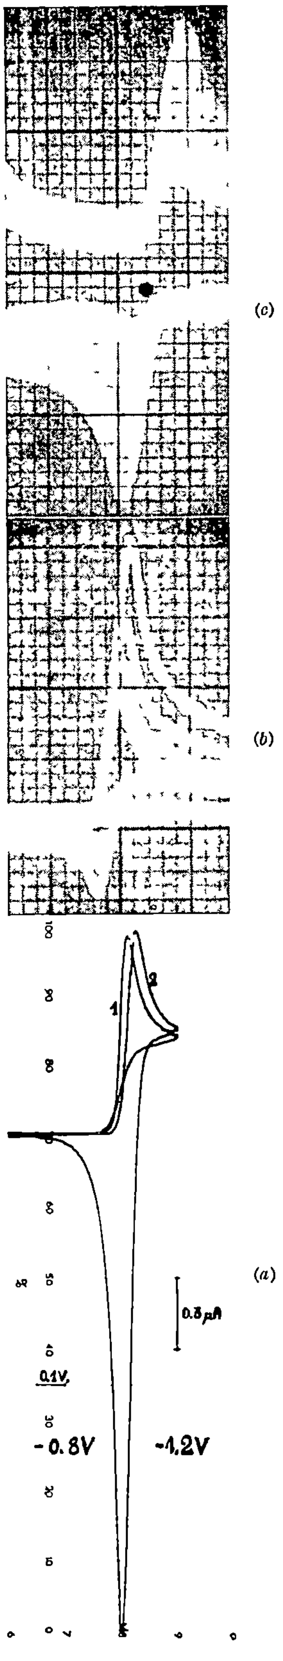

Fig 1

electrodes previously described[4] With these electrodes, $5 \times 10^{-4} N$ solutions of lead, thallium, cadmium and zinc ions were investigated, by means of cyclic polarization of the electrode, using different rates of voltage sweep and recording the corresponding voltammetric and oscillographic curves

It was confirmed that the presence of gold in the electrode greatly influences the electrode processes of zinc Fig 1*a* shows the cyclic voltammetric curves for zinc on the 0 1 per cent gold amalgam electrode (curve 1) and on a mercury electrode (curve 2) They differ significantly in both cathodizing and in anodizing

On gold amalgam the cathodic process is shifted about 20 mV towards more positive potentials compared with a pure mercury electrode The differences in the anodic processes are even more pronounced Zinc is not oxidized at the reversible potential (about -1 0 V), which is caused by the formation in mercury of a compound, AuZn, that can be oxidized at more positive potentials A similar effect can be observed even with less concentrated amalgams Fig 1*c* shows the oscillopolarographic curves for zinc at a frequency of 4 c /s when the exposure was 30 sec and the concentration of gold in the amalgam is 0 01 per cent The more pronounced effect is seen in Fig 1*b*, where the voltage sweep was 0 3 V /sec It is evident that both the reduction current for zinc ions, and the oxidation current of zinc from the amalgam, decrease with time when the compound AuZn is formed This does not occur with the pure mercury electrode The influence of gold can be neglected only when its concentration in the amalgam is less than 0 001 per cent

Similar effects were observed for cadmium, although the intermetallic compound AuCd is not so stable as AuZn Its formation can be observed when the concentration of gold exceeds 0 01 per cent No influence of gold on the electrode processes of lead and thallium was found

Those experiments show clearly that the use of gold or gold-plated wires for suspending the mercury drop can give erratic results if the formation of intermetallic compounds is neglected

On the other hand, our technique for preparing hanging-mercury drop electrodes does not suffer from this difficulty

Carbonate Minerals in Hydrated Portland Cement

ALTHOUGH the physical effects of the carbonation of hydrated cements and mortars have been studied[1-3], the way in which the carbon dioxide is held has not yet been clearly established Most workers have assumed that it exists in the form of calcite , but in work at this Division[3,4] and elsewhere[5] the quantity of calcite detected by X-ray diffraction and differential thermal methods is always much less than the amount of carbon dioxide recoverable from the samples We have investigated this problem in some detail using samples of mortar and carbonated calcium silicate hydrate

From a study of the X-ray diffraction patterns of the materials before and after carbonation, using a Guinier-type focusing camera of high dispersion, we have concluded that the carbon dioxide is chemically bound as calcium carbonate largely in the form of poorly crystallized vaterite, aragonite and calcite These minerals have three-dimensional lattices , this does not support the suggestion of Gaze and Robertson[5], based on indirect evidence, that the carbon dioxide in carbonated tobermorite could be present as two-dimensional calcite Our results also show that well-crystallized calcite is present in small quantities, but that its amount is not greatly increased by carbonation In the past, X-ray analyses have determined the amount of this well-crystallized calcite, rather than the amount of the less easily detected poorly crystalline forms now proved to be present, and so have failed to account for all the carbon dioxide found in carbonated mortars

Other workers[1-3] have shown, and we confirm, that the calcium carbonate minerals have formed both from the decomposition of hydrated cement minerals and from calcium hydroxide produced during the hydration of $3CaO\ SiO_2$ (alite) to xCaO SiO_2 $y$$H_2O$ in the setting of the cement As a result they are intimately associated with a siliceous residue with which they readily react on heating In differential thermal analysis the decomposition of the poorly crystallized calcite produces only a slight endothermic effect (at about 700° C) and its reaction with the siliceous residue to form larnite (β-2CaO SiO_2) is not exothermic Therefore this method, too, gives little or no indication of carbon dioxide minerals other than well-crystallized calcite (strong endothermic effect at about 850° C) in carbonated mortars

Since carbonation of mortars requires the presence of moisture[1-3], we suggest that the process takes place through the action of carbonic acid on cement minerals yielding poorly crystallized vaterite, aragonite and calcite in the following manner Cement minerals → siliceous residue + calcium hydroxide → vaterite + aragonite + poorly crystallized calcite → well-crystallized calcite

A more detailed account of the investigation will be published elsewhere

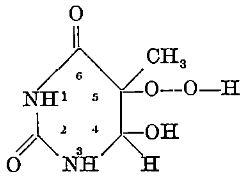
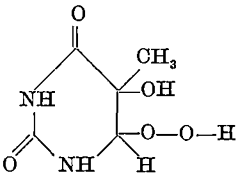
IRRADIATION CHEMISTRY

Structure of Thymine Hydroperoxide produced by X-Irradiation

WEISS *et al.*[1] have shown that X-irradiation of aerated aqueous solutions of nucleic acids, pyrimidine nucleotides or pyrimidine bases gives rise to hydroperoxides. In the case of thymine, they proposed the following possible structures:

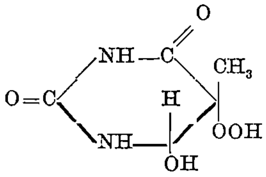


(I)

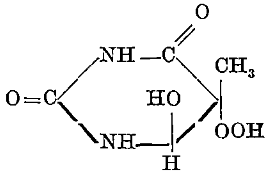


(II)

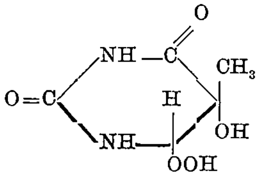
which are in agreement with previous preliminary results from this laboratory[2]. As the hydroperoxide produced by X-irradiation of thymine was sufficiently stable to permit isolation, the synthesis of compounds corresponding to formulæ I and II was attempted in order to compare them with the products isolated from X-irradiated thymine solutions. Each of these two compounds can presumably exist in two forms, *cis* and *trans*:



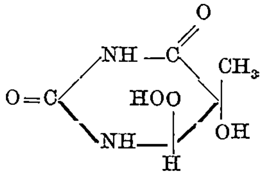
(I *cis*)



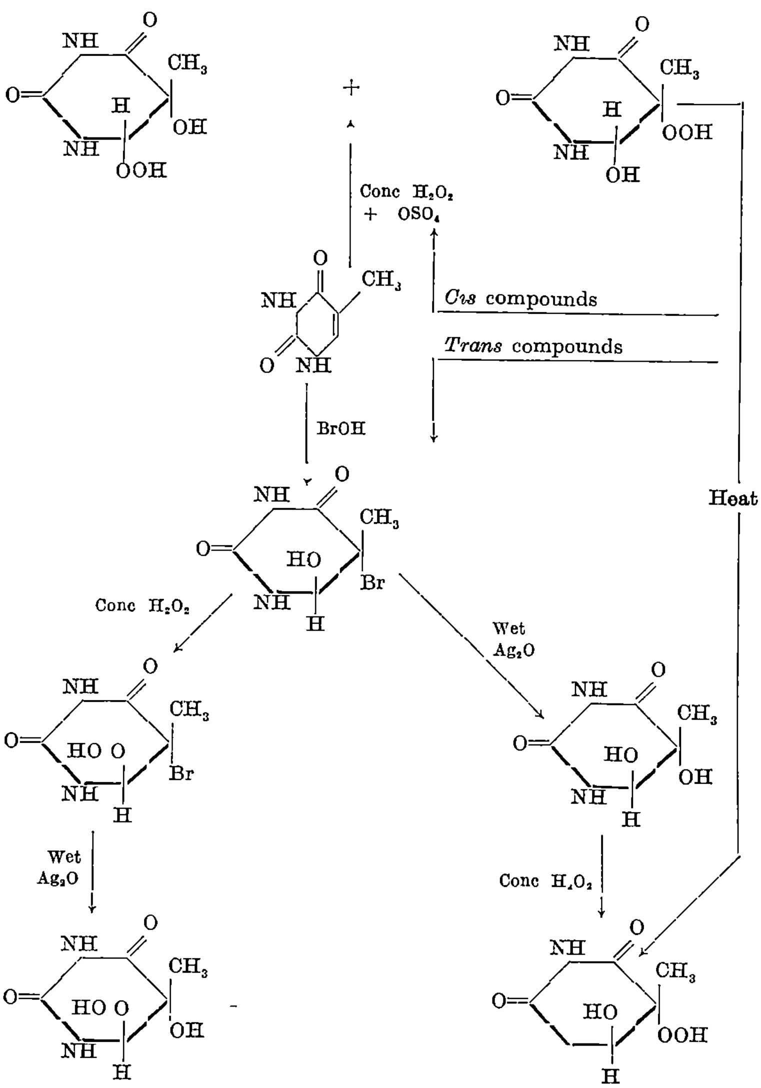
(I *trans*)



(II *cis*)



(II *trans*)



The *trans* compounds were separately synthesized from a common starting material *trans*-4-hydroxy-5-bromothymine, prepared by Jones's method[3]. Compound II *trans* was prepared by treatment of the starting material with hydrogen peroxide in dilute hydrochloric acid to give 4-hydroperoxy-5-bromothymine. Bromine was eliminated by shaking with silver oxide and centrifuging. The product was freed of the last traces of silver oxide by extraction with a chloroformic solution of dithizone. After lyophilization, the residue could be crystallized, with some difficulty, from acetone – petroleum ether. To give compound I *trans*, the starting material was transformed into 4,5-dihydroxythymine[4], which was then treated with hydrogen peroxide. After elimination of excess hydrogen peroxide by repeated lyophilizations, the residue could be crystallized from acetone–benzene. Compounds I *trans*, II *trans* and 4-hydroperoxy-5-bromothymine can easily be separated by paper chromatography, using *n*-propanol/1 *N* hydrochloric acid as a solvent (Table 1).

The treatment of thymine itself with hydrogen peroxide in the presence of catalytic amounts of osmium tetraoxide gives a mixture of two peroxidic compounds, which can be resolved by paper chromatography, giving spots with R_F 0.51 and 0.62 respectively. Since these two compounds do not behave on paper chromatograms like the *trans* hydroperoxides previously described, they probably are the *cis*

Table 1 PAPER CHROMATOGRAPHY OF HYDROPEROXIDIC DERIVATIVES OF THYMINE

Paper, Whatman No 1, solvent, *n*-propanol/1 *N* hydrochloric acid (85/15, v/v), temperature during run, 2° C

Compound		R_F
4-Hydroxy-5-hydroperoxythymine	*cis**	0 51
4-Hydroxy-5-hydroperoxythymine	*trans**	0 33
4-Hydroperoxy-5-hydroxythymine	*cis**	0 62
4-Hydroperoxy-5-hydroxythymine	*trans**	0 43
4-Hydroperoxy-5-bromothymine	*trans**	0 83
4-Hydrogen peroxide*		0 68
Thymine†		0 55

* Detected by spraying a 4 per cent alcoholic solution of potassium iodide

† Detected in ultra-violet light

compounds On heating a solution of the mixture, the product with R_F 0 51 is transformed into a product giving a spot with R_F 0 33, while the product with R_F 0 62 remains unchanged Accordingly, it may be suggested that the product with $R_F = 0$ 51 corresponds to formula II *cis*, as indicated in Table 1 These syntheses and the relationships between the compounds are summarized in the scheme on p 58

All the compounds can be reduced at the dropping mercury electrode in 0 1 *M* potassium sulphate at the same potential near 0 volt, against the saturated calomel electrode at 25° C They behave similarly on 'Dowex 50–H⁺' columns

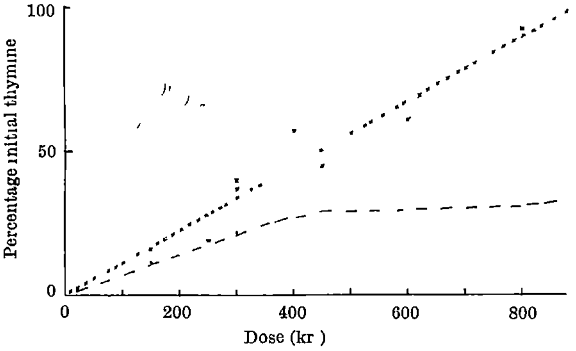


Fig 1 Destruction of thymine (—×—×—) and total production of hydroperoxide (— — —) by X-irradiation of a 10^{-3} M thymine solution by X-rays of 40 kV, filtered through 0 04 mm aluminium, dose, 25 kr, in air

In Fig 1 are shown the curves relating dose to thymine destruction and total hydroperoxide production, during X-irradiation in air A 10^{-3}-M solution of thymine, after irradiation with 400 kr, contained 2 1 × 10^{-5} M hydrogen peroxide and 1 9 × 10^{-4} M hydroperoxide After repeated lyophilizations, the residue was put on a 'Dowex 50-*X* 8' column, 1 cm × 50 cm, in 0 1 *N* hydrochloric acid The eluate was collected in 4-ml fractions Hydroperoxidic products, detected by the iodide reagent, appeared in fractions 5–11, and unchanged thymine in fractions 16–21 After paper chromatography and spraying with iodide reagent, material contained in fractions 5–11 gave a strong spot at the level of the spot given by compound I *cis* and a faint one at the level of the spot given by compound I *trans* Control chromatographs of various mixtures of synthetic peroxides and peroxides produced by X-irradiation demonstrated that the latter cannot be distinguished from the former with corresponding R_F's Therefore, it may be suggested that X-irradiation of thymine in aqueous aerated solutions actually produces hydroperoxides I *trans* and I *cis*

We wish to thank Dr R Laterjet for his interest throughout this work

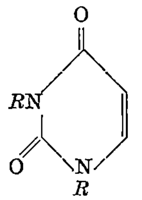
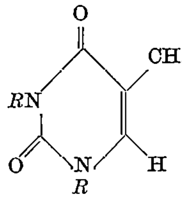
Ultra-violet Irradiation of 1,3-Dimethylthymine

WHEN 5,6-unsubstituted pyrimidines (I) such as uracil, uridine and 1,3-dimethyluracil are irradiated with ultra-violet light, the absorption spectra gradually decrease with a simultaneous increase in end absorption These spectra can be reversed to the original by acid, alkali or heat[1]



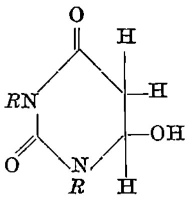
(I)



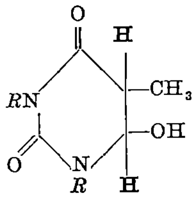
(II)

However, compounds substituted in the 5-position (II), such as thymine, thymidine and 1,3-dimethylthymine, do not show reversal under similar conditions Most investigators have suggested that this difference may be due to totally different photochemical reaction mechanisms in the two cases[2]

Upon close examination of these two groups of compounds it appears that they probably have the same electronic distribution, because the ketonic form as shown above is probably the common and predominant configuration in both[3]. Since the interaction with ultra-violet light is related to the electronic state of a compound, it is not unreasonable to assume that the initial step is similar for both groups of compounds



(IV)

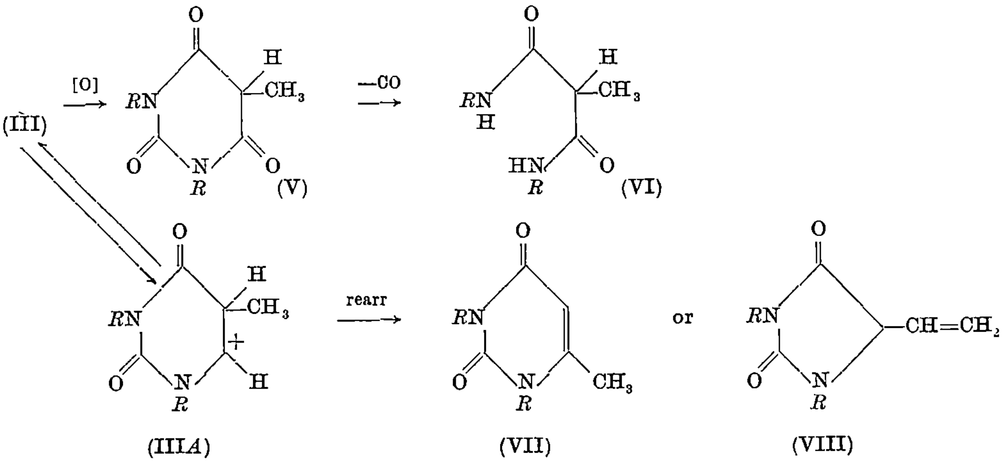


(III)

If the above assumption is true, then 6-hydroxyhydrothymines (III) would be expected as the first products, because 6-hydroxyhydrouracils (IV) have been shown to be the first products of the irradiation of uracils (I) [1] The reconstitution reactions of uracils were found to be dehydrations[1] For thymines, such dehydration would involve the much more reactive III°-H rather than the II°-H as in the uracils Therefore, the dehydration of III is probably much faster than the photo-addition of water to II. This reverse

$$\mathrm{II} \underset{-\mathrm{HOH}}{\overset{h\nu,\,\mathrm{HOH}}{\rightleftharpoons}} \mathrm{III}$$

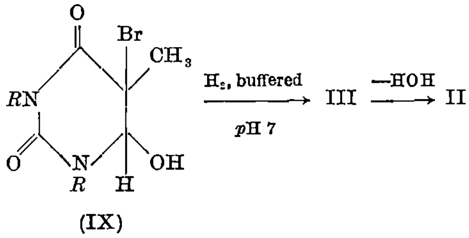
reaction would prevent the detection of III during and after irradiation, and would not be associated with a decrease in the absorption spectrum of II. Actually, however, this spectrum decreased with irradiation, and probably was due to further reactions of III to form irreversible compounds. For such reactions there are two possible routes:



If carbonium ions (III*A*) were formed from III, then through rearrangement either VII or VIII or both could be the products. If 'oxidation' were to occur, according to the route already established for uracils, then V would be the intermediate. Upon decarboxylation N,N′-dimethylmethylmalonamide (VI) would be the product[4].

In order to support experimentally the above arguments, the following two points would have to be demonstrated: first, the intermediate of hydration (III) must be shown to be much more unstable than that of 6-hydroxyhydrouracils (IV); second, one of the irradiation products via the intermediate (III) would have to be isolated.

We have used 1,3-dimethylthymine as a model compound. First, 5-bromo-6-hydroxy-1,3-dimethylhydrothymine (IX) was prepared and was reduced in a manner identical with that used for the preparation of 6-hydroxy-1,3-dimethylhydrouracil[1,5]. Examination of the ultra-violet spectrum of the reaction solution suggested that only 1,3-dimethylthymine was obtained as the product with little indication of the existence of 6-hydroxy derivatives.



(IX)

Upon hydrogenolysis of the 5-bromo-6-hydroxy derivatives of uracils, however, the following yields of 6-hydroxy derivatives were obtained in solution: from uridine, 40 per cent.; from 1,3-dimethyluracil, 80 per cent.; and from uracil, 30 per cent. Therefore, this suggested that III has a much greater tendency for dehydration than uracils have. Second, 1,3-dimethylthymine was irradiated in aqueous solution until a flat ultra-violet spectrum was obtained. The irradiation products were then separated and purified. One of the products has been identified as N,N′-dimethylmethylmalonamide (VI, m.p. 157–158° C. Found: C, 50.08; H, 8.39; N, 19.42. Synthetic VI, m.p. 157–158° C.; mixed m.p. with irradiation product 157–158° C. Found: C, 50.02; H, 8.25; N, 19.65. The infra-red spectra of synthetic VI and the irradiation product were identical.) On the basis of this evidence we would like to suggest that 1,4-addition of water to the thymine derivatives is the first step in the ultra-violet irradiation effect.

By examination of the quantum yields of the irradiation of thymine both in light and heavy water, Shugar has drawn the conclusion that the uptake of a water molecule is not involved[6]. From our findings it would appear that the measurements he made were actually of the subsequent slower steps and probably not for the initial fast reversible step.

Therefore, from the above findings, we have demonstrated that uracil and cytosine derivatives react similarly toward ultra-violet irradiation. This emphasized the fact that for the photochemical pathway of ultra-violet irradiation effects, the differences in electronic distributions of compounds are of more importance than the differences in their structures. They further suggest that the hydration product (III) may be of importance in photoreactivation reactions. Although the first irradiation products of uracils exhibit the phenomenon of reversibility, the irradiated uracils are stable under the customary photoreactivation conditions. Under biological conditions, however, the unstable initial thymine products (III) might be stabilized by secondary linkages, for example, H-bonds, in the nucleic acids. The H-bonds so formed could be broken by the usual photoreactivation conditions. Thus, thymines might be reconstituted and again show the biological activity of the original bases.

This work was carried out under the terms of Contract *AT*(30–1)911 of the Atomic Energy Com-

mission with the Physiology Department, Tufts University School of Medicine. I wish to thank M. Apicella and B. R. Stone for their able assistance.

Degradation of Thiotaurine by Ionizing Radiations

THE degradation of sulphur-containing compounds by ionizing radiation has been extensively studied[1-3] in view of the protective action of those compounds against radiation damage in animals. Recently, thiotaurine (aminoethylthiosulphonate) has become available for chemical and biological investigation[4,5]. Since thiotaurine was discovered as a metabolic product of cystine[6] and cystamine[7] in the rat, and since it is chemically related to cysteamine, it seemed of interest to study its reactivity towards irradiation with X-rays and γ-rays.

30 µmoles of pure thiotaurine dissolved in 3 ml. of water were placed in a glass vessel 2·5 cm. diameter. The solution was irradiated for a suitable length of time with a Philips 50 kV. X-ray source having a beryllium window. The shorter distance from the window to the centre of the solution was 1 cm. The intensity of irradiation was determined with a ferrous sulphate dosimeter[8]. 0·15 ml. of the solution was withdrawn for analysis at intervals.

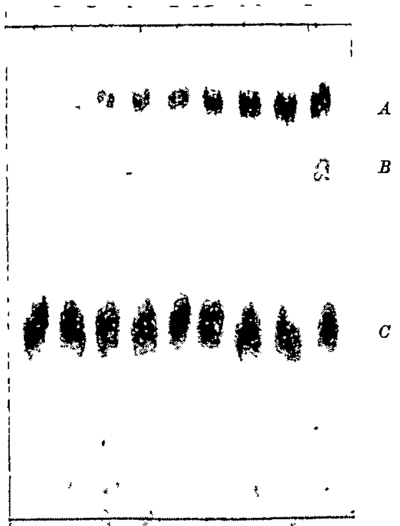

Fig. 1. Progressive chromatogram of the irradiated solution of thiotaurine with X-rays. Dose (r.), left to right, 0, 12,000, 36,000, 60,000, 84,000, 120,000, 240,000, 360,000, 480,000. Descending chromatogram in collidine–lutidine, developed with ninhydrin. 0·5 µmole of initial thiotaurine spotted at the starting line. *A*, hypotaurine; *B*, taurine; *C*, thiotaurine

As soon as irradiation started it became apparent that some reaction was taking place: the solution became more and more turbid. The degree of turbidity increased with the time of irradiation. The unirradiated control remained clear for a long time.

The material which caused turbidity was identified as colloidal sulphur by sedimentation in a 'Spinco' model *L* preparative ultracentrifuge at 125,000*g*, followed by conversion of the washed residue to thiocyanate by the procedure of Bartlett and Skoog[9].

Some of the compounds produced by the radiochemical degradation of thiotaurine have been detected by paper chromatography. At intervals a sample of the irradiated solution was spotted on a Whatman No. 4 filter paper and the chromatogram was run in collidine/lutidine/water (1:1:1 v/v) and developed with ninhydrin. Apart from a residue of unchanged thiotaurine, two main compounds reacting with ninhydrin appeared on the chromatogram. These have been identified, by careful comparison with the synthetic products and by specific reactions[6], as hypotaurine and taurine. Hypotaurine is the first degradation product to appear; its spot appears after a dose of 12,000 r. Taurine appears later and only in small amounts.

The production of hypotaurine and colloidal sulphur is consistent with the following overall reaction:

$$NH_2\text{—}CH_2\text{—}CH_2\text{—}SO_2SH \rightarrow NH_2\text{—}CH_2\text{—}CH_2\text{—}SO_2H + S$$

which represents the reversal of the reaction used for the synthesis of thiotaurine from hypotaurine and sulphur[4].

Essentially the same results have been obtained by irradiating a solution of thiotaurine with a comparable dose of γ-rays from a radium source immersed in the solution. The irradiation of a solution of thiotaurine buffered with phosphate *p*H 7·4 also gave identical results.

It is of interest that cystamine, one of the best known protective agents against radiation damage, under the same conditions and using the same procedure to detect degradation products, gave only a faint trace of taurine even with the higher doses of X-rays. In the light of these results the comparative effect of cystamine and thiotaurine in the radioprotection of animals is being studied.

GEOLOGY

The Geological Time-Scale

Recently Dr. K. I. Mayne, Dr. R. St. J. Lambert and D. York[1] proposed an extended geological time-scale which would place the middle of the Upper Cambrian at about 650 million years ago compared with 450 million years of the Holmes scale[2]. Their scale is based primarily on the ages they obtained by the potassium–argon method on biotite from several British granites; however, they cite many other age measurements for secondary support. It is the purpose of this communication to point out that most of the cases cited are either incorrect or not definitive to the argument. In addition, both they[1,3] and Prof. C. F. Davidson[3] refer at some length to our as yet unpublished isotopic study of the Swedish kolm. These comments contain errors of fact and interpretation which will be clarified by the full report which will appear elsewhere; but in view of the widespread misconception concerning this interesting material some discussion appears needed at this time. The British granites referred to above are being remeasured in this laboratory and results will be reported later.

First, concerning the alleged support of the extended time-scale:

(1) Mayne *et al.*[1] cite pitchblende measurements in the Upper Triassic Chinle formation of the Colorado Plateau by Miller and Kulp as indicating an age of about 210 million years. The published abstract[4] of the oral paper to which they refer does not imply this conclusion, and in the full published paper[5] Miller and Kulp discuss the problems involved and conclude that "The apparent (i.e., isotopic) ages bear no necessary relation to the actual time of deposition".

(2) Mayne *et al.*[1] incorrectly list a result of 360 million years from the Georgia Piedmont as being Permo-Carboniferous in age and refer to a paper by Kulp and Long. In the published abstract[6] the only reference to this area states "In the Southeastern Piedmont of Georgia there is evidence for a younger event occurring around 260 m.y. ago", but there was no attempt to make a stratigraphic assignment. In the oral presentation it was noted that there might be a correlation between this 260 million year metamorphic event and coarse sedimentation in the southernmost part of the Appalachian geosyncline during Carboniferous time; but it was emphasized that no direct stratigraphic correlation with the metamorphic rocks of the Georgia Piedmont is possible. A full report on the age work in the south-eastern Piedmont will appear elsewhere[7] shortly.

(3) The Beryl Mountain pegmatite is actually intruded into the pre-Silurian Ammonoosuc volcanics according to Kruger[8], and not the lower Devonian Littleton formation. Even if the pegmatite were intruded at the time of metamorphism of the Littleton formation as assumed by Damon and Kulp[9], there is no stratigraphic reason for suggesting a Carboniferous age as is done by Mayne *et al.*

(4) The samples of feldspar (Dubuque formation and Mynydd Mawr granite) and sylvite give only minimum ages. The retention of argon in these materials has not been sufficiently well defined to use them for quantitative age determination. Mayne *et al.*[3] in their latest communication agree that little importance should be attached to these dates.

(5) The Boisdale Hills granite, according to the latest geological information (Hurley, personal communication), is not intimately related to the fossil sequence; but presumably the same or a similar granite less than one mile away intrudes a sedimentary sequence dated as Middle Cambrian to Lower Ordovician. The age of 490 million years is therefore much more likely to be a minimum for Lower Ordovician rather than being post-Lower Devonian as Mayne *et al.*[1] state.

(6) The post-Lower Devonian intrusives in both Nova Scotia and Maine as measured by the Massachusetts Institute of Technology group[10] give ages which group at about 365 million years, not 400 million years as used by Mayne *et al.*[1]

(7) The errors on the rubidium–strontium ages on bentonites are too large to allow the ages to be definitive. The Adams *et al.*[11] report was only preliminary, and further work needs to be done before the apparent ages on bentonites can be properly interpreted.

In their reply to Prof. Davidson, Mayne *et al.*[3] correctly reject those points cited by Prof. Davidson as evidence against their extended scale where "either the stratigraphy of the sample or their measured age is not free from unwarranted assumptions". In the above discussion, these same criteria have been used to evaluate the dates and localities used in the first report by Mayne *et al.*[1] as support for their expanded time-scale. The Russian measurements on mica from pebbles in Lower Cambrian rocks, as reported by Davidson[3], cannot be dismissed so easily as Mayne *et al.*[3] have done. If the measurements have been properly made and the minerals have not been altered since, the results are significant. The two pebbles which give isotopic ages of 566 and 763 million years could represent rocks of different real ages. In this case, the younger age would set an upper limit on that part of the Lower Cambrian. It is concluded that the evidence for the extended time-scale lies almost entirely with the measurements made by Mayne *et al.*[1] on the Shap, Cairnsmore and Land's End granites.

The extensive consideration which Mayne *et al.*[1] and Davidson[3] gave the kolm in the Upper Cambrian Swedish black shale is illustrative of the importance of the age of this formation in establishing a time-scale. More than twenty kolm samples from this formation collected over a wide geographical area have been analysed in this laboratory. The isotopic uranium–lead ages are grossly discordant and vary from sample to sample[12]. The detailed interpretation and discussion of these apparent ages are being prepared for publication in another journal[13]. From these measurements it has been concluded that the discordance among the isotopic ages is caused by a combination of bulk lead loss and additional preferential loss of lead-206 due to migration of an intermediate member in the uranium-238 decay chain during the history of the mineral. On this basis, an analysis of the data indicates a minimum age for this formation of about 500 million years. The complexity of the leaching processes occurring is such that a maximum age cannot be assigned solely on the basis of the isotopic data. Mayne *et al.*[1] attribute to us the statement, "They believe the true age to be no greater than 550 m.y." This does not correspond to our opinion, and the reference they cite does not contain this statement. The evidence points to the minimum age as being nearly correct, but there is no unique solution of the data.

Davidson's[3] discussion of the meaning of the kolm ages is erroneous. He mentions that the formation contains old radiogenic lead. Our data strongly indicate that the lead incorporated in the black shale at the time of its deposition was normal in its isotopic composition. His hypothesis that uranium has been continuously introduced into the kolm by percolating ground water is not supported by the observed distribution of uranium in the kolm. Further, it should be pointed out that the effect on the isotopic ages due to introduction of uranium is indistinguishable from that due to loss of lead. Therefore, even if this hypothesis were adopted it would not cause any revision in the interpretation that the minimum age of the kolm is about 500 million years. Davidson's deduction that the formation is necessarily younger than 650 million years since this is the lowest lead-207–lead-206 age is not valid. The meaning of this age is directly dependent on the nature of the chemical alteration that occurred.

The current investigations in a number of laboratories on the age of stratigraphically well-defined rocks will permit a much closer definition of the geological time-scale in the near future. The extended scale proposed by Mayne *et al.*[1] is based on limited data and is not supported by measurements other than their own.

Palæomagnetism and Rotation of Newfoundland

Nairn, Frost and Light have recently reported[1] on the palæomagnetic results from Carboniferous and Pre-Cambrian rocks of Newfoundland. By comparing their Carboniferous results with results obtained by other workers[2] in the western United States they show that Newfoundland may have been rotated 20° anticlockwise since Carboniferous time.

I wish to report some results obtained from Carboniferous rocks of New Brunswick and the Gaspé Peninsula, which, with the results of Nairn *et al.*, show that no relative rotation between Newfoundland and these areas has occurred since Carboniferous times. Therefore, if the proposed rotation of Nairn *et al.* is correct, New Brunswick, the Gaspé Peninsula and Newfoundland must have rotated as a unit.

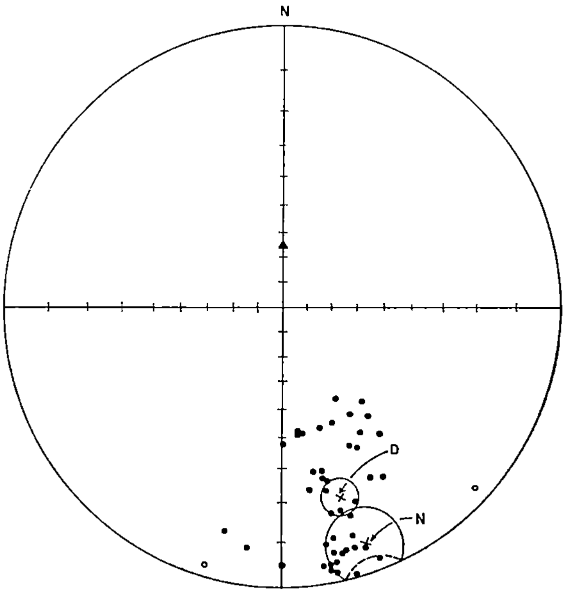

Fig. 1. Directions of magnetization measured in Carboniferous rocks of the Canadian Maritime Provinces. ●, Directions of magnetization of my samples, north pole on lower hemisphere; ○, directions of magnetization of my samples, north pole on upper hemisphere; $X \leftarrow D$, mean direction of my samples (with circle of confidence at Fisher's 95 per cent level of probability); $X \leftarrow N$, mean direction of samples of Nairn *et al.* (with circle of confidence at Fisher's 95 per cent level of probability); ▲, direction of magnetic field produced by a central axial dipole oriented along the Earth's present axis of rotation.

In the summer of 1958 twenty-two samples of the Bonaventure formation (Upper Mississippian or Lower Pennsylvanian) were collected by me from the south shore of the Gaspé Peninsula, Province of Quebec, between Percé and Maguasha. Fourteen samples were also collected from the Kennebecasis formation of Mississippian age at localities about fifteen miles north-east of St. John, New Brunswick. Ten samples were collected by Dr. C. H. Stockwell in the autumn of 1955 from the Pennsylvanian Bathurst formation near Bathurst, New Brunswick. Two 1-in. cubes were cut from each of these samples and were measured on the astatic magnetometer of the Dominion Observatory, Ottawa. The mean direction of each sample has been plotted on a stereogram in Fig. 1. Since rocks were collected from an extensive area, their directions have been corrected to the geographical location 48° N. and 66° W. by assuming that the Earth's average magnetic field is a dipole. The mean direction of the results of Nairn *et al.* from the Codroy gypsum also has been corrected to 48° N. and 66° W. and plotted on Fig. 1.

By inspection one can see that there is no significant difference between the declinations of the Newfoundland samples and of those reported here. This surmise is confirmed by Fisher's statistical analysis which gives a mean direction, corrected to 48° N. and 66° W., of $D = 160·5°$ and $I = +6·0°$ with a circle of confidence of 8·4° for the samples of Nairn *et al.*, and a mean direction of $D = 163·5°$ and $I = +19·5°$ with a circle of confidence of 5·0° for my samples. Thus, there is no significant difference between the two directions, and there is no evidence for any relative rotation between Newfoundland and the mainland Maritime Provinces, since Carboniferous time.

BIOCHEMISTRY

Kinetic Study of Dextransucrase based on the Langmuir Adsorption Isotherm

THE action of the polysaccharide-synthesizing enzyme dextransucrase has been described previously in terms of *p*H [1] and the effect of various alternate receptors[2,3] We have now examined the dependence of rate of reaction on the concentration of enzyme The results are interpreted on the basis of adsorption kinetics[4], where the substrate (sucrose) and acceptor are adsorbed simultaneously on adjacent sites of the enzyme This is followed by glucosyl transfer from sucrose to acceptor No reaction occurs between bound sucrose and acceptor in solution, and there is no separate hydrolytic step prior to the transfer of the glucosyl group

The kinetic studies were carried out by exposing sucrose solutions to varying amounts of crude enzyme solution at 25° C and *p*H 5 2, and measuring the amount of fructose produced at a given time The enzyme was prepared as reported elsewhere[1] Sucrose solution (0 2 ml of a 0 01 *M* solution in 0 05 *M* acetate buffer *p*H 5 2) was incubated with 0 02–1 6 ml of the enzyme solution (assaying 49 units/ml) and buffered to make a final volume of 1 8 ml After ½ hr the reaction was quenched with 0 1 *M* sodium hydroxide and the reducing sugars determined colorimetrically[5,6] A plot of rate against enzyme concentration is shown in Fig 1

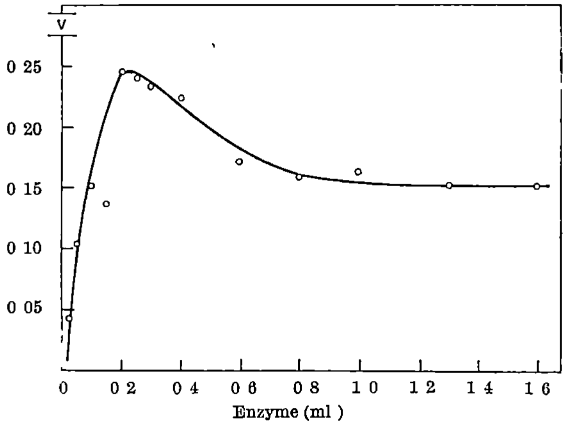

Fig 1 Plot of initial velocity (mgm fructose/1 8 ml /½ hr) against enzyme concentration

The appearance of a maximum in such a plot is rare, however, it has been reported for the lactic dehydrogenase system[7] Laidler and Socquet[4] have treated this case theoretically and have derived the following rate equation :

$$v = \frac{kK_1K_2[E]_0[S_1]_0[S_2]_0}{\{1+[E]_0(K_1+K_1')+K_1[S_1]_0+K_1'[S_2]_0\}\{1+[E]_0(K_2+K_2')+K_2'[S_1]_0+K_2[S_2]_0\}} \quad (1)$$

where k is the rate constant for the decomposition of the complex , S_1 and S_2 are the two substrates, in this case sucrose and acceptor , K_1 and K_2 are the corresponding equilibrium constants for the formation of the binary complex , K_1' and K_2' are the equilibrium constants for the cross adsorption of S_2 on site 1 and S_1 on site 2 respectively It is seen that equation (1) predicts linearity of rate against enzyme or sucrose at low concentration, but an inverse relationship and hence a maximum at high concentration

At high enzyme concentration, the substrates are spread out over a large number of enzyme sites The observed decrease in rate is attributed to the decreased probability that adjacent sites will be occupied in these circumstances The previously observed maximum in the rate against sucrose concentration[8] indicates that sucrose is cross-adsorbed on the acceptor sites (which may well be identical with the donor sites) and thus inhibits the reaction Attempts to observe maxima in S_2 by adding alternate acceptor have been complicated by the presence of the natural acceptor Thus far, only a roughly linear increase of rate with acceptor concentration has been observed

If a reaction were occurring between bound substrate and unbound acceptor, no maximum would occur Furthermore, it has been shown[4] that in cases where one substrate is solvent there is no maximum in the enzyme curve Hence the possibility of a hydrolytic reaction with sucrose followed by a rate-determining combination with dextran is eliminated The presence of the observed maxima thus fits only the case of simultaneous two-substrate adsorption

Agar Electrophoresis of Normal Soluble Proteins in Guinea Pig Liver

HITHERTO, neither free electrophoresis[1] nor electrophoresis on filter paper of the soluble proteins in liver (ref 2, and Smetana, R , and Kořínek, J , personal communication) has afforded satisfactory delimitation of a sufficient number of fractions After obtaining a number of unsatisfactory results on filter paper, we turned our attention to electrophoresis on agar gel

Healthy guinea pigs weighing between 300 and 900 gm were lightly anæsthetized with ether before being perfused with normal saline The liver was ground in a mortar with quartz sand 1–3 ml of a 0 7 per cent solution of sodium chloride (the amount depending on the size of the liver) was added and the whole stored in a refrigerator 24 hr later it was centrifuged at 6,000 r m p for 2–3 hr

Table 1

Fraction	*a*	*b*	*c*	*d*	*e*	*f*	*g*	*h*	*i*	*j*	*k*	*l*	*m*
Average percentage value (*M*)	2 1	6 1	7 1	4 7	4 1	5 5	10 1	19 7	32 5	5 2	1 6	0 6	0 7
Standard deviation (σ)	±0 7	±1 8	±2 1	±1 4	±1 1	±1 6	±2 2	±5 2	±6 7	±1 5	±0 5	±0 3	±0 2

The liquid layer, situated beneath the superficial layer of lipids, was used for the electrophoresis itself

For the agar electrophoresis we used Ilkov and Nikolov's version (personal communication) of Grabar's technique, slightly modified Instead of Grabar's original cuvettes, we used our ordinary containers for paper electrophoresis[3] with platinum electrodes

The dimensions of the glass plate were 23 5 cm × 11 5 cm The agar is poured on a plate, which was held horizontally in 'Plexiglass' frames pressed against the plate itself Double strips of filter paper were previously placed along the two shorter sides of the plate The agar layer was 3 mm thick (45 cm ^{3} for each plate) Three grooves (2 cm × 1 mm) were cut from each plate and their bottoms carefully covered with diluted agar (0 30–0 50 per cent) Dittmer's[4] veronal–sodium acetate buffer (pH 8 6, $\mu = 0$ 06) was used The ionic strength of the buffer in the agar gel was half that in the chamber A sheet of filter paper was placed in contact with the underside of the plate, the ends of the sheet being dipped in water in order to cool the plate During electrophoresis the 'Plexiglass' frame is covered with a glass plate which is turned every 20–30 min A spread of 10–12 cm was recorded after a 5-hr migration at 180–200 V by staining with amido-black 10*B* The electropherograms were scanned with the Zeiss extinction registrator II

Livers of 21 experimental animals were investigated Except in a few cases, two parallel electropherograms were run in each case

Thirteen well-defined fractions were established These were designated with the letters *a* to *m*, beginning with the globulin fractions and ending with the albumin fraction (Figs 1 and 2, Table 1)

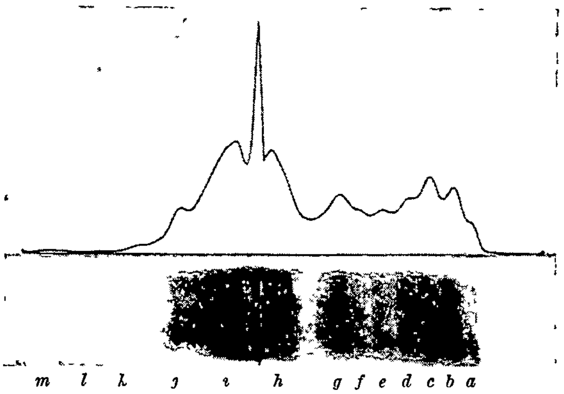

Fig 1

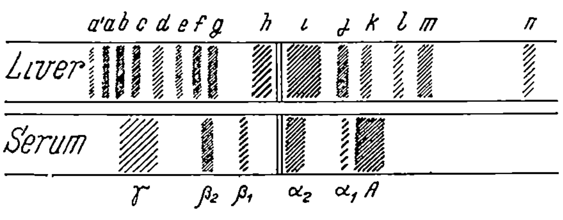

Fig 2

We preferred to label these fractions in the direction opposite to that which is customary because the initial globulin fractions were the best defined Fraction *a* is situated a little behind the γ-globulin, whereas fractions *l* and *m* are in front of the albumins of the blood serum

The interrelations between the remainder of the hepatic fractions observed and the protein fractions of the blood serum can be seen in Fig 2 Fractions *k*, *l* and *m* occur in negligible quantities and are often scarcely established Fraction *i* in Fig 1 is not sharply delimited from fraction *h* In other cases it was clearly delimited, so that its existence is out of doubt A separate fraction migrating beyond fraction *a* (fraction *a'*) was established in certain cases In one instance, we found a fraction migrating faster than fraction *m* (fraction *n*) With these, the total number of fractions observed by us was 15 In view of the fact that fraction *i* is not clearly delimited, however, it is probably composed of a few subfractions It is possible that this may be the case with fraction *h* also Thus the actual number of soluble hepatic protein fractions may be still greater

The average percentage values for the different fractions and the average standard deviations of their respective variation lines are given in Table 1

A few of the electropherograms were tested for lipoproteins by staining with 'Fettrot'–7–*B* Ciba[3] A small amount of lipoprotein could be detected in fraction *i* only

Thus our results show that, in the separation of soluble hepatic proteins, agar electrophoresis has certain advantages as compared to free electrophoresis and to electrophoresis on paper

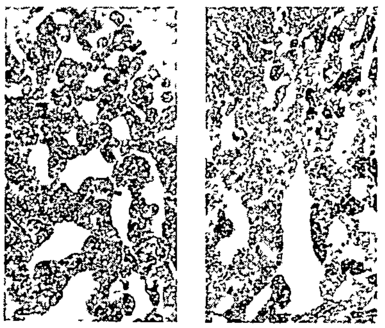
Abolition by Chlorpromazine of the Inhibiting Effect of Iproniazid on the Depletion of Adrenal Catechol Amines induced by Reserpine

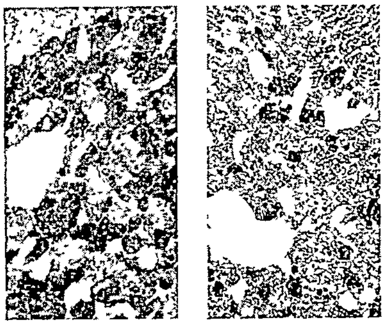
It is well known that reserpine induces a decrease of catechol amines in the adrenal medulla[1–5] In the rat pretreatment with iproniazid, a monoamine oxidase inhibitor, completely overcomes this catechol amine depletion[6–8]

In the present study the modifications of the catechol amine content of the adrenal gland have



(*a*) (*b*)

Fig 1 Adrenal medulla of rat Chromaffin reaction (*a*) A normal degree of chromaffinity is detected in all cells after administration of iproniazid and reserpine (*b*) After administration of chloropromazine in association with iproniazid and reserpine numerous islets of cells completely devoid of chromaffin material are observed (× 44)



(*a*) (*b*)

Fig 2 Adrenal medulla of rat Chromaffin reaction After association of chlorpromazine to the reserpine (*b*), a higher number of chromaffin-negative cells is observed compared to that detected after administration of reserpine alone (*a*) (× 44)

been investigated when chlorpromazine is added together with reserpine and iproniazid

40 male albino rats, Wistar stock, weighing approximately 250 gm were divided into five groups Animals of the first three groups were treated respectively with (1) iproniazid (100 mgm /kgm); (2) chlorpromazine (20 mgm /kgm), (3) chlorpromazine (20 mgm /kgm) and iproniazid (100 mgm / kgm) After 5 hr all the animals were given reserpine in a dose of 1 mgm /kgm The animals of the remaining two groups were treated with chlorpromazine only (20 mgm /kgm) or with reserpine only (1 mgm /kgm) The drugs were injected intraperitoneally Animals were killed by decapitation 24 hr after the last injection The adrenal glands were removed immediately after death and then treated with a potassium dichromate–chromate solution

In the adrenals of rats treated with reserpine the chromaffin reaction shows many groups of cells completely devoid of positive granules irregularly distributed through the normally stained parenchyma (Fig 2*a*) On the other hand, in the rats treated with iproniazid and reserpine, all the cells of the adrenal medulla show a positive chromaffin reaction similar to that observed in the normal gland (Fig 1*a*)

The administration of chlorpromazine and iproniazid before reserpine causes consistent changes as compared with the findings observed after the administration of iproniazid and reserpine alone In these circumstances several groups of cells completely devoid of chromaffin material can be detected (Fig 1*b*), moreover, the number of the non-chromaffin cells is considerably larger than in glands of animals treated with reserpine alone Similar results were obtained for the adrenals of rats treated with reserpine and chlorpromazine (Fig 2*b*) Chlorpromazine alone does not cause any significant changes in the chromaffinity of the medullar cells

These results demonstrate that the inhibiting effect of iproniazid on the adrenaline and noradrenaline depletion induced by reserpine can be abolished by chlorpromazine, moreover, this substance alone does not deplete the catechol amines of the adrenal medulla Since chlorpromazine also increases the depletion of catechol amines following reserpine administration, one could assume that this drug can not only protect the monoamine oxidase from the inhibitory effect of iproniazid but also increases the enzyme activity

We wish to thank Prof G C Dogliotti for his very helpful criticism in this investigation

Destruction of Carotenoids in Isolated Chloroplasts

Booth[1] has recently directed attention to the various mechanisms which are responsible for carotenoid destruction in green tissues, two of which, a photochemical reaction and an enzymic reaction, have been examined in alfalfa leaf macerates[2] Enzymic destruction of β-carotene is reported to be greatest in plant tissues containing chlorophyll[1], and we have therefore made a preliminary examination of the destruction of endogenous carotenoids in isolated chloroplast suspensions prepared from leaves of spinach beet.

Leaves were ground at −1° C in a medium consisting of 0 5 *M* sucrose, 0 067 *M* phosphate buffer (*p*H 7 3), and 0 01 *M* potassium chloride Whole cells and debris were removed by centrifugation at 200*g* for 1 min , chloroplasts were sedimented by centrifugation at 1,000*g* for 10 min , washed once, and re-sedimented before final resuspension in the medium Carotenoids were extracted from the chloroplasts with acetone, separated chromatographically and estimated spectrophotometrically[3] The destruction of carotenoids in the chloroplasts was measured by comparing the amounts present before and after reaction

In order to separate the effect of light from that of heat on the destruction of carotenoids, the experiments on illuminated preparations were carried out at 16° C with illumination from a 100-watt incandescent lamp with a water-cooled condenser For the dark controls, tubes were covered with aluminium foil

When non-aerated chloroplast suspensions were illuminated, 6 per cent of the β-carotene disappeared in 30 min , compared with 4 per cent in the dark Since none disappeared in boiled suspension the reaction was probably enzymic Bubbling air through the chloroplast suspensions increased the light-catalysed destruction of β-carotene to 27 per cent, while in the dark 14 per cent disappeared The relative rates of disappearance of the individual carotenoids were β-carotene > violaxanthin ≫ lutein , the last only started disappearing after 1 hr The order of disappearance of these carotenoids is the same as that of the disappearance of carotenoids in autumn leaves[4]

The addition of Hill reaction oxidants to spinach beet chloroplast suspensions gave varying results 2,6-Dichlorophenol indophenol[5] reduced the destruction of β-carotene in non-aerated chloroplast suspensions to 2 per cent (controls 6 per cent), whereas ferric oxalate–potassium ferricyanide solution[6] increased the destruction to 19 per cent The ferric oxalate–potassium ferricyanide solution had no effect on the destruction of β-carotene in the presence of light and air, but when coupled with the addition of phenazine methosulphate[7] there was measurable inhibition of carotene destruction β-Carotene destruction was stimulated by the addition of *ortho*-phenanthroline[8] to the ferric oxalate–potassium ferricyanide solution in the presence of light and air When zinc acetate[8] was also added, there was a further increase of β-carotene destruction This result was contrary to expectations since zinc acetate reverses the inhibitory effect of *o*-phenanthroline on the Hill reaction[8]

Further experiments on non-illuminated preparations were carried out in which leaf preparations were shaken in a water-bath at 30° C in the dark The activity of chloroplasts from different batches of leaves varied considerably , in some chloroplast preparations 20 per cent of the β-carotene disappeared, whereas in others 50 per cent disappeared, after 1 hr

The enzymic destruction of carotene in chloroplasts in the dark at 30° C was inhibited by phenazine methosulphate *o*-Phenanthroline had no effect, but, in the presence of zinc acetate, *o*-phenanthroline greatly stimulated carotene destruction These effects are somewhat comparable to those found in the light-catalysed destruction and suggest some similarity between the two processes

In an attempt to locate the enzymic system responsible for destruction of β-carotene, a comparison was made of the disappearance of β-carotene in leaf homogenates, chloroplasts prepared from them, and the supernatant fraction which still contained broken chloroplasts In spinach beet leaves there was an almost equal destruction in all three fractions, suggesting that the enzyme system responsible for the destruction was closely linked to the pigment–protein complexes In sugar beet leaves, however, there was more destruction of β-carotene in both the homogenate and the supernatant than in the chloroplast fraction This could be due to the fact that in sugar beet leaves there are at least two differently located enzyme systems responsible for carotene destruction, which would be in accord with more recent findings (Friend, J , and Mayer, A M., unpublished work)

Use of Porter–Silber and Schiff Reagents as Spot Tests for Steroids applied on Paper and their Application to the Study of Rat Adrenal Lipids

THE formation of phenylhydrazones with an absorption maximum at 410 mμ by the method of Porter and Silber characterizes steroids with a dihydroxyacetone side-chain These authors recently reported that the reaction also occurred with the aldehydes of corticosterone and of 11-dehydrocorticosterone and that with the latter compounds the phenylhydrazone developed at a more rapid rate[1] The specificity and difference in speed of the reaction are also evident when it is carried out on paper. A bright yellow colour develops when a region containing a minimum of 2 μgm /cm ^{2} of the chromogen is passed through the Porter–Silber reagent (25 ml water, 41 ml conc sulphuric acid, 34 ml ethyl alcohol and 43 mgm. phenylhydrazine hydrochloride) The colour appears instantly with C-21 aldehydes and their acetates, and in 1–2 hr with steroids containing the dihydroxyacetone side-chain and their acetates It is stable for days provided the paper is not rinsed or warmed, and under these conditions the paper does not char Corticosterone, 17-hydroxyprogesterone and other steroids tested gave no colour at a concentration of 25 μgm /cm ^{2}

C-21 aldehydes, freshly prepared by oxidation with cupric acetate after the method of Beyler and Hoffman[2], may be detected with a Schiff reagent (1 per cent pararosaniline hydrochloride in sulphurous acid), if 10 μgm have been applied over an area of 1 cm ^{2} A purple colour appears as the rest of the paper turns pink The development of the same purple colour in the rest of the paper may be delayed for a few days by encasing the paper in 'Scotch' tape Steroids with an α-ketol- and a dihydroxy-acetone side-chain gave no reaction in amounts of 50 μgm /cm ^{2}, neither did a sample of aldosterone kindly supplied by Merck and Co It is to be noted that freshly prepared aldehydes react at a lower concentration than material which has been stored in the refrigerator or chromatographed in the toluene–propylene glycol system

Both tests have proved helpful in the synthesis and purification by paper chromatography of steroid C-21 aldehydes When a region on paper gave a positive reaction to the two tests and failed to reduce a tetrazolium derivative, the presence of an aldehyde was assumed

The sensitivity and simplicity of the Porter–Silber spot-test should make it a useful tool for the detection of Porter–Silber chromogens in lipid extracts of biological fluids The test has helped in establishing the facts that the incubated rat adrenal secretes little, if any, cortisol or cortisone[3], that the non-reducing, lipid-soluble Porter–Silber chromogen produced by this tissue has the same mobility in the toluene–propylene glycol system as the aldehyde of 11-deoxy-17-hydroxycorticosterone, and that acetylation of the adrenal lipid yields two ultra-violet-absorbing, non-reducing Porter–Silber chromogens, a component with the same mobility in the benzene-formamide system as a product obtained by acetylation of 11-deoxy-17-hydroxycorticosterone aldehyde, and a more polar material[4]

Some Observations on Certain Mucoproteins containing Neuraminic Acid

IT is now well established[1–4] that mucoproteins, particularly those containing neuraminic acids, play a major part in the natural defences of the human body With the object of determining what part is played by such mucoproteins in human cancer we have assessed the amount and distribution of mucoproteins containing neuraminic acid by determination of the neuraminic acid content of tissues obtained in surgical operations for cancer of the stomach, colon and breast, and compared these with those of tissues obtained during removal of ulcers of the stomach and duodenum

Each portion of tissue was extracted exhaustively at room temperature with acetone and later with methanol–chloroform (3 1 v/v) in order to remove any neuraminic acid-containing gangliosides Part (50 mgm) of the fat-extracted residue was suspended in water and dialysed against 0 01 *N* sulphuric acid at 0° for 2 days The neuraminic acid(s) in the non-dialysable residue was then liberated by heating at 80° for 1 hr with 0 04 *N* sulphuric acid and recovered from the neutralized solution by dialysis The neuraminic acid determination[5] was carried out on this dialysate to avoid interference due to chromogens from other sugars

When the whole of the surgical tissue from each operation was examined in this way the neuraminic acid contents of two carcinomas (0 33 and 0 43 cent) from the pylorus end and one (0 64 per cent) from the cardia end of the stomach were appreciably higher than those (0 11, 0 13 and 0 14 per cent) of three stomach ulcers or those (0 12, 0 16 and 0 18 per cent) of three duodenal ulcers In a more meaningful comparison the tissues obtained from later cancer operations were arbitrarily divided into three portions (*A*) the cancerous or centre of the malignant growth, (*B*) the invasive area in which there is an interlocking growth of the normal and cancer cells, (*C*) the apparently 'normal' area outside The results are given in Table 1

Table 1 NEURAMINIC ACID CONTENT IN VARIOUS AREAS OF A MALIGNANT GROWTH

Type of carcinoma	Percentage neuraminic acid content in area *A*	*B*	*C*
Adenocarcinoma of the colon	0 24	0 26	0 17
Carcinoma of the pylorus and duodenum	0 18	0 18	0 11
Scirrhous carcinoma of the breast	0 29	0 11	0 13
Duct carcinoma of the breast	0 16	0 15	0 08

Bearing in mind the difficulty of deciding on the so-called invasive area and the obvious variation in such an arbitrary division, it is nevertheless evident that the amount of mucoprotein containing neuraminic acid is almost doubled in the area of malignancy

Several types of neuraminic acids (N-acetyl-, N,O-diacetyl-, N-glycolyl-, etc) have now been recognized Paper chromatographic and ionophoretic analysis revealed that the neuraminic acid liberated by hydrolysis of the tissue from two stomach ulcers, a duodenal ulcer, a carcinoma of the pylorus, and from all three areas (*A*, *B*, and *C*) of the colon adenocarcinoma and the scirrhous breast carcinoma was N-acetyl neuraminic acid Both N-acetyl and N,O-diacetyl neuraminic acid were liberated from a malignant tumour situated at the cardia end of the stomach and involving 1 in of the œsophagus

In another aspect of this assessment of the distribution of carbohydrate-containing substances in human tumours we have determined[6] the hexosamine contents of some of the tissues studied above Mucoproteins almost always contain hexosamines, but the hexosamine content of the tissue should not necessarily follow the neuraminic acid values since hexosamines are also components of blood group polysaccharides and many tissue polysaccharides The carcinoma obtained from the cardia end of the stomach which had the highest neuraminic acid content (0 64 per cent) also had the highest hexosamine content (3 3 per cent) of those studied The distribution of hexosamine (1 8 per cent in *A*, 1 6 per cent in *B* and 1 2 per cent in *C*) in the colon adenocarcinoma also followed that of the neuraminic acid content However, the hexosamine content (2 1 and 2 0 per cent) of the whole of the surgical tissue from two stomach ulcers and that (2 3 per cent) of a duodenal ulcer differed little from that (2 2 per cent) of the carcinoma of the pylorus Analysis[7] revealed that glucosamine and galactosamine were the only amino-sugars present in the duodenal ulcer (glucosamine galactosamine, 1 9 1) and in the carcinomas from the pylorus end (glucosamine galactosamine, 2 1 1) and from the cardia end (glucosamine galactosamine, 2 3 1) of the stomach Trypsin digestion[8] of the fat-extracted tissues from the same duodenal ulcer and the two stomach carcinomas, removal of protein with trichloracetic acid and addition of alcohol gave crude polysaccharide mixtures in yields of 2 2, 2 1, and 2 3 per cent espectively Acid hydrolysis of these mixtures iberated hexosamines, fucose, and galactose together vith small amounts of glucose and mannose This uggests that most of the polysaccharide in these issues was of the blood-group substance type The lucose probably originated from the glycogen[9] vhich constituted 0 35 per cent of the duodenal lcer tissue and 0 30 and 0 29 per cent respectively f the stomach carcinomas (all yields calculated on he dried fat-extracted tissue) Ionophoretic analysis f the crude polysaccharide mixtures revealed the resence of small amounts of acidic polysaccharides taining with toluidine blue[10] accompanied by much arger amounts of neutral polysaccharides

We are indebted to the staff of the West Bromwich nd District General Hospital, West Bromwich, taffs, for the provision of tissues We have also ad valuable discussion with Prof J W Orr and r D L Woodhouse of the Cancer Research Laboraories One of us (D J T) thanks the University of irmingham for the award of a scholarship The esearch was supported by a grant from the British mpire Cancer Campaign

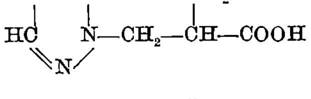
α-Amino-β-(pyrazolyl-N) Propionic Acid: a New Amino-Acid from *Citrullus vulgaris* (Water Melon)

DURING recent years, several new amino- and mino-acids have been characterized as components f the non-protein nitrogen fraction of plant materials nother example has now been found in seeds of *itrullus vulgaris* (water melon, var Tom Watson) he structure of this new amino-acid (hereafter ermed β*PA*) is as follows



α-Amino-β-(pyrazolyl-N) propionic acid
or β-(pyrazolyl-N) alanine

This amino-acid is unique in that it is the first xample of a natural product which contains a yrazole ring Furthermore, in contrast to the other eterocyclic ring-containing amino-acids, histidine and tryptophan, the side-chain of β*PA* is attached to the pyrazole ring through a carbon to nitrogen bond

The presence of the amino-acid was detected by two-dimensional paper chromatography (water-saturated phenol butanol/acetic acid/water) in a 70 per cent (v/v) ethanol extract of ground seeds It occupied a position very similar to that of proline on two-dimensional chromatograms The compound reacted with ninhydrin to give a normal bluish-purple spot With Ehrlich's reagent (*p*-dimethylaminobenzaldehyde) it gave a yellow-coloured spot, and it formed a copper complex with copper acetylacetonate, so indicating the presence of an α-amino group

By ion exchange chromatography ('Zeokarb 215' and 'Dowex 50'–0 25 *N* ammonia displacement), 3 gm of β*PA* was isolated from 10 lb of water melon seeds. The amino-acid was crystallized twice from distilled water (solubility approximately 4 gm / 100 ml), and yielded a white solid with an elemental analysis of C, 46 7 , H, 5 7 , N, 27 1 , O (by difference), 20 4 The calculated values for β*PA* are C, 46 4 , H, 5 8 , N, 27 0 , O, 20 8

Therefore, the isolated material had an empirical formula of $C_6H_9N_3O_2$, and was isomeric with histidine This formula provides too few hydrogen atoms for the more normal saturated open-chain amino-acid structure The compound was found to be stable to strong mineral acid (6 *N* hydrochloric acid at 100° for 24 hr) and alkali (5 *N* barium hydroxide at 100° for 24 hr) Treatment of the isolate with 55 per cent (w/w) hydriodic acid at 120° for 24 hr degraded it, and alanine was identified as the only ninhydrin-reactive product by comparison with an authentic sample of the amino-acid on paper chromatograms developed in water-saturated phenol, butanol/acetic acid/water mixture, butanol saturated with 2 *N* ammonia, and ethyl acetate/pyridine/water (organic phase of 2 1 2 parts by volume mixture) The fission of an alanine moiety in this way not only indicated its presence in the structure of the isolate but also suggested that the alanine residue was attached to the remainder of the molecule through a C—N linkage (the corresponding C—C linkage found in histidine is stable to hydrogen iodide reduction)

The remaining atoms of the formula are most simply accommodated by assuming the presence of an imidazole or pyrazole ring system It would appear that Shinano and Kaya[1] have isolated a smaller quantity of the same substance from the press-juice of water melon , both isolates had the same elemental analysis and m p (decomp) in the range 236–238° C The Japanese workers suggested that their isolate was α-amino-β-(imidazolyl-N) propionic acid, although no definite proof for the presence of the imidazole residue was given Our evidence provides no support for the idea of an imidazole ring The isolate failed to give the Pauli test, and did not possess a *pK* in the *p*H range 6–7, normally a feature of imidazole derivatives Pyrazole derivatives have an analogous *pK* in the *p*H range 2–3 , the titration curve of the isolate showed a weak point of inflexion in this range Nuclear magnetic resonance spectra[2] performed on the isolate and various N-substituted imidazole and pyrazole derivatives proved almost certainly that the isolate contained the pyrazole ring system The fine structure of the spectrum of the isolate also indicated an unsubstituted α-amino group in the alanine residue and the presence of a —CH_2— group and an N—C linkage These requirements are all met by the above structure for β*PA*

Crude, small-scale preparations of β*PA* and β-(imidazolyl-N) alanine (β*IA*) have been made The silver salts of pyrazole and imidazole respectively were refluxed in methanol with the methyl ester of β-chloroalanine hydrochloride (prepared by the method of Fischer and Raske[3]) After removal of the methanol and hydrolysis with 6 *N* hydrochloric acid, the reaction mixtures contained three amino-acids Serine and a trace of a compound, probably alanine, accompanied either β*PA* or β*IA* The synthetic β*PA* was inseparable from the isolated material on paper chromatograms, whereas β*IA* was easily resolved from the isolate β*IA* had an R_F very similar to that of histidine in water-saturated phenol, in butanol/acetic acid/water mixture it moved slightly more slowly than histidine The yields obtained in these preparations were low, but it is hoped that a future large-scale preparation of β*PA* may provide sufficient crystalline material for comparisons to be made with the natural substance using other accepted physico-chemical techniques

We wish to thank the Ferry-Morse Seed Co (California) for supplying the seed, Dr I L Finar for advice on the syntheses, and Drs J H Ridd and R F M White for their help with the nuclear magnetic resonance spectra

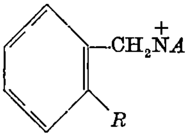
ANIMAL PHYSIOLOGY

New Antiadrenergic Compounds

WE have found that the benzyl quaternary ammonium compounds (I, patents pending) have a novel and highly specific blocking action on the peripheral sympathetic nervous system, which resembles that following section of adrenergic nerves and differs from that produced by adrenolytics, ganglion-blocking agents and reserpine



(I)

Compounds of the above type were screened by examining their efficacy in relaxing the nictitating membrane when injected subcutaneously in the cat Activity was highest in the quaternary compounds (I, *R* = H) and the *ortho*-substituted analogues (I, *R* = *Me*, F, Cl, Br, I, and NO_2) Activity was also very sharply influenced by the cationic head, high activity being encountered in the compounds I with *NA* = NMe_2Et, $NMe_2(CH_2)_2OH$, $EtN(CH_2)_4$, $HO(CH_2)_2N(CH_2)_4$ Lower homologues such as I with *NA* = NMe_3, *R* = Br were inactive and higher homologues showed much reduced activities There was no mydriasis or other overt effect in cats injected with any of these compounds, except one (I, *NA* = NMe_2Et, *R* = H) which caused marked parasympathomimetic effects

One of the most active compounds, 373*C*57 (I *NA* = NMe_2Et, *R* = Br), was examined in detail, as its bromide, and the findings indicating its mode of action are summarized as follows

After subcutaneous injection of 5–10 mgm /kgm of 373*C*57 in the unanæsthetized cat, the nictitating membrane gradually relaxed, becoming fully exposed in 4–6 hr , and retracted only after approximately 24 hr Similarly, in cats under chloralose anæsthesia 373*C*57 gradually inhibited the effect of indirect stimulation of the nictitating membrane irrespective of whether the stimuli were applied to the pre- or post-ganglionic nerve , the block was most marked when the stimulation was continuous This inhibitory effect was accompanied by a gradual and prolonged fall in blood pressure often preceded, when the drug was given intravenously, by a small temporary rise The response of the heart to stimulation of the cardio accelerans nerve was blocked, and the pressor effects of intravenous injections of adrenaline and nor adrenaline were increased

373*C*57 blocked the response to stimulation of the adrenergic nerve in various isolated preparations Thus it prevented the vasoconstriction caused by stimulating the greater auricular nerve in the perfused rabbit ear, the relaxation of the rabbit ileum during stimulation of the visceral efferents, and the contraction of the rabbit uterus elicited through the hypogastric nerve The effects of adrenaline and noradrenaline on these preparations were enhanced after giving 373*C*57

In the cat, the pressor effects of intravenous dimethylphenylpiperazinium iodide and splanchnic nerve stimulation which are mediated by the adrena medulla were greater after giving 373*C*57, whereas the hypertension caused by the ganglion-stimulating action of dimethylphenylpiperazinium iodide in the adrenalectomized animal was blocked This shows that the antiadrenergic action of 373*C*57 is not accompanied by an interference with the adrenal mechanism, such as occurs with the ganglion-blocking drugs or reserpine

Some of the properties of 373*C*57 resemble those of the 2 6-xylylether of choline bromide, *TM*10[1,2] but unlike this compound, 373*C*57 does not cause parasympathomimetic effects or deplete the pressor amine content of the rat adrenal ' The latter finding if it applied also to the adrenergic nerve, would indicate that it is unlikely that 373*C*57 acts either by depleting the local stores of catechol amines or by inhibiting the biogenesis of noradrenaline in adrenergic nerves, as was postulated[3] might be the mode of action of *TM*10 373*C*57 caused no overt behavioural changes in animals, and this together with the absence of depletion of the catechol amine content of the adrenal medulla of rats is in contrast with the actions of reserpine

Together with our colleagues, Drs A McCoubrey and W G Duncombe, we have studied the distribution in tissues of 373*C*57 labelled with carbon-14 in one of its methyl groups Following subcutaneous injection in cats, much higher concentrations of radioactivity were found in adrenergic nerves, sympathetic ganglia and tissues with a rich adrenergic innervation, than in other tissues The concentration of 373*C*57 indicated to be present in adrenergic nerves, when applied topically, blocked the physiological responses to stimulation of the pre- and post-ganglionic cervical sympathetic nerves in the cat, the visceral adrenergic nerves of rabbit intestine, and the greater auricular nerve in the rabbit ear

We conclude that the blocking effect of 373*C*57 on the peripheral sympathetic nervous system is due to an action on adrenergic nerves and that its specificity is related to the selective accumulation of the compound in adrenergic nerves following systemic administration

The properties of 373*C*57 and related antiadrenergic compounds may render them useful for the reduction of sympathetic tone, for example, in the treatment of hypertension, they do not impair parasympathetic functions as do ganglion-blocking agents, nor depress the central nervous system as does reserpine

Note added in proof We have just learned that the open name, approved by the British Pharmacopœa Commission, for 373*C*57 *p*-toluene sulphonate is 'bretylium tosylate'

Action of Ganglion Blocking Drugs on Choline Acetylase

THE first practical hypotensive drugs which acted by causing autonomic ganglionic block were *bis*-quaternary ammonium salts, recently, substances containing only a single secondary or tertiary amine group have been introduced as hypotensive agents of a similar type There are, however, differences in the details of the pharmacological actions of the two types of drugs, for example, the mono-amine compounds, mecamylamine and pempidine, are slower in onset of action but more prolonged when compared with the older group (for example, hexamethonium or pentolinium) The *bis*-quaternary ammonium drugs paralyse ganglia by extracellular competition with acetylcholine for synaptic receptor sites, the differences in action might be explicable if the newer compounds acted in some other way, for example, by inhibition of acetylcholine formation Their ability to penetrate cell lipid membranes or barriers makes such an intracellular action plausible

Choline acetylase preparations from guinea pig brain have therefore been used to compare the effects of three of these mono-amine compounds with those of a 'hemicholinium' (*HC*-3), a compound which is known to owe its high toxicity to interference with acetylcholine synthesis[1-2] The enzyme preparations used were modifications of those previously employed and were more dependent on the addition of choline for their activity *HC*-3 inhibits only the weaker '*P*' preparation, this action results from its competition with choline for some limited path of entry into the less damaged particles of that preparation[2]

The three mono-amine compounds tested (mecamylamine, pempidine, and its ethyl analogue, Imperial Chemical Industries Cpd 26539), showed no significant inhibition of either enzyme preparation when tested in the concentration (10^{-4} *M*) at which *HC*-3 reduces the activity of the '*P*' preparation by one half Pempidine was also ineffective at 10^{-3} *M*, a concentration which would be expected to reveal any ability to interfere specifically with the enzyme system

2 vol 0 9 per cent w/v sodium chloride
1 vol 0 15 *M* sodium dihydrogen phosphate
1 vol 0 15 *M* sodium pyrophosphate
'*P*' suspension
'*E*' suspension

The response of the frog rectus abdominis muscle used to assay acetylcholine was affected by the presence of the drugs, especially by mecamylamine, and it was necessary, to prevent a progressive reduction in sensitivity, to adopt a routine of regular repeated washing and resting of the tissue after each estimation

Contrary to the results reported here, a brief note[3] appeared earlier indicating that mecamylamine can inhibit acetylcholine formation, but recent discussion with the authors has clarified the position. The suggestion arose from preliminary experiments in which a soluble choline acetylase was used, prepared from an acetone powder of rabbit brain, the acetylcholine formed being estimated colorimetrically Mecamylamine was used in amounts equimolar with choline, and since the assay method adopted necessitates a high choline concentration (10^{-2} *M* or more) there was a serious possibility that the inhibition was non-specific Subsequent studies with other secondary amines confirmed this and the work was discontinued

In their investigation of pempidine, Corne and Edge[4] showed that a large dose (10 mgm) could reduce by 40 per cent the acetylcholine output from the cat's perfused superior cervical ganglion in response to pre-ganglionic stimulation Their experi-

26539†	10^{-4}	100, 100	95, 95
HC-3	10^{-4}	47, 80, 40, 57, 50	83, 105, 101, 100, 117

* Used as hydrochloride
† Used as tartrate

ments were of short duration when compared with the time required to show the reduction produced by *HC*-3 on the same preparation[1] The effect seen by Corne and Edge could well be due to a slight local anæsthetic action[5], common among amines

Thus the experiments described here give no support to the hypothesis that the ganglion-blocking agents mecamylamine, pempidine or 26539 act, even in part, by inhibition of acetylcholine formation They affect neither the simple choline acetylase activity of preparation '*E*' nor, in preparation '*P*', the additional limiting step of choline entering the particles

I am grateful to Dr A Spinks, Imperial Chemical Industries, Pharmaceuticals Division, for the pempidine and compound 26539 used in this work

PLANT PHYSIOLOGY

Effect of Gibberellic Acid on the Initiation of Flowers and Runners in the Strawberry

A NUMBER of long-day responses are induced by the application of gibberellic acid to plants growing in short days These include the promotion of stem elongation and flower induction in long-day plants[1] , inhibition of flower initiation in some short-day plants[2] , and delay in the onset of autumn colouring and leaf-fall, and renewal of shoot-growth in woody plants[3] In the strawberry, flowers are initiated under short-day conditions and branch crowns are formed in the axils of the leaf petioles, which are short and prostrate During long days, flowers are seldom initiated, runners are formed in the leaf axils and the petioles are long and upright It has been suggested by one of us[4] that this greater vegetative vigour is the result of the production during long days of a growth-promoting hormone The present experiment demonstrates that gibberellic acid can act as a substitute for this natural product

Gibberellic acid was applied at 100, 50, 25, 12 5 and 0 p p m to plants of Talisman growing in pots in a glasshouse under natural short days from September 4 until November 19 Temperature was not accurately controlled, but the minimum night temperature fell from the range 55–60° F in the earlier part of the experiment to 50–55° F during November Ten plants were used for each treatment and the gibberellic acid solution, with 'Agral' added as a wetter, sprayed on until run off For the first three weeks application was weekly, and afterwards at fortnightly intervals

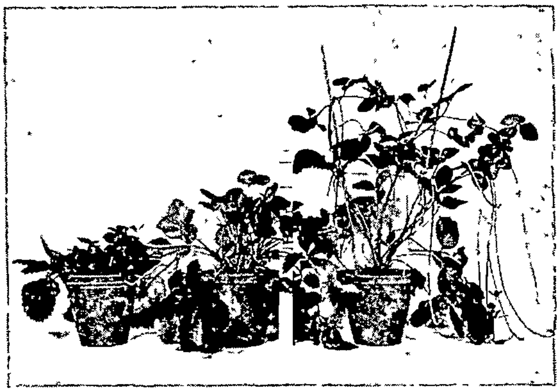

Fig 1 Effect of fortnightly applications of gibberellic acid to strawberries under short days at 25 p p m and 100 p p m Untreated control on the left

The first effects of treatment appeared after about twelve days as a slight paling of the youngest leaves and a very upright growth of the petioles Increase in length of the internodes of the main stems occurred a little later Table 1 shows that the length of the main stem measured over nine internodes from the leaf emerging at the start of treatment was directly proportional to the concentration of gibberellic acid applied In the controls, the increase in length of the main stem over this period was so small that no satisfactory measurement could be made , it was, however considerably less than that found at the 12 5-p p m level Under the conditions of this experiment, length of petiole did not increase with concentration of gibberellic acid to the same degree In all treated plants the petioles were considerably longer than in the controls, but the response at 12 5 p p m was only a little less than that at 100 p p m The difference in response between petioles and stems is illustrated in Fig 1

During November, runners which had failed to emerge were found in the axils of the leaves of some of the treated plants After the removal of two plants from each treatment for dissection, the remainder were reduced to four main stems each and transferred to a lighter and warmer glasshouse, in which the minimum night temperature was in the range 60–65° F , to encourage the emergence of the runners. As a further aid, the tips were removed from two stems on each plant To determine whether the emergence of runners was controlled by length of day in spite of the application of gibberellic acid, half the plants were given a light break from 10 p m until 2 a m using 60-W incandescent lamps suspended 2 ft above the bench, and the other half were given short days with similar illumination during the afternoon from 2 p m until 6 p m

Runners started to emerge immediately under the new conditions, and after twelve days runner emergence was recorded All the runners counted had been initiated in the natural short-day conditions of the first glasshouse The number of runners emerging was not affected either by photoperiod or by tipping, and their failure to emerge earlier must have been the result of poor growing conditions In Table 1 these secondary treatments have been combined and production of runners is shown as the mean number of runners produced per crown at each level of application The appearance of the plants three weeks after transfer to the warmer glasshouse is shown in Fig 1

Table 1

Gibberellic acid (p p m)	Inflorescences per crown	Runners per crown	Mean length of main stems (mm)
None	1 00	0 00	—
12 5	0 58	0 25	14
25	0 25	1 16	41
50	0 00	1 22	115
100	0 00	1 59	289

Records for flower initiation were obtained, first from the plants dissected at the time of transfer to the second glasshouse, and second by counting inflorescences emerging after transfer to this house All the inflorescences counted had been initiated during the course of the natural short-day treatment, these are shown in Table 1 as the mean number of inflorescences per crown at each treatment-level

All these results, namely, increase in length and upright growth of the petioles, initiation of runners instead of branch crowns, and suppression of flower initiation, are typical of the response of this plant to long-day conditions It would seem that gibberellic acid can serve as a substitute for a growth-promoting hormone produced naturally under long-day conditions On the other hand, the fact that complete suppression of flower initiation and the highest level of runner production was not reached until the concentration of gibberellic acid was such that it caused abnormal elongation of the main stems would suggest that the long-day growth-promoting hormone and gibberellic acid are not identical, although they may be closely related

The gibberellic acid solution used in this experiment was kindly supplied by Plant Protection, Ltd

Effect of Indole Acetic Acid and α-Naphthalene Acetic Acid on the Growth, Flowering and Fruit Set in Sweet Potato

Sweet potato (*Impomoea batatas* (L) Lam) is cultivated for its tuber and its foliage, which is used as cattle food It is usually propagated either by the tuber slips or stem cuttings, in India the latter method is usually followed Hernandez *et al*[1] reported that the tubers when dipped momentarily in 2,4-D at 10 p p m produced a significantly larger number of plants than the control, but they did not study the effect of the chemical on stem cuttings or on tuber yield. Howell and Wittwer[2,3] observed that 2,4-D sprays induced better flowering in sweet potato Mikell[4] found that 2,3,5-triiodobenzoic acid, 2,4-D and α-naphthalene acetic acid failed to induce any flowering when the plants were treated either by the wick method, foliage spray or soil application

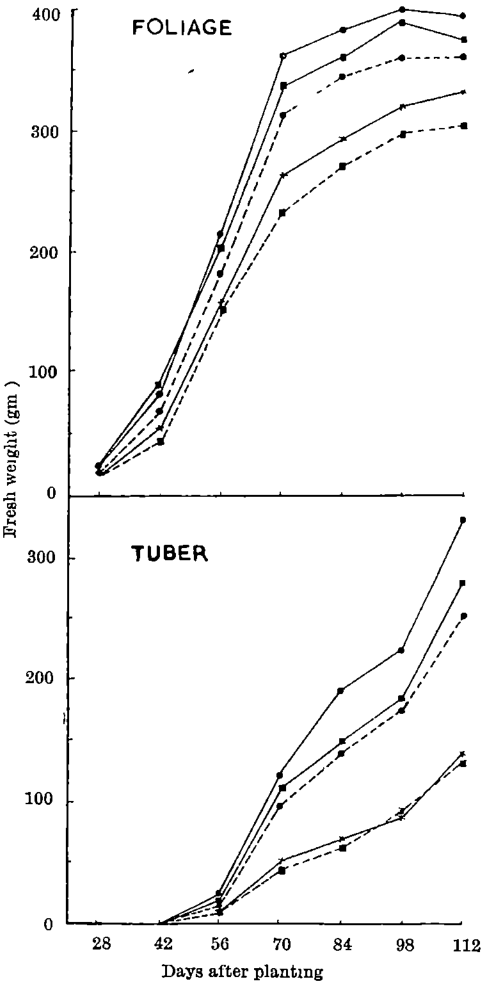

Fig 1 The influence of indole acetic acid and naphthalene acetic acid on the growth of foliage and development of tubers in sweet potato, as indicated by their fresh weight Indole acetic acid ●—●, 25 p p m , ●---●, 10 p p m Naphthalene acetic acid ■—■, 1 p p m , ■---■, 25 p p m ×—×, control

Studies were undertaken by us recently to find out the effect of two plant-growth regulators, namely, naphthalene acetic acid and indole acetic acid, on the growth, tuberization, flowering and fruit set in sweet potato Stem cuttings of uniform thickness and 12 in in length were selected from a local white variety of sweet potato The basal ends were immersed up to one inch in various concentrations of the growth regulators in water and in water alone as control When the cuttings were immersed for 24 hr in water, root development was inhibited, this did not occur after 12 hr immersion Subsequent studies were therefore made by treating the stem cuttings for 12 hr only The treated cuttings were washed thoroughly with tap water and planted in a well-prepared field on ridges with a spacing of 24 in × 12 in , 60 cuttings were planted from each treatment The plants were maintained with periodic irrigation and weeding, following the local practice

Observations on the growth of foliage, tuberization, flowering and fruit set were made at intervals. Three plants were selected at random from each treatment and the growth of shoot and root measured, the amount of tuberization was recorded by carefully digging out the plants, washing the tubers free from soil and taking the fresh weight Representative samples of the foliage and tubers were collected and the dry weight and moisture percentage estimated The rates of growth of foliage and roots in terms of their average fresh weights are shown in Fig 1 All the treatments, except α-naphthalene acetic acid 25 p p m, were found to cause better growth of foliage and tuberization, as compared to the controls Among the treatments, indole acetic acid 25 p p m gave the best results In general the chemical treatments hastened the growth of foliage, except in the case of 25 p p m naphthalene acetic acid, where there was a definite reduction in the weight (Fig 1) The treatments produced no significant difference in the moisture content of foliage or tubers The tubers in plants treated with indole acetic acid were characterized by linear developments, whereas with naphthalene acetic acid no such effect was observed

All the treated plants flowered earlier and comparatively more than in the controls There was also more fruit set in all the treated plants, indole acetic acid at 10 p p m giving the best results (Table 1) The seeds on maturity were collected separately and on testing were found to germinate 100 per cent, giving rise to normal plants

Table 1 THE EFFECT OF INDOLE ACETIC ACID (IAA) AND NAPHTHALENE ACETIC ACID (NAA) TREATMENTS ON THE FLOWERING AND FRUIT SET IN SWEET POTATO

Treatment (p p m)		First flowering after (days)	Average No of flowers per plant	Average fruit set per plant	Fruit set (per cent)
Control	0	79	80	*	—
IAA	1	55	136	24	17 6
	10	50	180	38	21 1
	25	57	115	19	16 5
NAA	1	71	96	16	16 6
	10	64	121	14	11 6
	25	65	111	10	9 0

* Occasionally one or two fruits were found set in a few plants, which might be due to open pollination

Seed setting in sweet potato seems to be rare under natural conditions[5,6] The results obtained in the present work indicate the possibility of increasing the foliage and tuber yields as well as increasing the flowering and fruit set by treating the stem cuttings with plant-growth regulators before planting Further studies are in progress

ANIMAL PATHOLOGY

Effect of Proflavine on the Formation of the Virus of Foot-and-Mouth Disease and its Infective Ribonucleic Acid in Pig Kidney Tissue Culture Monolayers

PROFLAVINE inhibits the growth of bacterial viruses by blocking some process or processes connected with the formation of the infective virus particle from its sub-units Antigens, specific to the virus, are still synthesized in the presence of proflavine although fully infective virus particles are not produced These observations have also been made with some animal viruses (vaccinia[1,2], fowl plague[3], poliomyelitis[4]) The action of proflavine is regarded as being due to the inhibition of cytoplasmic protein synthesis, but Dulbecco and Vogt[5] have shown that low concentrations of proflavine induce mutations in the virus of poliomyelitis, so the compound probably has some action on the nucleic acid of this virus

As it has recently been shown[6] that infective ribonucleic acid can be obtained from pig kidney tissue culture cells infected with the virus of foot-and-mouth disease before fully infective virus is formed, it was considered that it would be of interest to study the effect of proflavine on the synthesis of infective virus and its ribonucleic acid in this cell system Pig kidney cells grown in monolayers were infected with strain 997 (type *C*) of the virus (10^6 *ID*50 on each monolayer of 2×10^6 cells) After 30 min adsorption the sheets were washed, medium containing 0–6 μgm proflavine per ml added and the cultures incubated at 37° C for 4 hr The entire cultures were then either (*a*) treated with 0 1 per cent sodium dodecyl sulphate[7] to disrupt the cells and the released virus titrated in 7-day unweaned mice, or (*b*) treated with phenol[8] at 2° C and the infective ribonucleic acid titrated in pig kidney cell monolayers In view of the photodynamic action of proflavine on the virus of foot-and-mouth disease[9], all the experiments were carried out in the absence of light or in subdued lighting conditions The results in Table 1 show that a marked inhibition of infective virus synthesis occurred when the medium above the infected monolayer contained proflavine As little as 1 μgm proflavine per ml reduced the infective virus titre thirty-fold, whereas the infective ribonucleic acid titre was unaffected by this concentration When the proflavine concentration was increased to 2 μgm /ml the virus titre was reduced by a factor of one thousand but the ribonucleic acid titre was reduced only ten-fold It is clear, therefore, that proflavine exerts a much greater effect on the formation of fully infective virus than it does on the synthesis of the infective ribonucleic acid

Infected monolayers incubated in the presence of 2 μgm proflavine per ml showed cytopathogenic

Table 1 EFFECT OF PROFLAVINE ON THE SYNTHESIS OF VIRUS AND INFECTIVE RIBONUCLEIC ACID BY PIG KIDNEY CELLS INFECTED WITH FOOT-AND-MOUTH DISEASE VIRUS

Proflavine (μgm /ml)	Virus titre (log *ID*50/ml)	Infective ribonucleic acid (log *ID*50/ml)
0	6 8	2 7
0 5	6 3	—
1 0	5 3	2 6
1 5	4 4	1 7
2 0	3 8	1 5
3 0	3 8	0 4
4 0	3 3	Non-infective
6 0	2 8	Non-infective

changes similar to those seen in duplicate virus-infected cultures incubated in the absence of proflavine. Although these changes occurred more rapidly in the monolayers free from proflavine, with medium containing 2 µgm./ml. the cells were beginning to show cytopathogenic changes after 4 hr. and were completely off the glass after 24 hr. When the concentration of proflavine was increased to 10 µgm./ml., however, no change was apparent in 4 hr. although the cells had rounded and partly left the glass after 24 hr. Cell sheets which had not been infected with virus were unaffected by medium containing 10 µgm./ml. in 24 hr.

The action of proflavine in inhibiting the synthesis of infective virus is very rapid. The results in Table 2 show the effect of adding 2 µgm. proflavine per ml. to virus-infected monolayer cultures at various intervals after infection and then continuing the incubation so that each culture was incubated for a total of 4 hr. following infection. Virus synthesis was stopped almost immediately, as shown by the corresponding titres in columns 2 and 3 of Table 2.

Table 2. EFFECT OF PROFLAVINE ON THE PRODUCTION OF INFECTIVE VIRUS IN PIG KIDNEY CELL MONOLAYERS

Time after infection (hr.)	Virus titre at time of adding proflavine (log *ID*50/ml.)	Virus titre at 4 hr. (log *ID*50/ml.)
0·5	2·5	2·5
1·0	2·3	3·0
1·25	2·3	3·0
1·5	3·0	3·3
1·75	3·8	4·5
2·0	4·3	4·5
3·0	6·3	6·0

Although the culture fluids obtained 24 hr. following infection of pig kidney cell monolayers with virus fixed complement with the type-specific antiserum, the culture fluids obtained from similarly infected monolayers which had been incubated in the presence of 2 µgm. proflavine per ml. did not fix complement. This effect of proflavine must be on the virus-cell system, as the complement-fixing activity of virus suspensions was unaffected by treatment with the same concentration of proflavine. These experiments lead to the conclusion that at low concentrations proflavine can exert a differential inhibiting effect on the formation of viral protein, with the result that infective ribonucleic acid is still formed whereas the synthesis of infective virus is greatly inhibited.

We wish to thank Dr. I. A. Galloway for bringing to our notice the photodynamic action of proflavine on the virus and Mr. B. Cartwright for carrying out the complement-fixation tests.

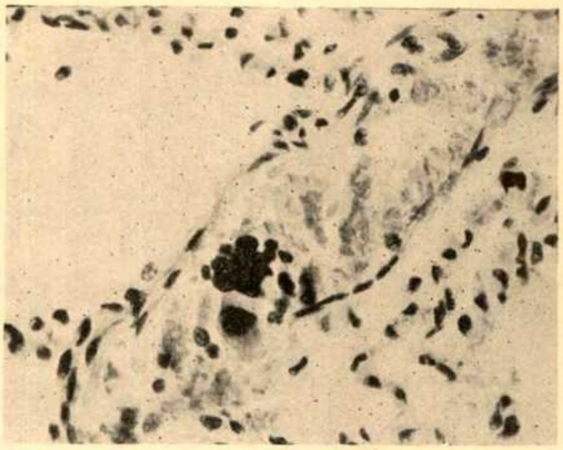
A Possible Explanation of the Formation of Long Platelets from Pulmonary Megakaryocytes

THE purpose of this communication is to suggest a possible explanation of the formation of the elongated sausage-shaped, sometimes bizarre long platelets that are occasionally encountered in human blood smears. Since Bizzozero[1] first described the platelets as a distinct entity in 1882, much has been conjectured as to the source and mechanism of their formation. Before Wright[2] described the formation of blood platelets from bone marrow megakaryocytes in the marrow sinusoids in 1910, the thrombocytes were assumed to be formed from disintegration of erythrocytes and leucocytes. Howell and Donahue[3] unsuccessfully attempted to show by lung perfusion studies in 1937 that the thrombocytes were formed from megakaryocytes. The latter they believed originated in the lungs. More recently, Humphrey[4] has added chemical evidence to the hitherto purely morphological evidence that the platelets are derived from the megakaryocytes. But according to Wintrobe[5]: "The mechanism of production of platelets from the cytoplasm of megakaryocytes is by no means clear."

Unaware of the studies of Howell and Donahue, Sharnoff and Kim[6] recorded their observations on pulmonary megakaryocytes which appeared to



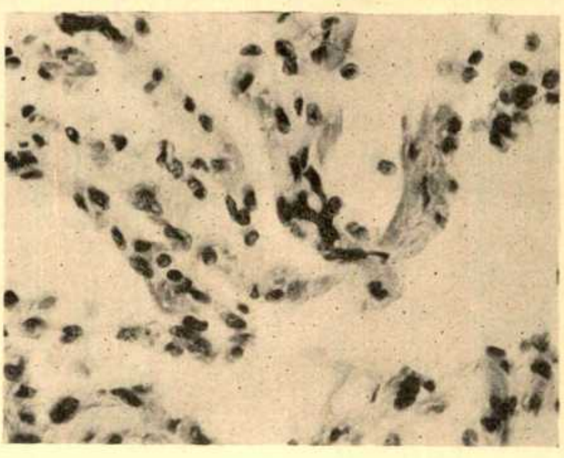


Fig. 1 (above). Megakaryocytes in human pulmonary pre-capillary blood vessel (× 414). Fig. 2 (below). Megakaryocyte dividing in the capillary anastomoses of the human lung. (× 414)

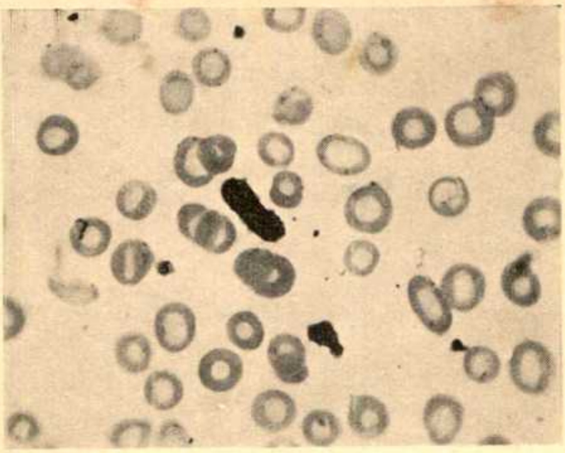
(*Photograph: Robert T. Duckworth*)



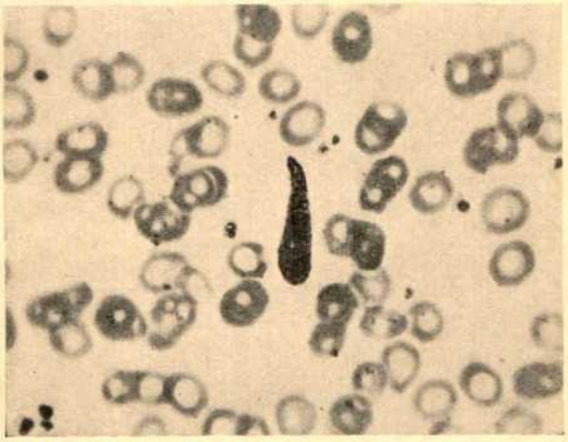


Fig. 3 (above). Sausage-shaped long human blood platelet (×830, oil immersion). Fig. 4 (below). Long human blood platelet (× 830, oil immersion)
(*Photograph : Robert T. Duckworth*)

indicate that the presence of these cells in mammalian lung vessels is a normal phenomenon, where they appear to break up into platelets. Their studies demonstrated that the cells seen in the lung vessels were identical histochemically and morphologically with the bone marrow megakaryocytes and that they were transported from the bone marrow to the lungs by the venous circulation. Their histological observations indicated that the megakaryocytes are too large to pass the lung capillaries intact (Fig. 1) and that the cells appeared to break up in the capillary anastomoses by the pumping action of the right heart ventricle (Fig. 2). The megakaryocytes appeared to be moulded into the shape of the capillaries and divided by their anastomoses. It was postulated that in assuming the capillary outline by being pressed into the vessels the cells can emerge as casts of the vessels, thus occasionally being encountered in blood smears as long platelets (Figs. 3 and 4). It can be further postulated that further break up of these elongated platelets may occur in the eventual passage through the peripheral capillary vascular system. It also would appear that the elongated forms are more commonly seen in individuals with high platelet counts where the platelets appeared freshly formed.

In summing up, it would appear that long platelets may be formed from pulmonary megakaryocytes by being pressed into the lung capillary blood vessels and emerge as casts of the same.

This work was supported in part by a grant form the Westchester Heart Association.

A Seasonal Rhythm in the Presentation of Bone Sarcoma in Man

FROM a study of the ætiology of osteogenic sarcoma in man carried out during the past four years, it has been possible to demonstrate certain trends in the age and sex incidence of these relatively rare neoplasms[1,2]. Probably the most interesting features are the observations that the tumours tend to arise at an earlier age in females among adolescents, and also the higher incidence of tumours of the arm and pectoral girdle at an earlier age compared with those of the leg and pelvis in juveniles of both sexes. On comparison of the mean ages of groups of osteogenic sarcomata in adolescent males and females, whether for the whole skeleton or for individual bones, the differences of mean ages (male minus female) are seldom statistically significant, nevertheless they are almost invariably in the same direction.

The most likely explanation of these differences in age, sex and site would seem to lie in the relatively advanced skeletal growth of girls, and in the general cephalad-caudad sequence of growth progression. It is well known of course that the majority of osteogenic sarcomata of adolescents arise in the metaphyses of the major long bones, although this feature of consistent anatomical location is not so clearly defined in tumours of persons over the age of fifty-five years, among whom Paget's osteitis deformans forms the background of the majority of cases—at least in Great Britain[1]. In this older age-group the trends mentioned above cannot be shown to occur.

Among the characteristic patterns of juvenile bone growth is a seasonal rhythm with the maximum velocity peak in the spring months of April, May and June. The literature on this subject has been discussed by Brody[3] and by Tanner[4], the former author comparing the human growth-cycle with other photoperiodic phenomena of mammals and birds. In discussing this topic Tanner[4] states that the monthly height-gain average for the period April–June may be as much as 2–2½ times that of the months October–December.

In the light of these considerations an analysis was made of the case-histories of 102 osteogenic sarcomata included in the records of the Bristol Bone Tumour Register ; and from among these were eventually separated a group of 40 tumours of long bones all in persons less than 30 years old. This small series was supplemented by the addition of a further 34 cases from four other hospitals, details being furnished by the consultant surgical staffs and medical records officers of these institutions. These 74 cases have been plotted in Fig. 1 according to the month when they first complained of any definite symptom directly related to their subsequent clinically apparent tumour. This initial symptom was most often bone pain—less frequently pain and local swelling. The data are cumulative over a period of 18 years (1941–58). It will be noted that the incidence of tumours is greater during the months June–November inclusive, when the monthly average was 9·2 tumours per month, than for the months December–May, when the average of 3·2 tumours per month was encountered. (This difference is statistically significant: $\chi^2 = 16{\cdot}33$; $P < 0{\cdot}01$.)

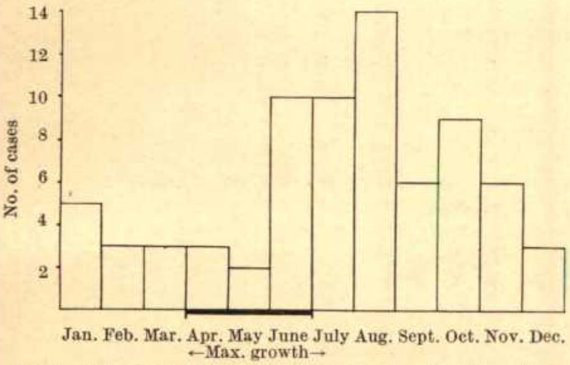

Fig. 1. Osteogenic sarcoma—long bone cases only, all less than 30 yr. old. Plotted according to month of presenting symptom: 'summer' period (June–November, inclusive), 55 cases; 'winter' period (May–December, inclusive), 19 cases; total, 74 cases

The same data were re-examined by annual groups (1943–58), but excluding 4 tumours which were recorded for the years 1941–42. Although the numbers each year are small, the trend of numerical preponderance in 'summer' still appears. The annual distributions are shown in Fig. 2. In 13 of 16 recorded years the number of tumours presenting during the 'summer' period is greater than that encountered for the corresponding 'winter' period. (These differences are again significant, $t = 3{\cdot}04$; $P < 0{\cdot}01$.)

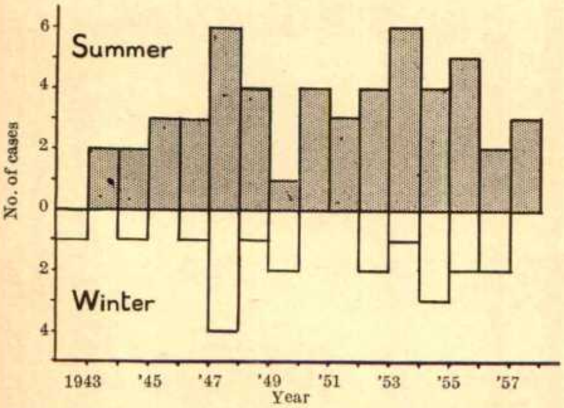

Fig. 2. Osteogenic sarcoma—same series as Fig. 1, plotted by years according to timing of presenting symptom. Comparing numbersin 'summer' and 'winter' periods the difference is statistically significant ($P < 0{\cdot}01$)

For brevity's sake it may simply be stated here that these differences in monthly incidence do not appear in a similar analysis of a series of 55 osteogenic arcomata in older persons more than thirty years of age. This negative result might be expected in view of the modified ætiology of bone tumours of this age-group.

It may be added that this increase in 'summer' incidence in the presentation of sarcomata holds for either sex when the whole series is so sub-divided. Moreover, it exists in each of the four major component groups of cases which were derived from Bristol, London, Manchester and Glasgow. (It has also appeared in a further group of 15 patients, details of whom were received too late for inclusion in the present study.)

With the material available it is not yet possible to define the shape of the 'summer' peak or its precise timing; but in all probability it appears sometime during July and August, that is, about 3 months after the spring peak in the bone-growth velocity curve.

In adolescents the growth of bone in length with subsequent remodelling continues throughout the year, and is responsible in some obscure way for the basic monthly level of incidence of bone sarcoma. The probable size of the lag period between the two peaks of spring growth and presentation of bone sarcoma would seem however to suggest a biological linkage, especially in the light of collateral evidence which relates these two phenomena. Inquiry has not indicated any extraneous factors which might otherwise account for this abnormal distribution of tumour presentation during the yearly cycle.

Dr. Grace M. Jeffree has assisted in this work by examining the case records of the Bristol group, and Mr. G. M. Clarke has given invaluable advice with the statistical treatment of the material.

Details of patients have been freely given by the contributing members of the Bristol Bone Tumour Registry: by Mr. H. Jackson Burrows, and the Medical Records Officer and Committee of the Royal National Orthopaedic Hospital, London: by Dr. Ralston Patterson, of the Christie Hospital and Holt Radium Institute, Manchester: by Mr. Rowland Barnes, and Dr. Mary Catto, of the Glasgow Western Infirmary: and by Dr. Constance A. P. Wood, of the Hammersmith Hospital, London.

This investigation was supported by grants from the British Empire Cancer Campaign.

PLANT PATHOLOGY

Needle Transmission of a New Maize Virus

The rough dwarf disease of maize ("Nanismo Ruvido del Mais") has been known from Italy since 1949[1] and has lately been reported from Israel too[2]. The symptoms of the disease and its epidemiology were described in both countries[3,4] with the assumption that the causal agent is a plant virus. Since no experimental transmission of the disease had been accomplished, it was not certain that the agent was a virus. All attempts to transmit the disease by rubbing sap into maize leaf blades, using various abrasives, have failed. Transmission trials with a local dodder species, *Cuscuta eigii* Sroëlov, also proved negative.

Recently, however, transmission has been achieved for the first time by the following method. Hybrid maize plants showing severe dwarf symptoms were ground in a meat mincer, the sap squeezed through a cheese cloth and then centrifuged for 5 min. at 3,000 r.p.m. The supernatant fluid was injected by means of a 1 c.c. tuberculin syringe into the stalks of 3-week-old hybrid maize seedlings (Neve Yaar hybrid 22, single cross) grown under insect-proof conditions. The dosage was about 0·2 c.c. per seedling divided into 5 punctures at different sites. A control series was injected with healthy sap in the same manner. Three out of twelve plants injected with diseased sap, in two different series, developed both stem and leaf symptoms (including the rare symptom of split blade) within two months. As this was done in winter, without artificial illumination, it is believed that during summer the development of symptoms should be faster. Infectivity of the sap, when frozen, was retained for at least 24 hr. Since the virus is not transmitted by seed, the reliability of the test seedlings is unquestionable.

Similar cases where mechanical transmission of plant viruses could be obtained by needle inoculation only are those of sugar beet curly top[5] and clover wound tumour[6]. Both these viruses are leaf hopper-borne and, at least in the case of curly top, the virus is believed to exist in the phloem which might be considered inaccessible to ordinary surface rubbing[7]. In the case of the maize rough dwarf virus it may be inferred from Biraghi's studies[8] on the pathological anatomy of the disease that the virus tends to inhabit the phloem, though its natural vector is still unknown.

BIOLOGY

Black Marlin in British East African Waters

RECENTLY I stated that only the striped marlin (*M. audax*) had been caught by the East African Marine Fisheries Research Organization, and records of the black marlin in these waters were of doubtful value[1].

Since that communication I have taken two black marlin while using a longline 10 miles off the Tanganyika coast at latitude 8° S.; the fish were of standard length 2,130 and 2,325 mm. and weight 125 and 135 lb. respectively. On capture and comparison the differences from the striped marlin were most obvious—a very low dorsal fin, deep body, steeper head profile and 'rigid' pectoral fins. Proportional measurements confirmed the field observations and an examination of the morphology of the pectoral girdle showed it to be similar to that described by Morrow[2] as diagnostic for the black marlin. Colour was as follows: in life, upper two-thirds of body and fins blue-grey and lower third of body white, the join between the two colours being distinct; on death, the colour fades rapidly and the body and fins become grey, a little darker above. There are at no time any signs of the vertical stripes or brilliant cobalt blue coloration of the striped marlin.

Morrow (personal communication) reveals that his Pemba specimen of marlin weighed 159 lb. at 2,151 mm. and *not* 259 lb., as reported in his paper on East African fishes[3], and thus the record is validated as that of a black marlin.

In a recent paper on marlin taxonomy, Morrow[4] examined the pectoral girdle of the remains of Playfair's type specimen of *H. brevirostris* from Zanzibar and found it to correspond exactly to that of the black marlin[2]. Thus the position of this fish is clarified, the original proportional measurements and later examinations of the type specimen being insufficient for exact identification as stated earlier[1].

The black marlin is rare in this area, only two having been caught hitherto by this Organization, as compared with eighty-four striped marlin.

A Chimæric Duck with the Head of a Chick

IT is well known that the chick embryo fails to produce detectable antibodies against various foreign antigens, so providing a favourable environment for culturing viruses and transplanting various tissues of

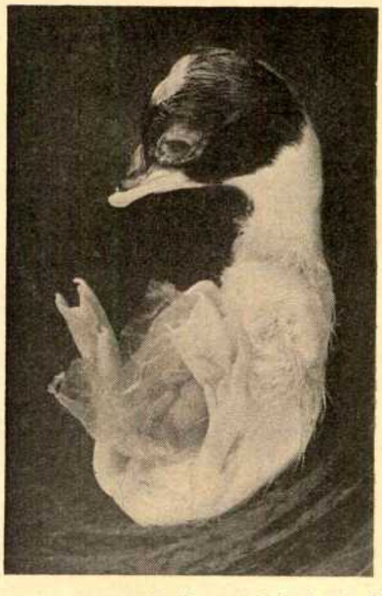

Fig. 1. A duck embryo with the grafted head of a chick, after 28 days of incubation

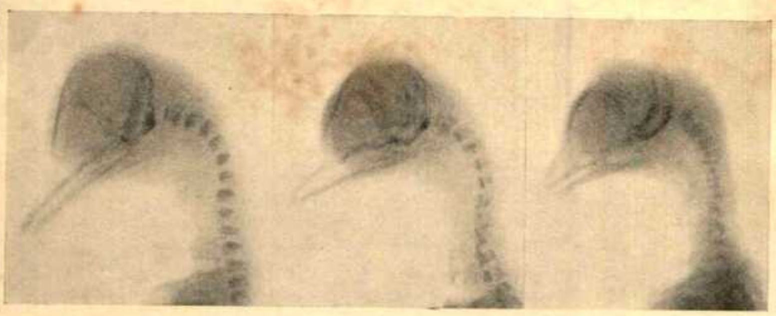

Fig. 2. X-ray photographs of the skulls at hatching. Left, a duck; centre, the chimæra (Fig. 1); right, a chick. Note the striking similarity between the duck and the chimæra, except the upper beaks

birds and mammals[1]. It is also known from the work of Billingham *et al.*[2] that "actively acquired tolerance", the power to react immunologically against foreign homologous tissue cells with which they have been inoculated in fœtal life, is never developed by birds and mammals, or developed only to a limited degree. A renewed interest in heterotransplantation stimulated us to graft various types of tissue primordia between embryos of two different genera of birds, the chick (Galliformes) and the duck (Anseres). Using the same combination, Hašek and his co-workers were not successful in inducing a tolerance for skin heterografts between young obtained by embryonic parabiosis[3] or between young injected with each other's spleen or bone marrow cells shortly after hatching[4]. On the other hand, some cases of limb bud grafting during early days of incubation by Eastlick[5] seem to indicate a certain degree of tolerance, although his experiment was carried out from a point of view of tissue incompatibility in heterologous combination[6].

As one of an experimental series of reciprocal chick–duck heterotransplantation, the grafting of the forebrain region following the technique originally developed by Martinovitch on the chick embryos[7] was performed. The heads were severed just behind the optic vesicle, and were exchanged between the embryos of white duck and a coloured breed of chick, Barred Plymouth Rock, at stages corresponding to Hamburger and Hamilton's stage 10–11. These stages were reached by the chick after about 42 hr., and by the duck after about 55 hr. of incubation at 37·5° C. While the chick embryos grafted with duck heads did not survive for long, one of the duck embryos with the head of a chick survived through the whole length of its embryonic life, 28 days of incubation (26 days after grafting). Fig. 1 illustrates this chimæric embryo.

In size and in growth of feathers, the chimæra resembles the average duck embryo at hatching. However, the umbilical ring was still large and the withdrawal of the yolk into the body cavity had not begun. The host duck was found by examining the gonad to be a male. The contribution made by the graft was represented by the upper beak and eyes, the under-developed crest and the melanophores. The latter spread over both lateral surfaces of the head far caudad beyond the auditory opening, leaving unpigmented only the feathers on a mesial portion in the occipital region. It was clear that an extensive migration of the chick melanoblasts had taken place because the ear region is obviously of duck origin. At the top of the head, there was a round area where no feathers and melanophores were present. The cause of this is not clear. When an X-ray photograph of the skull of the chimæric embryo was compared with those of normal duck and chick embryos at hatching (Fig. 2), it proved to resemble the former much more than the latter. This indicates that skull of the chimæra was derived mainly from duck head mesenchyme.

While this grafting was being undertaken, Martinovitch published the results of grafting by the same method and combination[8] in which considerable abnormalities were reported. Our efforts to hatch these chimæras have been unsuccessful, and the prospect is rather dubious (Martinovitch, P. N., personal communication). However, a greater possibility of survival could be expected in the combinations of genetically more closely related species.

The Benthos of Soft Sea-bottom in Arctic North America

QUANTITATIVE surveys of the benthos of soft sea-bottom were made in Baffin Island, N.W.T., during 1954 and 1955, in Greenland during 1956, and in Foxe Basin, N.W.T., during 1957, as part of expeditions organized by the Arctic Institute of North America and the Fisheries Research Board of Canada. These surveys, and others made previously in Greenland, show that *Macoma calcarea* communities[1] with standing crops generally greater than 200 gm./m.[2] (fresh weight) occur in shallow water to about 50 m. depth in many localities in arctic North America. Other communities, some with very small crops, also occur in shallow water under localized, special conditions. They are the *Venus fluctuosa*, *Portlandia arctica* and *Chiridothea sabini* communities. The soft-bottom benthos in water deeper than about 50 m. forms at least two communities, the Foraminifera and *Arca-Astarte crenata* communities, with standing crops generally less than 100 gm./m^2.

The distribution of these communities can be related to the environmental conditions. In these arctic regions the water at depths greater than 50 m. has permanently low temperatures, which may either be just above 0° C. or below. Ekman[2] calls regions with such temperatures "low-arctic" and "high-arctic" respectively. However, overlying the deep water is an annually insolated layer, the temperatures of which may occasionally rise to 5° C. or more in summer. Low-arctic conditions can, and often do, occur temporarily at the surface over high-arctic deeper water. The two terms can apply to temperature zones arranged vertically in the sea, as well as zoogeographical regions. As such they are convenient for an ecologist to use, but their significance is mainly as a guide to the temperatures; they imply nothing about the dynamics of the oceanographic conditions, unlike other systems of naming the arctic marine regions[3].

The *Macoma calcarea* communities have only been found where sea temperatures are permanently or seasonally low-arctic. Thus they occur in surface insolated water in the regions farthest north, but may extend deeper elsewhere, for example, Spitsbergen, Iceland[1]. They have a wide geographical range, apparently because some of the component species can adapt their breeding season to the time of year when appropriate temperatures occur, namely, in summer in the Arctic, in winter in warmer areas. The *Venus fluctuosa* and the *Portlandia arctica* communities appear to be restricted to certain bottom sediments within the low-arctic environment: types of coarse sand and fine mud, respectively. The *Chiridothea sabini* communities have only been found in two localities, in which the most obvious common environmental factor is very low summer temperature, that is to say, permanently high-arctic. The two deeper water communities occur below the depths affected by insolation where temperatures may be either low- or high-arctic.

Scattered dredge collections from Greenland to Alaska suggest that communities of *Macoma calcarea* are very widely spread in shallow water throughout arctic North America, but are replaced by other communities in deeper water. This pattern of vertical zonation appears to be very common.

An account of the collections and a more detailed discussion of the ecological and zoogeographical concepts mentioned here is being prepared for publication. Tables listing the species collected, and their numbers and weights per grab haul, are included in a doctoral thesis[4] deposited in the Redpath Library, McGill University, Montreal.

CYTOLOGY

Nuclear Deoxyribonucleic Acid Content and Endopolyploidy in the Meristem of Onion Roots

PHOTOMETRIC analysis of the deoxyribonucleic acid content of nuclei would afford an interesting approach to the problems connected with polyploidy, polyteny and endomitosis, our knowledge of which is still fragmentary. It would also help us to understand the evolutionary processes and trace the relationships of species. If, in accordance with the hypothesis of deoxyribonucleic acid constancy, there is a strict correlation between the deoxyribonucleic acid content and the number of chromosomes, or more exactly the number of chromonemata, measurement of deoxyribonucleic acid would be the easiest way of studying polyploidy, polyteny and endomitosis, particularly in the interphase or prophase nuclei where the chromosome numbers cannot be counted. Evolutionary processes involving polyploidization from one species to another close one can be traced by means of photometric analysis, as the deoxyribonucleic acid content of the sperm or of the normal diploid nucleus appears to be characteristic of a species. The utilization of deoxyribonucleic acid content in problems of evolution is well illustrated by Hughes-Schrader's[1] work on a number of closely related species of mantids the karyotypes of which are not analysable by the usual methods of comparative cytology. The deoxyribonucleic acid content of the spermatids of two species, one having twice the number of chromosomes as the other, was the same, agreeing well with cytological studies which led to the conclusion that redistribution of chromosomal material rather than polyploidy was involved in the evolution of these species. On the other hand, in two other close species the deoxyribonucleic acid ratio of the spermatids was very near 1 : 2, indicating that polyploidy had played a part in their evolution.

During the course of studies on the deoxyribonucleic acid content of nuclei in the meristem of onion roots[6] in one of the central rows of cells which later become central vessels an unusual prophase was found in one of the roots. Each of its chromosomes showed very distinctly two relationally coiled strands. In these sections of roots fixed in acetic acid/alcohol (1 : 3) pairs of sister chromatids at prophase usually appear as single strands. Each strand in this exceptional prophase, furthermore, corresponded in thickness to a whole chromosome of a normal mid-prophase, and the former can be identified as a mid-prophase by the length and relic coiling of the chromosomes. No doubt this nucleus has a diploid complement of chromosomes with four, instead of two, chromatids each. Judged by the number of genomes, such a nucleus is essentially tetraploid. This prophase nucleus happened to be completely, or practically completely, within the section (15μ thick) in spite of its large volume of $3,638\mu^3$ (as compared with 903–$1,004\mu^3$ found in diploid mid-prophases). (The volume in μ^3 was computed as $V = 2hA/3$ where A is area in μ^2 of the largest cross-section of the nucleus measured by a planimeter from a camera lucida drawing, and h is height in μ found as the average difference of four pairs of readings from the microscope fine-adjustment screw.) The deoxyribonucleic acid content measured in arbitrary units, according to the two wave-length method of Patau[3] with modifications[6] was $\gamma = 46{\cdot}34$, almost exactly twice the mean obtained from seven diploid prophase nuclei ($\bar{\gamma} = 22{\cdot}88 \pm 0{\cdot}44$) which is here taken as the best estimate of $4C$.

Similar tetraploid prophases have, of course, been observed before in differentiated root tissue (for example, in great numbers in *Rhoeo* roots treated with indoleacetic acid[2]). What makes the present nucleus highly unusual is its location well within the meristematic part of the root. It is, however, a region in which the cells of the central rows do not ordinarily divide any more; instead, many or most of the nuclei in these rows step up their deoxyribonucleic acid content to what must be about $8C$ or more as judged by their striking combination of large size and intense staining. One of these was measured.

The value obtained, $\gamma = 41 \cdot 35$, is somewhat less than 8*C*. It probably had not finished synthesizing deoxyribonucleic acid. In sections of 15μ most of these nuclei are cut, so that when choosing the nucleus to be measured selection for small volume was inevitable. This nucleus was $1,534\mu^3$, much less than the volume of the tetraploid prophase nucleus and almost the same as the volume, $1,569\mu^3$, of a 4*C* interphase nucleus ($\gamma = 22 \cdot 87$) which was also found in a central cell row. A volume of $1,534\mu^3$ falls well outside the range of interphase nuclei of the diploid mitotic cycle. Lying in a central cell row this nucleus may have been approaching another deoxyribonucleic acid synthesis. In that event it would be more proper to call the nucleus a tetraploid interphase I rather than a diploid interphase III. (During deoxyribonucleic acid synthesis an interphase I with the deoxyribonucleic acid content 2*C* is followed by an interphase II with intermediate deoxyribonucleic acid content, and this by an interphase III with deoxyribonucleic acid content 4*C*.) The ambiguity of interpreting deoxyribonucleic acid classes in terms of polyploidy has already been stressed by Patau and Swift[5]. What can presumably safely be said in the case, say, of an 8*C* interphase is that such a nucleus must be at least a tetraploid and no more than octoploid. In central cell rows within the meristem, though in its proximal part, the nuclear deoxyribonucleic acid content is occasionally stepped up still further. These nuclei are usually too large to be included in one section. The two cut parts (identified by their position relative to eight surrounding nuclei which were also cut) of one such nucleus in neighbouring sections were measured separately. The total deoxyribonucleic acid content $\gamma = 81 \cdot 56$ is 11 per cent less than 16*C*. The difference could again be plausibly ascribed to uncompleted deoxyribonucleic acid synthesis, as the volume, $4,575\mu^3$, of this interphase nucleus was not much more than that of the 8*C* prophase.

It is noteworthy that the appearance of deoxyribonucleic acid values higher than 4*C* in the central cell row is accompanied by an almost complete disappearance of mitotic nuclei. The tetraploid prophase was the only exception observed. All other nuclei were clearly at interphase. In these cells, contrary to those of the surrounding tissue, the initiation of mitosis has been blocked, but deoxyribonucleic acid synthesis has not. Precisely the opposite situation was found by Patau[4] in the corresponding cell rows of *Rhoeo*. In these, mitotic activity also stops long before it ends in the surrounding tissue, but deoxyribonucleic acid synthesis is blocked even earlier, for, in these rows (not only in the proximal meristem but also in the elongation zone) all but a very few nuclei have the deoxyribonucleic acid content 2*C*. This means that the great majority of nuclei after their last deoxyribonucleic acid synthesis still underwent a mitosis, as this is presumably the only process capable of halving the deoxyribonucleic acid content. The fact that either of the two processes—deoxyribonucleic acid synthesis and mitosis—may be blocked first characterizes them as essentially independent of each other, even though a normal mitosis presupposes a previous deoxyribonucleic acid synthesis.

It is concluded that in central cell rows of onion roots, mitotic activity ceases deep in the meristem. Instead, endopolyploidy develops, with the deoxyribonucleic acid content going up to 8*C* or even 16*C*. One quite exceptional prophase was found in a central cell row in the meristem that presumably had the diploid number of chromosomes, with four instead of two chromatids. Its deoxyribonucleic acid content was 8*C*.

This investigation was supported by grants to the late Dr. C. Leonard Huskins from the American Cancer Society upon recommendation of the National Research Council Committee on Growth, from the Rockefeller Foundation and from the Research Committee of the Graduate School, University of Wisconsin, with funds supplied by the Wisconsin Alumni Research Foundation. My thanks are due to Dr. K. Patau for guidance.

A Partial Chemical Characterization of Maize Coleoptile Cell Walls prepared with the Aid of a Continually Renewable Filter

The present work was undertaken with the objective (*a*) of preparing plant cell-wall fragments free of contamination by intact cells, cytoplasm, plastids and other cell inclusions, but containing most of the constituents of the cell wall, including proteins, and (*b*) of characterizing such a cell-wall fraction chemically. The procedure differed from those previously reported in that a filtration technique was employed for purification of the cell-wall fragments and in that isolation was accomplished in an essentially non-aqueous media. It is believed that the filtration technique may prove generally useful in the preparation of cellular components where purification by differential or gradient centrifugation proves impossible. Previous reports of the chemical composition of plant cell-wall tissue have been based on the residue remaining after extraction of tissue macerates with water[1]. Such residues undoubtedly contain particulate cellular inclusions.

Maize (*Zea mays*) coleoptiles were chosen for the present study because of the information already available regarding coleoptile tissue. The coleoptiles were excised from 5-day-old seedlings of Michigan 350 hybrid maize which had been germinated at 25° C. and 90 per cent relative humidity. 25 gm. of the coleoptile tissue were homogenized (Servall 'Omnimixer') for 10 min. at 16,000 r.p.m. together with 180 ml. of glycerol and 37 gm. of glass beads 200μ in diameter (Minnesota Mining and Manufacturing Company, Saint Paul, Minnesota). The homogenate so obtained was permitted to stand for $\frac{1}{2}$ hr. during which time the bulk of the beads settled out. The supernatant fluid (Fig. 1*A*) was decanted into a 150-ml. coarse-porosity sintered glass funnel containing a filter-bed consisting of 1 cm. of the 200-μ glass beads. Filtration was accomplished at the suction pump with continual stirring at gradually increasing depth in the glass-bead filter so as to prevent mat formation. Plastids, nuclei, mitochondria and soluble protein appeared in the filtrate while the cell walls remained in the glass-bead filter-

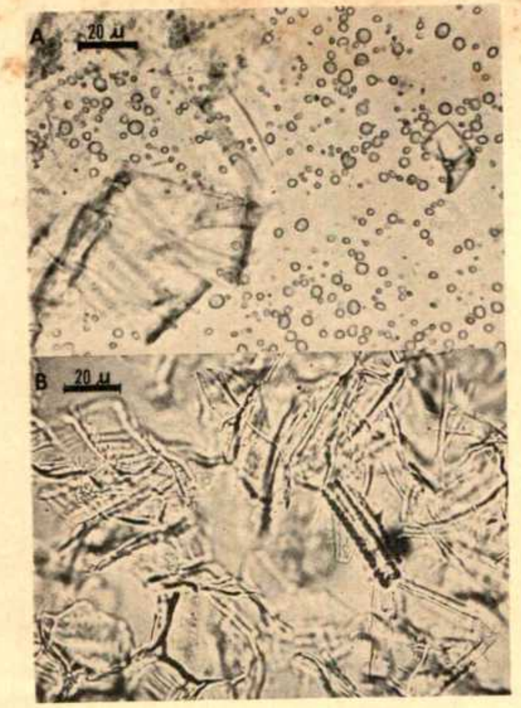

Fig. 1. Photomicrographs of cell-wall preparations at two stages of purification: *A*, crude homogenate showing cell-wall fragments and plastids; *B*, purified cell-wall fragments after fourth filtration

mat. The beads together with cell-wall material were resuspended in 50 ml. of glycerol and the mixture again allowed to settle for ½ hr. The supernatant fluid containing the suspended cell walls was again decanted into a fresh glass-bead funnel and the filtration and settling procedure repeated three times. After the last resuspension, the beads were again allowed to settle and the traces of beads remaining removed by centrifugation for 5 min. at 500*g*. The cell-wall material was then collected as a pellet by centrifugation at 25,000*g* for ½ hr. Purified cell-wall preparations so obtained constitute about 5 per cent of the initial dry weight of the corn coleoptile tissue and are practically free of microscopically visible and histochemically detectable cell inclusions as shown in Fig. 1*B*. If the filtration fluids are reworked until all visible cell-wall fragments have been removed, a yield of 20 per cent of the coleoptile dry weight is obtained. For chemical analysis, the cell-wall material was washed free of glycerol by suspension and resedimentation five times in a ten-fold volume of absolute alcohol and dried to constant weight.

The results of analysis of cell-wall preparations and of whole dried coleoptile tissue are presented and compared with those of other authors in Table 1. To our knowledge, no previous reports of the sulphur, calcium or magnesium contents of primary cell-wall tissue have been published. In general our results are in accord with previously published values with the notable exception of the protein content of the cell walls. Thimann and Bonner reported 12 per cent protein for *Avena* coleoptile (corresponding to 1·9 per cent nitrogen) while Nakamura and Hess reported 30·4 per cent protein for a water-insoluble fraction of maize coleoptile. In the present work, protein, calculated from the nitrogen determinations, would be 2·5–5·1 per cent. Probably the higher values previously reported are due to a greater degree of

Table 1. COMPOSITION OF COLEOPTILE AND CELL-WALL PREPARATIO OF COLEOPTILE OF *Zea* AND *Avena*[*]

	Whole coleoptile (per cent dry weight)	Coleoptile cell-wall (per cent dry weight)

contamination of the cell-wall preparation by cyt plasmic substances.

A limited characterization of the polysacchari components of the cell wall was made by the gene procedure of Norman[2]. Cellulose was extracted fro the 0·5 per cent ammonium oxalate insoluble cell-w fraction with 72 per cent sulphuric acid after hydrol sis with 2 *N* hydrochloric acid. The extract w diluted to 5 per cent sulphuric acid, hydrolysed, a glucose was determined with the aid of gluco oxidase. By this procedure the cellulose content w calculated to be 27 per cent. The 'pectin fractio as isolated by the usual precipitation method fr ammonium oxalate extracts constituted 28 per ce of the dry weight of the cell-wall preparation. Pa chromatographic examination of the 'pectin fracti following exhaustive methylation and acid hydro sis[3] indicated that only 2–5 per cent of the cell-w weight was polyuronic acid. Since losses of uro acid by this method might be expected, the value 8 per cent obtained by Dr. Albersheim seems corre The ribonucleic acid content of the cell wall w found to be less than 0·15 per cent as determined the method of Ogur and Rosen[4]. This would accou for approximately half the total cell-wall phospho

In summary, our present analysis accounts for o approximately 45 per cent of the cell-wall dry weig Qualitatively, it may be stated that starch a dextrines are absent but there are large amounts pentose and hexose polysaccharides. Further stud of these as yet uncharacterized carbohydrate fr tions and the enzymatic activities of cell-wall fr ments are in progress.

This work was supported in part by the Michig Agricultural Experiment Station and by the Natio Science Foundation.

FORTHCOMING EVENTS

Sunday, September 6—Wednesday, September 9

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE (at York) —Continuation of Annual Meeting

Sunday, September 6

At 10 30 a m.—(in York Minster)—Religious Service Preacher The Most Reverend the Lord Archbishop of York

Monday, September 7

At 10 a m —Prof O M B Bulman, F R S "Recent Developnents and Trends in Palæontology" (Presidential Address, Section C)

At 10 a m —Prof Ian A Richmond "The Nature and Scope of Archæology" (Presidential Address, Section H)

At 10 a m —Prof A Hemingway "Artificial Organs—Biological Applications" (Presidential Address, Section I)

At 8 p m —Sir William Hildred "International Air Transport Problems" (Evening Discourse)

Thursday, September 10—Friday, September 11

SOCIETY OF INSTRUMENT TECHNOLOGY (at the Polytechnic, Regent Street, London, W 1), at 9 15 a m Thursday and 10 a m Friday—Education Conference

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or efore the dates mentioned

ASSISTANT LECTURER (with an honours or special degree in psychology or equivalent) IN PSYCHOLOGY—The Secretary, Bedford College University of London), Regent's Park, London, N W 1 (September 4)

LECTURER IN EDUCATION at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British ommonwealth, 36 Gordon Square, London, W C 1 (New Zealand, eptember 20)

LECTURER (with a good honours degree in electrical engineering or hysics, and industrial or research experience in light-current electrical ngineering) IN ELECTRICAL ENGINEERING at Queen's College, Dundee University of St Andrews)—Joint Clerk to the University Court, Queen's College, Dundee (September 28)

ASSISTANT LECTURER IN SOCIAL ADMINISTRATION—The Registrar, The University, Manchester 13 (September 30)

LECTURER IN MATHEMATICS at the University of New England, ustralia—The Secretary, Association of Universities of the British ommonwealth, 36 Gordon Square, London, W C 1 (Australia, eptember 30)

LECTURER IN ZOOLOGY at the University of Queensland, Australia -The Secretary, Association of Universities of the British Commonealth, 36 Gordon Square, London, W C 1 (Australia, September 30)

SENIOR LECTURER IN PHYSICS, a LECTURER IN PHYSICS, and a ECTURER IN SOCIOLOGY at Rhodes University, Grahamstown, South frica—The Secretary, Association of Universities of the British ommonwealth, 36 Gordon Square, London, W C 1 (South Africa, eptember 30)

LECTURER IN GEOGRAPHY at the University of Sydney, Australia—he Secretary, Association of Universities of the British Commonealth, 36 Gordon Square, London, W C 1 (Australia, October 1)

CHAIR OF CHEMISTRY at Bedford College—The Academic Registrar, niversity of London, Senate House, London, W C 1 (October 5)

CHAIR OF PHYSICS in the University of Tasmania—The Secretary, ssociation of Universities of the British Commonwealth, 36 Gordon quare, London, W C 1 (Australia, October 15)

LECTURER or ASSISTANT LECTURER (with special qualifications in hysical chemistry) IN CHEMISTRY—Secretary, The Royal College Science and Technology, Glasgow

MAP CURATOR IN THE DEPARTMENT OF GEOGRAPHY AND GEOLOGY -The Registrar, University College of Wales, Aberystwyth

EDUCATIONAL PROBLEMS OF THE COMMONWEALTH

SEVERAL recent events of great public importance have received little or no public discussion, due resumably to the stoppage in the printing industry n Great Britain Among these events the Commonvealth Education Conference, which met in Oxford uring July 15–29, is outstanding As the Secretary f State for Commonwealth Relations, Lord Home, tated in the House of Lords on July 2, this Conerence was called primarily to work out detailed rrangements for the new scheme for a thousand ommonwealth scholarships and fellowships, which vas agreed upon by Commonwealth Ministers at the Trade and Economic Conference held in Montreal in eptember 1958 The Conference, however, was also o review existing arrangements for co-operation etween the Commonwealth countries on education enerally, and although it was to settle its own genda, Lord Home indicated that the supply and raining of teachers and scientific and technical ducation would be subjects of particular importance

In making this statement, Lord Home expressed he hope that from the Conference there would merge practical schemes for furthering co-operation n this vitally important matter of education, where he needs are so great and where Commonwealth ountries have so much to offer one another Lord ome emphasized, too, the high standing of the ommonwealth representatives at the Conference, of vhich Lord Halifax was president and Sir Philip orris was chairman, and he referred also to the even study tours of the United Kingdom, designed o give the delegates a balanced insight into our resent system and its working, one of which each verseas delegate would make before the Conference pened The contribution of the United Kingdom in ommonwealth education is also described in a booket prepared specially for the Conference by the entral Office of Information (Hercules House, Vestminster Bridge Road, London, S E 1)

The simple fact, to which also Lord Home directed ttention on July 3, that any schemes which the onference might propose would almost inevitably nvolve money, sufficiently indicates the importance f wide and informed public discussion of the whole ubject The magnitude of the contribution which ritain is already making in this field must be fully nderstood, both in Britain and in the Commonvealth, and the implications elsewhere in terms of an-power, even more than in terms of material or nancial resources, if the proposals of the Conference re to be correctly appraised, still more if the resources equired are to be forthcoming There can be few ubjects which better illustrate the bearing of inormed discussion on the functioning of democratic nstitutions, as there are also few in which party olitics could be more damaging or dangerous. ndeed over wide areas, and especially in Africa, he success of self-government and the survival of democratic institutions may largely depend on our success in solving the problems involved in the expansion of education, especially secondary education, and in reconciling the clash between the comparatively slow, healthy growth in educational institutions and the mounting demand for rapid political change

In opening the Conference on July 15, the Earl of Halifax stressed the practical objectives of the Conference, and pointed out that to-day it is a question of the right sort of education at the right time Freedom itself will depend upon the education we are now providing for our young people, both because of the technical skills that education can provide and because of the qualities of character and mind that go with it Lord Home, in a speech on the opening night of the Conference, referred to the importance of the common pattern of education in the Commonwealth and the practical co-operation on which it is based, both in relation to the particular objectives of the Conference itself and in the wider context of the promotion of international understanding, to which the interchange of teachers and students could make a most effective contribution

Speaking in the House of Lords on July 29, Lord Home claimed that the Conference had been an outstanding success In the ten working days at Oxford, plans had been made not only to bring into operation the Commonwealth scholarship scheme approved in principle at Montreal, but also to provide for both short- and long-term assistance to those Commonwealth countries where a shortage of teachers at all levels is holding up the development of education and the progress of the economy The scholarship scheme itself will cost about £5 million during the first five-year period, of which the 500 scholarships provided by the United Kingdom will take about half With the 250 offered by Canada, 100 each by India and Australia, 30 by Pakistan, 25 by New Zealand, 12 each by Malaya and Nigeria, 10 each by Ghana and Rhodesia and Nyasaland, 6 by Ceylon and 4 by East Africa, the target of 1,000 scholarships is already exceeded For the most part the scholarships will be given to graduates for research or work for higher degrees in universities and comparable institutions in other Commonwealth countries than their own, and the scholarships will be tenable for an average period of two years and be comparable in standing with the best offered by any other country or in any other way

A small number of visiting fellowships to enable distinguished Commonwealth professors to visit other Commonwealth countries and to work at institutions of their own choice will supplement the scholarships, and a few scholarships will also be tenable at the undergraduate-level where the courses required by the candidates are not available in their own countries It may be recalled that the United Kingdom has already contributed in grants and loans under the Colonial Development and Welfare Acts some £13 million to higher education, and that there were in 1958–59 more than 7,000 full-time students from other parts of the Commonwealth enrolled in universities of the United Kingdom with some 6,600 students in technical colleges, and of these some 250 were trainees under the Colombo Plan, so that the new scheme is only an extension in scale , and Lord Home pointed out in the House of Lords that the Conference itself recognized that it was only making a start on the most urgent and specific needs It therefore recommended that another Commonwealth Education Conference should meet in 1961 to review progress and to make further plans

Lord Home's statement in the House of Lords showed that the Conference also frankly recognized that the most serious problem is that of teachers, and especially of those qualified to teach in the secondary schools, and that this special need of the emergent countries can only be met by special efforts on the part of the senior members of the Commonwealth The United Kingdom is already sending some 2,500 teachers a year to Commonwealth countries, but the Conference estimated that about a thousand more teachers are wanted each year for secondary schools, and two hundred for technical schools , in addition, 500 are wanted at once for teacher-training colleges

Lord Home said, quite correctly, that in the short run the quickest way is to send out teachers already trained to occupy key posts overseas, and this the older Commonwealth countries are proposing to do University lecturers and professors would be encouraged to take up overseas posts, and in the United Kingdom a special effort will be made to help with teachers in those scientific and engineering subjects in which Commonwealth countries have reported their needs are greatest These subjects are, of course, those where the shortage of teachers is felt acutely in the United Kingdom, and Lord Home commented that, if the objective is to be achieved, administrative measures will be necessary including the topping-up of salaries calculated on the local scale, the provision of passages for the teacher and his family, preservation of his pension rights and promotion prospects and assistance in resettlement on return In promising the Conference that the British Government would help with such measures, Lord Home appealed also to teachers to respond to the challenge presented to men and women of talent, imagination and sympathy

The United Kingdom proposals provide for some four hundred additional United Kingdom teachers to serve in Commonwealth countries, but the long-term solution must be to build up the educational resources of the smaller Commonwealth countries by providing the staffs for new teacher-training institutions which they may decide to establish, either in their own territory or jointly to serve the needs of a particular region Accordingly, said Lord Home, we would provide in the United Kingdom five hundred more places for teacher trainees from those countries as from the academic year 1960–61, and £250,000 a year for grants to the students occupying them There were already, in 1958–59, 728 Commonwealth students training as teachers in the United Kingdom and if, as Lord Home stated, Canada, Australia, New Zealand, India and other countries make considerable contributions, the position should be significantly improved when the next Conference meets

The expansion of technical education will take time, but here also the Conference has initiated new efforts to speed the process The need for trained teachers in technical subjects, the continuing need for industrial training and the great shortage of suitable books and equipment were all emphasized In the United Kingdom, it is planned that during the next ten years some 4,000 additional places will be available to the Commonwealth students in technical colleges The Federation of British Industries and the industrial research associations have already indicated their intention to continue the facilities now offered to overseas students and to expand them in certain directions

These further projects discussed at the Conference are estimated to cost at least a further £5 million during the next five years, of which the United Kingdom contribution will be about £3 5 million, making a contribution of some £6 million out of the total of at least £10 million This, as Lord Home observed, is a substantial contribution, and it does not stand alone Indeed, it is not easy to estimate the full financial magnitude of the United Kingdom contribution to Commonwealth education even at the university-level Account has to be taken of what is being done through the British Council, the Nuffield Foundation and like institutions, and through the Commonwealth University Interchange scheme

Even if the financial magnitude of the British contribution could be accurately assessed, this is possibly the least important aspect Compared with the magnitude of expenditure on education in Britain alone—estimated as likely to exceed £1,000 million within the next decade—it is relatively trivial, and it is small also in comparison with expenditure in Britain on scientific and industrial research, with which it is so closely connected Essential as it is that adequate financial resources should be available for Commonwealth education, man-power is the decisive factor, and it is imperative that financial resources should be wisely applied so as to remove so far as possible all obstacles to the free interchange of students and teachers The benefits of such movement are reciprocal, and the Conference should at least have emphasized that in such wandering scholars the Commonwealth has one of its most valuable assets

On that there are perhaps two points of special interest at the present time Prof Kenneth Robinson has directed attention to the value of extending interchange to research and to the need for research fellowships and studentships which would enable young United Kingdom graduates to spend a year or two in one of the other countries of the Commonwealth, studying some aspect of the history, culture or contemporary social, political or economic problems of that country There are, he claims, many urgent and important pieces of research in this field which young United Kingdom graduates cannot at present be encouraged to undertake because of the lack of opportunity to spend the necessary time in the Commonwealth country concerned Such work is at present often done by Americans, although the Nuffield Foundation has supported some such studies and the Commonwealth universities are fully alive to the value of such Rhodes scholarships in reverse Nevertheless, there is an undoubted need for a rapid extension and increase of funds and facilities enabling United Kingdom graduates to spend substantial periods on research work overseas, and it should not be forgotten that a further beneficial result would be to build up in Britain a growing corps of graduates who would have first-hand knowledge of the problems and culture of other parts of the Commonwealth

The second and even more urgent point is that of the supply of teachers, and especially secondary school teachers Prof Arthur Lewis, when economic adviser to the Ghana Government, estimated that countries emerging from Colonial status are not self-sufficient in secondary school teachers until about 4 per cent of each generation is entering the secondary schools Only in Western Nigeria is this proportion reached, though in Ghana great efforts are being made in the current development plan to exceed the present 2 per cent Many other territories, such as Kenya, Nyasaland and Northern Nigeria, are far behind; and although in some territories the primary school numbers are creditable, until comparatively recently there has been practically no secondary education in many areas.

What the Commonwealth Education Conference has emphasized above all is that advance in education depends not only on sufficient financial resources but still more on foresight, patience and sacrifice Teachers of the calibre demanded for secondary schools, especially for work in the sixth forms, are not to be found overnight Their training calls for tutors of high calibre, and time to complete that training not simply in secondary courses but also n teachers' training courses and sometimes to graduate-level in university institutions

This is the real—and the key—problem in education for the emergent territories, and it is only indirectly and in the long term that the scholarship scheme at the university-level will contribute to its solution Meanwhile, the emergent territories depend on the older members of the Commonwealth for the help essential to build up as rapidly as possible ystems of secondary education capable of meeting he demands for emergent nationhood Financially, his is bound to involve expenditure far in excess of the £10 million immediately contemplated at the Commonwealth Education Conference, including apital expenditure as well as grants for recurrent xpenditure on secondary education, while an even greater strain may be put on the human resources f the Commonwealth

Of this Lord Home was manifestly conscious in his appeal, at the closing of the Conference, so far as higher education is concerned, and it is no less true of secondary education Most of the senior members of the Commonwealth are themselves short of secondary school teachers—in some the shortage is a result of the racial policies pursued by them—and special measures are already being concerted in the United Kingdom to meet the situation arising as 'the bulge' approaches our sixth forms The measures promised by Lord Home may help to increase the numbers of teachers which we already send to Commonwealth countries, though it may still be necessary to explore other possible emergency measures which changes in our economy may offer These alone will not suffice, however, without the imaginative response and enthusiasm for which Lord Home appealed To create the public and professional understanding on which such a response can be soundly based is an urgent and primary task for which the Government has a primary responsibility For this reason it is imperative to expedite as much as possible the publication of the full report of the Conference, and ensure that it is widely discussed both in Parliament and outside

BERTRAND RUSSELL, PHILOSOPHER

My Philosophical Development

By Bertrand Russell Pp 279 (London George Allen and Unwin, Ltd, 1959) 18*s* net

ALL those whose study of philosophy is grounded in the empirical tradition regard Lord Russell as the greatest living philosopher His philosophizing started in the 'nineties when philosophy in Britain, in Europe and most of the United States was dominated by idealisms deriving either from Hegel or from Kant After a few years as a "full-fledged Hegelian" (p 42), Russell tells us that in 1898 both G E Moore and he "rebelled against both Kant and Hegel" (p 54) From this rebellion sprang the current of empiricist or 'scientific' or 'analytic' philosophy which to-day, in one form or another, dominates philosophical thinking and teaching throughout the English-speaking world and plays an important part in the pattern of our contemporary culture Although one should not neglect other influences—in particular, that of Moore, of Frege, of the Polish philosophers, of C S Peirce and the American pragmatists, and of the greatest of Russell's pupils Wittgenstein (about whom there is a good deal in this book)—there is no doubt that the main responsibility for the present state of philosophy lies squarely on Russell's shoulders Without his work in the first quarter of this century it is difficult to see how the logical positivist movement could have arisen, and, if philosophers' interest in the use of language had developed independently of analytic philosophy, it would have taken a much less realist form Russell's influence has been largely due to his immense fertility of ideas, and to his willingness to publish them even though he might later have to retract or modify his conclusions There are few philosophers in history who have written important philosophical works almost continuously for fifty years Russell has added to the immense debt we owe him by now giving us a full-scale account of his philosophical development, written with all the clarity, verve and wit we are accustomed to expect from anything he writes

"My philosophical development," Russell starts the book by saying, "may be divided into various stages according to the problems with which I have been concerned and the men whose work has influenced me There is only one constant preoccupation I have throughout been anxious to discover how much we can be said to know and with what degree of certainty or doubtfulness" (p 11) Considering rational bases for geometry and for mechanics led Russell back to arithmetic , and four chapters of this book are devoted to general questions involved in his attempt to derive mathematics from logic, which culminated in Whitehead and Russell's "Principia Mathematica" Russell gives a lucid informal account of the logical paradoxes which caused him so much trouble, and of the theory of types which he invented in 1908 to solve them Though systems of mathematical logic have been constructed recently which do not explicitly make use of distinctions of type in Russell's manner, they almost all presuppose restrictions upon the use of symbols which are virtually equivalent to a type theory The philosophical insight in Russell's theory is that a sentence may be perfectly well constructed according to grammatical rules and yet lack meaning there are logical restrictions upon the significant combination of symbols as well as purely grammatical ones The emphasis later laid by logical positivists upon the nonsensicality of many apparently sensible expressions was foreshadowed in Russell's theory of types (see pp 14, 160)

After 1910 Russell turned his attention to theory of knowledge, and in 1914 put forward his well-known programme of substituting, so far as possible, logical constructions for inferred entities This programme, and the similar 'operationalist' programme advanced by P W Bridgman in 1927, has made great appeal to philosophers of science, many of whom have attempted to apply it to the construction of various scientific concepts In this book Russell says that he "soon became persuaded that this is an impossible programme and that physical objects cannot be interpreted as structures composed of elements actually experienced" (p 105) I do not think that Russell ever published his reasons for his change of view cogent reasons for the impossibility of the logical construction programme were first given by F P Ramsey in 1931 In Russell's later writings, and in this book, similarity of structure is taken as being the connecting link between the electromagnetic waves used in broadcasting and auditory sensations (p 204) Though Russell speaks (not very happily, I think) of scientific knowledge using "artificially manufactured entities", "real or supposed entities", "scientific abstractions" (pp 205–6), "constructions composed of events and taken as units for the convenience of the mathematician" (p 27), he would not now regard these as having to be given, directly or indirectly, in terms of experience "I cannot see that there is any ground whatever for this opinion [that there can be nothing which is not experienced or experience], nor even for the view that we cannot know that there are things we do not know" (p 144)

Other problems with which Russell has been concerned and which he treats in this book are those of consciousness and perception, of non-demonstrative inference, of truth, of names and of language i general With regard to language, Russell recount how he moved from regarding it as "transparent" t realizing its philosophical importance Nevertheles "the essential thing about language is that it ha meaning—i e , that it is related to something othe than itself, which is, in general, non-linguistic" (p 14) "In regard to truth and falsehood, a sentence is onl important as a vehicle of belief" (p 154) Russel wholly rejects the view that the study of language i an end in itself for a philosopher Nor does he accep any hard and fast separation of philosophy fro science "Philosophy cannot be fruitful if divorce from empirical science" (p 254) Of the outcome o his recent work on inference he says that "the reason for accepting it are the ordinary reasons applied i scientific work, not remote reasons derived from som metaphysical theory There is no claim to certainty" (p 207) In this book Russell does not (as h did in 1914) speak of "scientific method in philosophy", a phrase which may mean anything o nothing But if by the scientific spirit is meant th persistent and single-minded attempt to "understan the world" (p 230) by envisaging bold but tentativ hypotheses without ever losing sight of the facts whic these hypotheses are intended to explain, Russell' work exemplifies this spirit better than does that c any other contemporary philosopher

R B BRAITHWAITE

CATALYSIS

Catalysis

Edited by Paul H Emmett Vol. 5 Hydrogenatio Oxo-Synthesis, Hydrocracking, Hydrodesulphurization, Hydrogen Isotope Exchange and Relate Catalytic Reactions Pp vi+542 (New York Reinhold Publishing Corporation , London Chapman and Hall, Ltd , 1957) 120*s*

Advances in Catalysis and Related Subjects

Edited by Adalbert Farkas Vol 9. Pp xviii+847 (New York Academic Press Inc , London Academic Books, Ltd , 1957) 16 dollars

VOLUME 5 of "Catalysis" continues the description of various hydrogenation processes whic has already extended through the previous tw volumes , and the allotment of so much space, eve in a major treatise on catalysis, is in itself a sig of the importance which this type of reaction ha attained in modern academic and industrial chemistr Following an introductory section on the gener reactivity of carbon monoxide, I Wender, H W Sternberg and M Orchin contribute a well-writte chapter on the high-pressure hydrogenation of mixtures of carbon monoxide and olefines to long-cha ketones by the oxo reaction. In this, considerabl interest is attached to the use of soluble catalyst derived from cobalt or nickel carbonyls since, in th way, homogeneous liquid hydrogenation systems ca be obtained A good survey is also given of th general theory of the reaction mechanism involved an of the part played by carbonium ions in this Th next chapter, by G Natta, U Colombo and I Pasquon, deals with the use of promoted mixed-oxid catalysts for the hydrogenation of carbon monoxid to higher aliphatic alcohols and supplements a sectio in an earlier volume on the synthesis of methyl alcoho There is, in this field, abundant scope for the furthe study of the basic mechanism of promoter actio about which relatively little is known in spite of the very large amount of work which has been done on the subject

The long monograph on the hydrogenation of aromatic compounds by H A Smith, who has himself contributed considerably to our knowledge of this subject, stands out as a comprehensive survey and reviews systematically a very large number of papers covering the catalytic reduction of carbocyclic and heterocyclic substances This detailed treatment also occurs in the chapter by T I Taylor on the use of hydrogen isotopes for the detection of subsidiary processes involving hydrogen exchange, bond migration or other reactions which are superimposed on the ydrogenation itself and, in many cases, cannot easily be recognized in other ways In addition, the method throws considerable light on the internal complexity of hydrogenation generally Finally, the article by J B McKinley on the hydrodesulphurization of liquid petroleum fractions gives an authoritative survey of a type of process which has done much to mprove the general quality of commercial motor spirit and which has only become practicable economically by the recent availability of very large quantities of by-product hydrogen derived from ydroforming reactions

In a major work of this type, published with rather long intervals of time between the issue of the individual volumes, it is difficult to avoid some ack of logical sequence for example, the wide separation of the article on the synthesis of higher alcohols in the present volume from that of methyl alcohol in Volume 3, and the chapter on the hydrogenation of aromatic compounds from those on the eduction of olefines and acetylenic derivatives This, however, is a minor criticism , and the work as a whole is to be recommended as an up-to-date treatise on catalysis, which should be of great value to the many chemists who are interested in this subject

The publication, as a volume of "Advances in Catalysis", of the 84 papers which were read at the nternational congress on catalysis held in Philaelphia in 1956 constitutes an alternative policy to he spreading of these contributions in a single and apidly growing field of knowledge among a relatively rge number of individual journals, some of which ay be accessible only with difficulty to chemists orking in smaller institutions In addition, it orms one way of relieving the increasing pressure hich is being felt by some of the various publishing ocieties in providing adequate space for the accomodation of all the otherwise suitable papers now sent n to them

Following introductory addresses by Sir Hugh aylor and by Sir Eric Rideal on general aspects of talysis and on the course of its development from a storical point of view, the large mass of new material s been arranged in four main groups covering espectively the chemistry and physics of solid talysts, homogeneous catalysis, surface chemistry enerally, and miscellaneous catalytic reactions, any of these groups being subdivided into subections While it is difficult in a short review to elect individual papers for special comment, conderable interest is attached in the first of these oups to the contribution by R E Cunningham and T Gwathmey on the relative rates of hydrogenaon of ethylene on the various crystal planes which e exposed as outcrops on the surface of a spherical ngle nickel crystal The relative rates observed uld not be explained in terms of the ease of geometrical accommodation, without undue strain, of the ethylene molecule , and it is probable that bulk dislocations, which begin within the catalyst, lead to unusual interatomic distances in the surface lattice Prof J H de Boer amplifies this point by discussing the part played by pore structure in providing sites for reaction within the gross external surface of supported and other catalysts

In a further introductory address, Prof W E. Garner gives a good account of the present state of work on reactions involving electron transfer on and in mixed-oxide catalysts, including semiconductors , and this is supplemented by a number of further papers in this field, including one by Prof G M. Schwab in which the effect of illumination on electron-transfer processes between the surface of semiconductors and catalysable substrates is discussed. Reaction paths and energy barriers in homogeneous catalytic systems have been dealt with by Prof D D. Eley, who also includes processes catalysed by enzymes Later sub-sections contain a large number of papers on the relation of surface chemistry to catalysis, the catalytic reactions of hydrocarbons (which is introduced by Dr E J Houdry), tracer techniques, with an introduction by Prof P H. Emmett, and miscellaneous catalytic reactions The subsequent discussions to all the papers are printed in full

E B Maxted

INTRODUCTORY ELECTRONICS

Principles of Electronics

By Prof M R Gavin and Dr J E Houldin (Physical Science Texts) Pp xii + 348 (London English Universities Press, Ltd , 1959) 30s net

THE trouble with this book is that it is not really clear for whom it is written The general editor's foreword states that each volume in the series "is designed to give the reader an integrated account of a subject up to the level of an Honours Degree of any British or Commonwealth University" But the authors claim that it is only a general introduction to the subject of electronics or, as shown on the dust cover, "an introductory course for a first degree or diploma in physics or electrical engineering" , then they go on to claim that, for most of the book, the standard of mathematics required is no more than that of the Advanced Level of the General Certificate of Education Whatever the intentions, there is little doubt that the book is very suitable for the early years of an electrical engineering course but will scarcely cover the requirements of the final stages of an honours course in electrical engineering

Within the restrictions mentioned above, the book is a good one Its descriptions are extraordinarily lucid and straightforward—almost anyone could understand them , and the book might be useful even to technicians It is a book one can enjoy reading , the subject-matter is well selected and strikes a pleasant balance between thermionic valves on one hand and transistors on the other , between physics on one hand and circuits on the other. The coverage of the subject-matter is wide, including the basic electron physics (nearly 100 pages), amplifiers (about 90 pages), oscillators (sinusoidal and relaxation), very-high-frequency valves, rectification, modulation and detection, wave-shaping, and noise It is not surprising that the authors do not find room for communication and control systems or for any study of passive circuits The book is not at any stage abstruse, and unimportant and irrelevant matter seems absent A very valuable feature is the inclusion of about 250 examination-type problems The production is very attractive and the price is reasonable

Not only can the book be recommended as an introductory text for electrical engineering students, but it may also prove useful to many fully fledged engineers and physicists who wish to get up to date on the proper relationship of thermionic and transistor circuits It compares favourably with other recent books on this subject

One or two faults in the book should be mentioned The reviewer did not take kindly to the split infinitives on p 28—"to just ionise" and "to just excite"—nor to the spelling "alinement" on p 37 There is an error in the analysis of a circuit on p 242 (and another similar one on pp 251–2) where the authors neglect the existence of the voltage across the load of a diode D G TUCKER

HISTOLOGY

Textbook of Comparative Histology

By Dr Warren Andrew Pp xix+652 (London and New York Oxford University Press, 1959) 120*s* net

Histochemical Technique

By Dr W G Bruce Casselman (Methuen's Monographs on Biological Subjects) Pp 205 (London Methuen and Co , Ltd , New York John Wiley and Sons, Inc , 1959) 18*s* net

A SURVEY of the histology of both invertebrates and vertebrates in a single volume is indeed a formidable task, and even partial success must rank as a considerable achievement Certainly a cursory examination of Andrew's book does throw its deficiencies into some relief, and more continuous reading is required to reveal its virtues The temptation of saying too little about too much is not entirely avoided and rather many topics are treated too briefly to be easily intelligible, nor is the difficulty overcome of being reasonably up to date, for references from the last decade are somewhat infrequent The chapter bibliographies are unduly short, for the excretory organs of all invertebrates there are thirteen titles ending at 1940, and in general they refer mainly to American and older German work , there is little attempt either to include all the great classical papers or to present a scheme for further reading The coverage of the subject is often correspondingly restricted and there are some disappointing omissions Nevertheless the advanced undergraduate audience for whom the book is primarily intended will find in it much pleasant ancillary reading, arranged in a manner which should stimulate their further interest The broad comparative and essentially functional approach emphasizes the general similarities of the problems facing all animals, and brings out underlying analogies in their solutions The illustrations are numerous and well chosen and the writer's style agreeable, so that such a volume might well lead a student towards one of the most attractive entries into the practice of zoology

The scope and precision of classical histology have been rapidly extended in recent years by the increasing use of physical and chemical methods, and any further assistance in their technical application is welcome Casselman opens with some interesting chapters on the general methods, potentialities and limitations of microscopical histochemistry, followed by succinct accounts of the main groups of substance studied by these techniques The chapter on lipid and their separation, at least to the degree of separation so far feasible, is particularly helpful, but tha on proteins does seem to under-estimate some of th technical difficulties involved The point of viev throughout is chemical and the book can be recommended to biologists primarily as a very useful addition to the other texts now available T KERR

GENETIC ANALYSIS

Trends in Genetic Analysis

By Prof G Pontecorvo (Columbia Biologica Series, No 18) Pp x+145 (New York Columbi University Press , London Oxford Universit Press, 1959) 25*s* net

THE past fifteen years have seen a revolution i genetics comparable to the introduction int physics of quantum theory Several lines of researc have contributed to this revolution The study c biochemical genetics established the concept of 'on gene, one enzyme' The analysis of transformatio and transduction in bacteria showed that hereditar information is carried by nucleic acid These tw conclusions made clear the need to analyse the structure of nucleic acids, to relate this structure to th processes of replication and of protein synthesis, an to seek for the kinds of changes in proteins whic result from genetic mutation But most important c all has been the increase in what Prof Pontecorv has called the "resolving power" of genetic analysi This has caused the abandonment of the old pictur of chromosomes consisting of a series of hereditar units or genes connected by regions at which, an only at which, recombination can take place, and th recognition that genes themselves have a linear structure resolvable by crossing over

Prof Pontecorvo's book is mainly concerned wit this last field of research, although conclusions fro other fields are mentioned where they are relevan The six chapters deal with genetic analysis and i resolving power, allelism, the structure and functio of the genetic material, recombination, mappin chromosomes via mitotic recombination and nov genetic systems

This is an exciting book, partly for the logic an clarity with which new ideas are presented, and partl because the problems which it raises are as fascina ing as the ones which it answers Prof Pontecorv has himself made a decisive contribution to the stud of the fine structure of genes by his recognition an subsequent demonstration that the phenomenon c "position pseudo-allelism" described by E B Lew is not a genetic anomaly, comparable, for exampl to the Notch deficiency in *Drosophila*, but is a typic effect, to be expected if the genetic material is line in its fine structure as well as in its gross morpholog and if its proper functioning depends on the integri of functional units, which Benzer has since pe suaded us to call cistrons For the general biologi who wants to know how this idea has been develope and how it has been combined with discoveries other fields to give a coherent picture of what gen are and what they do, this book is an admirab although sometimes a difficult guide

But the book is mainly intended for geneticist and it seems unlikely that many will be so unwise to leave it unread For them, Prof Pontecorvo greatest virtue is his gift for throwing into relief wh ve do not know The search is already on for the eneticist's Rosetta Stone, that is, for a protein hich can be analysed in the same detail as hæmolobin, determined by a gene the fine structure of hich can be resolved in the same detail as Benzer has esolved the *rII* locus in phage *T*4 But there are ther problems to which no answer is at present in ight One is the relationship between the structure f deoxyribonucleic acid, and the processes of hromosome replication and recombination , it is ot clear at present whether replication and recomination are separate processes or different aspects of he same event A still more fundamental difficulty s the relationship between gene action and morphoenesis If the revolution in genetics achieves its resent objectives, we shall know how a fertilized gg receives the instructions which tell it how to ake a large number of specific proteins , but there s a big difference between a bag of proteins and an nimal or plant J MAYNARD SMITH

NEW APPROACH TO IMMUNITY

he Clonal Selection Theory of Acquired Immunity

y Sir Macfarlane Burnet (The Abraham Flexner
ectures of Vanderbilt University, 1958) Pp
x+209 (Cambridge At the University Press ,
ashville, Tennessee Vanderbilt University Press,
959) 22*s* 6*d* net

THE basic problem of immunology is to understand how the body responds by making antibodies gainst foreign macromolecules, while refraining from aking antibodies against the great variety of macroolecules which are present in its own tissues No atisfactory instructive theory has been yet put orward to explain how the presence of the antigen auses cells to synthesize antibody molecules with a omplementary surface structure In the Abraham lexner Lectures given at Vanderbilt University for 958, and published in this book, Sir Macfarlane urnet has approached the problem at quite a ifferent angle He postulates that individual esenchymal cells are genetically endowed with the otentiality for making globulin capable of combining ith a particular antigenic configuration In the dult organism, contact of the mesenchymal cell with e right antigen causes that cell to proliferate and o differentiate, so as to produce a clone of cells aking, or capable of making, antibody which ombines with the antigen The mesenchymal cells re regarded as being subject to a high rate of somatic utation, so that, when a clone proliferates, some embers will produce globulin better adapted to the ntigen, and these cells in turn will be stimulated electively to proliferate, and so on In this way, ore and more cells will produce antibody capable f combining with more of, or more firmly with, the ntigen surface The problem of antibody production n response to an antigenic stimulus becomes thereore a problem in cell population dynamics, and the ften amazing specificity of antibody for the antigen achieved by a selective, rather than by an instrucve, process To account for the phenomenon of nmunological tolerance, and the failure of antibodies o be formed against molecules present in the organm at birth, Burnet suggests that, during the stage f immunological immaturity, contact of antigen ith cells potentially capable of making antibody gainst it results not in stimulation but in deletion f those clones Hence the adult animal possesses cells capable only of being stimulated by molecules with surface configurations not shared by its own components All other clones become forbidden

If this ingenious theory is correct—in essence, even if not in detail—a fairly ready explanation is available not only for many of the cardinal features of immune responses, such as the difference between primary and secondary, or immunological memory and anamnestic reactions, but also for the development of auto-antibodies According to the clonal solution hypothesis auto-antibodies could be evoked by body constituents which were screened from mesenchymal cells during the stage of immunological immaturity (for example, lens protein, or thyroglobulin), or which only developed later (for example, spermatozoa) They might also arise by somatic mutation in adult life of clones of cells capable of responding to forbidden patterns, such as to nucleic acid Burnet makes the good point that antibodies are normally never formed against even heterologous deoxyribonucleic acid, but that when for some unknown reason they do appear, in persons with disseminated lupus erythematosus, they react with deoxyribonucleic acid from all sources including the nuclei of the sufferer's own cells On the basis of his theory clones capable of making antibody against any deoxyribonucleic acid are forbidden, and eliminated, for the very reason that when antibody *is* formed, as a rare result of a somatic mutation, it will be an auto-antibody

This example illustrates the self-consistency and the attractiveness of the theory It is important to remember, however, that there is very little direct evidence to support its main assumption that clones of mesenchymal cells have a built-in response to a particular antigenic pattern, or to explain their deletion during embryonic life and stimulation later The subsidiary hypothesis that lymphocytes, macrophages, plasma cells and primitive reticulum cells are all interconvertible is one the truth of which is convenient rather than proved, and so is the assumption that mesenchymal cells are hypermutable as regards somatic mutations Biochemically minded readers may be disappointed by the frank rejection of a biochemical approach, and by the relegation to chance variations in a basic globulin structure of the problem of how antibody is synthesized with a pattern complementary to the antigen Some may even be stimulated to try to show that a single cell can produce two or more unrelated antibodies at the same time—a finding which would be difficult to accommodate into the theory, and on which the evidence is at present conflicting

The later chapters set out to show how the theory would apply to a wide range of phenomena from collagen disease to cancer, and to some of the latest experimental findings in immunology Burnet manages with elegance in some cases, ingenuity in others, and occasionally a good deal of stretching to accommodate them all—including at least two experimental findings which have since become highly suspect or been withdrawn This last is mentioned no more than as a warning that Sir Macfarlane has such enthusiasm and confidence in his latest ideas, that he can sweep up everything, including the readers, in his path The ideas are, in any event, original and stimulating and have been carried further than anyone has tried to carry any of the alternative hypotheses It is likely that a good deal of future work will be influenced by them, for their author has a reputation of having hit the right nail on the head on notable occasions in the past J H HUMPHREY

Statistics of Extremes

By Prof E J Gumbel Pp xx+375 (New York Columbia University Press, London Oxford University Press, 1958) 120*s* net

THE theory of extreme values is concerned with the probability distribution of the largest values encountered in samples of finite size it has many applications including the occurrence of floods and droughts and the breakdown of materials, such as aircraft components, subject to varying stresses and strains

Prof Gumbel has for many years been a leading authority on the subject and his book is likely to become a standard work Although the book appears to contain little essentially new theory, it collects and elaborates previous work hitherto widely scattered in the statistical literature and contains many tables and graphs of functions occurring in the theory There is an excellent bibliography containing references to both theoretical and applied work The text includes numerous exercises for the reader The eight chapter headings are "Aims and Tools", "Order Statistics and Their Exceedances", "Exact Distribution of Extremes", "Analytical Study of Extremes", "The First Asymptotic Distribution", "Uses of the First Asymptote", "The Second and Third Asymptotes" and "The Range"

Although several examples of applications are discussed, this book is not a 'cook-book' of practical methods, but it should prove extremely useful to the statistician required to analyse extreme-value data The scientist interested in practical applications will need considerable mathematical and statistical experience to follow the rather concentrated and sophisticated mathematics In particular he may find difficulty in assessing the practical importance of some of the concepts defined and some of the results derived

The high cost probably makes this book one for the library rather than for the individual and is presumably due to the large number of graphs it contains

The Chemistry of Natural Products

Vol 1 The Alkaloids By K W Bentley Pp vii+237 4 dollars Vol. 2 Mono- and Sesquiterpenoids By P de Mayo Pp vii+320 52*s* Vol 3 The Higher Terpenoids By P de Mayo Pp vii+239 42*s* (New York Interscience Publishers, Inc , London Interscience Publishers, Ltd , 1959)

BOOKS on natural products have in the past usually suffered from several disadvantages they have tended to consist of catalogues, and quite frequently have been written by specialists who had rather lost contact with the general body of advancing science and did not emphasize relations to chemistry in general A very welcome tendency is for young and enthusiastic men, themselves deeply involved in the subject from the research side, to summarize fields of research in what might be described as super Ph D theses The advantage of their approach is that it is fresh, but nevertheless authoritative, and that their acquaintance with modern theories of reaction mechanisms and biosynthetic theories enables them to produce monographs which are of general interest and general importance The three books in the title are in this class They should interest and inform advanced undergraduates, research students and university or college teachers who have not had the time to keep up with the literature They are not perhaps exhaustive enough for research specialist but should provide useful starting-points for research The general resemblance to theses, particularly i the formulae, will not please lovers of beautifu books, but presumably they would otherwise hav been more expensive They can be heartily recommended to all who are interested in rapidly advancin fields whether as teachers, students or researc workers

The Psychology of Social Class

By Maurice Halbwachs Translated by Claire Delavenay (Heinemann Books on Sociology) Pp xvii+142 (London William Heinemann, Ltd 1958) 16*s* net

MAURICE HALBWACHS was a French sociologist who learnt in his early manhood to shar the liberalism and democratic principles whic deeply influenced the generation destroyed by th First World War It was his inheritance of thes principles which led to his own death in Buchenwal in 1945, and it is for this that he must be remembere and honoured His work as a sociologist is typical o a transitional age, and his writings on the sociolog of class distinctions and behaviour are of interest i so far as they illustrate the swing-over from the over systematic thinking of the sociologists of the nineteenth century to the empiricism which appears t be gaining ground in the second half of the twentieth

It is evident, however, that Halbwachs had no shaken off his attachment to abstract theories eve as late as 1938, when he wrote this book ; moreove it is also evident that he had not mastered the difficulties of basing generalizations on evidence in suc a way that a framework of truly scientific theor might be constructed On one hand, Halbwach was unable to resist the temptation to quote from th works of the great classical philosophers, as well a the theorists of his own age, such as Durkheim an Weber On the other, he was only too ready to present a mass of often undigested information derive from such sources as the German Government' survey of working-class budgets, carried out i 1927–28 What was lacking in his work was a seriou attempt to relate the evidence to the generalization founded on it

Toward a Systematic Pragmatics

By R M Martin (Studies in Logic and the Foundations of Mathematics) Pp xv+107 (Amsterdam North-Holland Publishing Company, 1959) 24*s*

THIS recent addition to "Studies and Foundations" is a valuable monograph in a highl specialist field, and adds lustre to that distinguishe series The main discussion concerns type-theoretica systems, pragmatical meta-language, analytic trut and absolute intensions These subjects are introduced by a preliminary chapter on the nature o pragmatics In brief, language-systems can be eithe syntactical, semantical or pragmatical, and this corresponds to the order of abstraction

Thus, in syntax, it is only the signs or expression (and their inter-relations) which are interesting I semantics, the objects which the signs denote com into the picture Finally, in pragmatics, the speaker or users of the language are involved The author' point of view is wholly extensional, whereas that o Carnap is intensional The power of extensiona meta-languages to cover a large part of mathematics physics, and even biology, is clearly advantageous

STRONTIUM-90 IN THE AUSTRALIAN ENVIRONMENT, 1957—58

By Dr. F. J. BRYANT
Atomic Energy Research Establishment, Harwell

AND

L. J. DWYER, Dr. J. H. MARTIN and Prof. E. W. TITTERTON, C.M.G.
Australian Atomic Weapons Tests Safety Committee

Introduction

DURING the past four or five years a considerable effort has been made, notably in the United States and the United Kingdom, to gain precise information on the world-wide distribution of radioactive fallout from nuclear weapon tests. Results of such measurements to about mid-1957 were included in the extensive review of the subject prepared by the U.N. Scientific Committee in August 1958[1]. Further results for 1957 and also for 1958 for the United States, the United Kingdom and other areas have since been published, notably by Bryant *et al.*[2-4], Stewart *et al.*[5] and the U.S. Atomic Energy Commission Health and Safety Laboratory[6-9].

In April 1957 the programme of fallout measurements, initiated by the Australian Atomic Weapons Tests Safety Committee[10-15] to cover local weapon tests and to monitor global fallout, was extended to include the determination of strontium-90 in representative Australian materials. Arrangements were made for the sampling of soil, powdered milk, cabbages and human and sheep bone tissue. All samples were sent to the United Kingdom for radiochemical analysis by the Atomic Energy Research Establishment Group at Woolwich Arsenal, under the direction of one of the authors (F. J. B.). In this report results are presented for the early part of the programme extending from May 1957 to September 1958, during which period 243 samples were processed. In order to minimize the radiochemical effort, a number of the bone samples were bulked and the actual chemical analyses were reduced in this way to 148.

Sampling Programme

It is well known that strontium-90 in global fallout enters the human body mainly as a contaminant of dietary materials; the uptake through inhalation is very small by comparison[16]. Therefore, the sampling programme was designed to monitor levels of strontium-90 in materials which are representative of the phases between deposition of strontium-90 on the ground and its absorption into human bone. The primary material of the programme was human bone tissue. Because milk products, generally, are a major contributor of calcium and strontium-90 to the Australian diet, milk was chosen as the important representative dietary material and, for convenience, samples of powdered milk were taken for analysis; however, cabbages were included to monitor the contribution to the diet made by leaf crops. Soil and yearling sheep bone tissue were assayed to provide information on the accumulation and rate of deposition of strontium-90 at ground-level; measurements were also made on total precipitation collected in stainless steel pots during the latter half of 1958.

The materials selected, and the sampling procedures adopted, were not expected to allow a complete examination of the uptake processes. This can most satisfactorily be done by controlled experimentation within a laboratory, of the type carried out by Russell and his Agricultural Research Council group[17-19].

Samples of human bone tissue, powdered milk, cabbages and soil were taken from the Perth, Adelaide, Melbourne, Sydney and Brisbane areas during 1957 and 1958, while sheep bones were

supplied from 23 localities throughout Australia during the same period , these materials were taken from sites across the continent within a range of latitudes of 20°–38° S The analytical methods used for the determination of strontium-90 were those described by Bryant *et al* [2,3 16,20]

Sampling Methods and Results

The results are given in Tables 1–5 and wherever possible mean values and the corresponding errors have been derived to facilitate comparisons with the results of similar surveys conducted elsewhere

(*a*) *Human Bone Tissue* Between December 1957 and September 1958 pathologists in the five capital cities supplied a total of 142 specimens of human bone tissue For each area the specimens were divided into three age-groups, namely, under 5 years, 5–20 years and over 20 years In the latter two groups some bulking of material was employed to reduce the number of analyses, while the majority of the infant specimens were analysed individually In all, 47 analyses were performed

It was impracticable to restrict the survey to a single type of bone, and samples of vertebræ, femora and crania were accepted , when adult femora were supplied only the shafts were analysed, but whole bones were included for the younger specimens Each specimen comprised at least 20 gm of wet bone

For each age-group and area the various bone types were not mixed in the bulking of material prior to analysis Information could, therefore, be obtained on any variations of strontium-90 concentration among the bone types employed Because the proportion of calcium in bone ash is approximately constant[21], the bulking of specimens was performed on the basis of equal masses of ash

The final stage of the radiochemical analysis took one of two courses depending on the activity of the

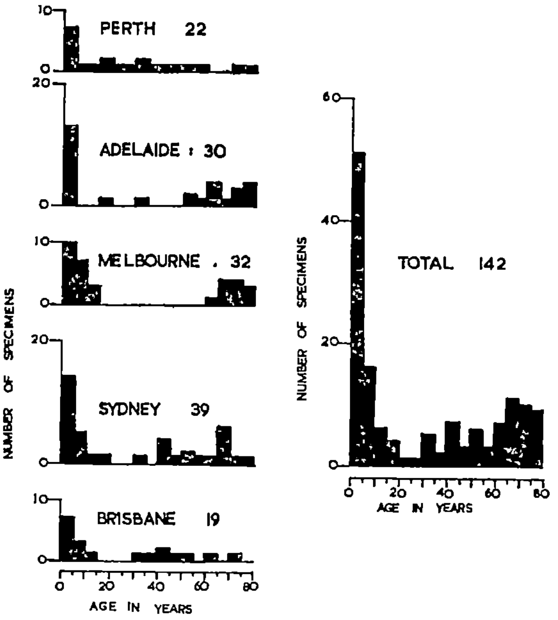

Fig 1 Age distribution of the human bone specimens

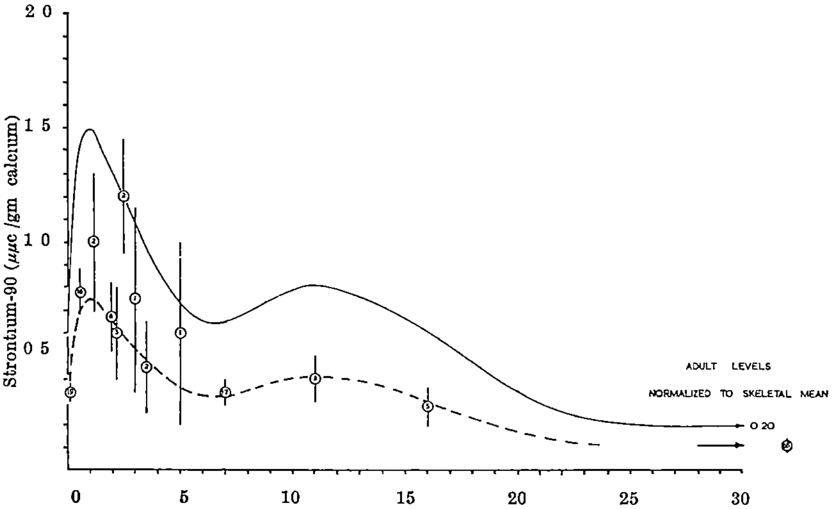

Fig 2 Variation with age of strontium-90 concentration in human bone tissue O, Australia, May 1958 , ——, North America and Europe, January 1958 (ref 23), – – –, 0 5 (North America and Europe, January 1958)

extracted strontium isotopes, strontium-89 and -90 Where possible yttrium-90 was separated for counting after equilibration with mother strontium-90 , on the other hand, for low activities the unwanted strontium-89 was allowed to decay for about two half-lives and the strontium-90 content estimated Both methods gave consistent results

Fig 1 shows the age distribution of the specimens collected, from which it will be seen that the unequal availability of material, particularly in the middle years, has led to emphasis on very young and old tissue The complete data are recorded in Tables 1*a*, *b* and *c* and the distribution of strontium-90 concentration with age is exhibited in Fig 2 The mean values derived in the tables, and also those plotted in Fig 2, are considered to refer to strontium-90-levels in human bone at May 1958

Table 1*c* shows that there is no evidence for a bone variation in age-groups up to 20 years , however, for older tissue, vertebræ have a considerably higher contamination than femora, as reported by the Lamont Group[22–24], from more extensive measurements The results for adults, therefore, have been normalized to the skeletal mean using the factors derived by Schulert *et al* [22]

No significant variations of strontium-90 in human bone were observed between the five capital cities, and so the five groups of data were combined to give the mean strontium-90 concentrations in age-groups, plotted in Fig 2 The estimated standard deviations and the number of specimens on which the mean values were based are also shown A distribution of strontium-90 concentration with age, computed by Kulp *et al* [23], gives a good description of their North American and European bone tissue data of January 1958 This distribution is shown as the full curve in Fig 2, while, as the broken curve, it has been scaled down by 2 to facilitate comparison with Australian data of May 1958

* Each sample was at least 1 5 kgm † Taken in January 1958
‡ Rainfall periods taken to and from January 1958

(*b*) *Milk* The powdered milk samples were taken from factories supplying the five capital cities in August 1957 and March and August 1958 In each case the milk was of known age and origin and the later samples were taken from cattle grazing in the same locality, although not necessarily the same pasture All but a few samples were full-cream powdered milk

The analytical results are given in Table 2 and show the March 1958 levels to be lower than those for August 1957 and 1958, suggesting a seasonal variation of the type noted by other authors, for example, Stewart *et al* [5,25]

(*c*) *Cabbages* During August 1957 and 1958, two or three cabbages grown within the vicinity of each of the five capital cities were ashed for analysis without prior washing or other preparation Before the determination of both calcium and strontium-90 contents the ash from each sample was decomposed with a mixture of HF and $HClO_4$ in the presence of strontium and barium carriers The analytical results are presented in Table 3

(*d*) *Sheep Bone Tissue* This material was included in the programme because the strontium-90 accumulation in the bones of yearling sheep can be used as a monitor of fallout deposition Moreover, through their habit of grazing extensively, sheep

tend to integrate out local variations in fallout deposition, and sheep bone tissue is available in areas of Australia where other representative samples are difficult to obtain.

The first collection of sheep bones was made from 13 widely separated areas during May–June 1957, and further collections were made from 16 areas in August 1957 and 1958. The grazing localities are shown in Fig. 3. In each case representative long bones were selected from the legs of up to three sheep each of which had grazed over natural grasses throughout most of its life.

In all, 59 analyses were performed on material collected from 89 sheep during the three surveys and

the results are shown in Table 4 Results which are systematically low for all three surveys are apparent for some areas These low values may be associated with variations in rainfall, soil and grazing conditions

However, Table 4 also shows that the mean strontium-90-level in yearling sheep bone is virtually constant for the three successive surveys This implies that the strontium-90-levels in sheep bone tissue of this age depend mainly on the rate of deposition of fallout, lending support to Russell's[26] recent suggestions concerning the relative roles of total fallout and the fallout rate in the take-up of strontium-90 into plants

Apart from the systematic variations at particular locations referred to above, the skeletons of yearling sheep throughout Australia appear to be contaminated with strontium-90 to approximately the same extent Fallout is therefore uniform across the continent, the slight latitudinal variation suggested by other measurements[27] is not reflected in these results

(*e*) *Soil* During August 1957 and 1958, samples of soil to a depth of 10 cm were taken from uncultivated land within each of the five capital cities At each site succeeding samples came from the same immediate vicinity but the sites themselves were associated with neither milk production nor market gardening The surface dimensions of the samples lay between 0 04 and 0 05 m ^{2}, the surface matt was analysed with the soil

The 10 samples were treated using the hydrochloric acid leaching method, which is considered to give complete extraction of both calcium and strontium-90 The analytical results shown in Table 5 would imply that within the errors there has been no overall accumulation of strontium-90 in Australian soils during the period of the investigation This conclusion is unacceptable because measurements of total precipitation collected in open pots at eight sites in Australia during part of this period, and discussed below, suggest an annual deposition rate of nearly 1 mc /km ^{2} This figure is similar to that reported for Australia by Alexander[27], in the course of a world-wide survey of strontium-90 in soil, his results for 1956 and 1958, for samples taken at six Australian sites, are shown in Table 6

* (1) Top 15-cm soil plus surface matt, (2) two samples of 0 126 m ^{2} were taken on each occasion at each site Results quoted are averages

This conflict between the two sets of results is most probably related to certain characteristics of the soil samples Although the same sites were revisited annually, as Table 5 shows, the samples showed considerable fluctuations of density and calcium content and such factors might account for the low values recorded for the accumulated deposit of strontium-90

Taken at face value the present data lead to a mean level at August 1958 of about 2 5 mc /km ^{2}, somewhat lower than the mean value, 3 0 mc /km ^{2}, of Alexander's data for Australia

(*f*) *Total Precipitation* Commencing in June 1958 stainless-steel pots, 12 in in diameter and 12 in high, were exposed continuously at the eight stations shown in Fig 3 This aspect of the fallout monitoring programme was carried out in co-operation with the U S Atomic Energy Commission, as part of its open-pot sampling effort[6–9]

Both precipitation and solid deposition were collected over monthly periods and in each case the

catch was analysed for strontium-90 by the Health and Safety Laboratory of the U S Atomic Energy Commission, the results are shown in Table 7

Taking into account the seasonal variation in fallout rate the mean annual rate of deposition of strontium-90 for Australia approximates to 1 mc / km^2 Further work, now in progress, will establish this rate more definitely

Comparisons of Australian Strontium-90 Levels with those in the Northern Hemisphere

The nearly uniform fallout of strontium-90 in Australia contrasts with considerable fluctuations observed in the United Kingdom and the United States, where the bulk of northern hemisphere measurements have been made Nevertheless, rough average levels can be compared in those cases where data are available for the appropriate time (the United States does not measure sheep bones or cabbages)

The human bone results given in Fig 2 show that the Australian levels are somewhat less than one-half those for the northern hemisphere In the cases of milk and cabbages, comparisons with American[6-9] and British[4] data again indicate levels which are about one-half the northern hemisphere values while Australian sheep bone results for 1957 indicate levels less than one-half those in the United Kingdom[4] at that time

Australian soil-levels lie between one-fourth and one-third of those of the more densely populated regions of the northern hemisphere[27], while the open-pot measurements indicate a strontium-90 fallout rate of less than one-quarter that operative in the northern hemisphere

Conclusions

(1) Within the sampling errors, and apart from some local variations noted, the levels of strontium-90 in the material examined are uniform throughout Australia This indicates that the strontium-90 fallout over the continent arises from high-yield fission weapon tests overseas. as expected the contribution from local weapon tests is too small to be detected

(2) The rate of deposition of strontium-90 and its accumulation in Australian soils are one-fourth to one-third those in the more densely populated areas of the northern hemisphere The levels of strontium-90 in Australian human bone tissue and milk lie between one-third and one-half those in the northern hemisphere This level is a little higher than would be expected from the fallout rate and the soil data, but the difference is not established statistically If further experiments prove this difference to be real it would be hard to explain satisfactorily

A similar difference between bone and soil-levels was reported by Kulp *et al* [23] for other southern hemisphere samples and they considered that it might be due to the movement into the southern hemisphere of foodstuffs containing strontium-90 produced in the northern hemisphere This explanation is unsatisfactory in the Australian case for the continent is self-sufficient in most primary production, especially of milk and cereals Further results from the Australian survey should elucidate the position

(3) The possible biological consequences to the population of Australia, of the fallout-levels reported in this paper, have been assessed by the Australian National Radiation Advisory Committee[28] The Committee concluded that the possible hazards are very small in comparison with those already accepted in technically advanced communities

EVOLUTION OF HOST–PARASITE RELATIONSHIPS

PROF JEAN BAER (Neuchâtel) opened a symposium held by Section D (Zoology) at the recent British Association meeting in York on the "Evolution of Host–Parasite Relationships" He began by analysing an ecological survey of such relations The survey was limited to biting and sucking lice, fleas and worms parasitic in vertebrates, because the taxonomy and host-distribution of these parasites have been well studied, their life-cycles are usually complex and diverse and their host-relations show great diversity

The host or host-group is comparable ecologically to an island, the parasites representing the endemic fauna, and the more isolated the island, or the more specialized the host, the higher is the degree of endemicity of its fauna There is a great deal of evidence showing that both morphological and physiological specialization of the parasites is a consequence of their adaptive evolution to distinct groups of hosts

A reliable impression of host-distribution can be derived from histograms of the numbers of genera of parasites in particular host classes, and from the individual distribution of each group may be deduced its probable age

Mallophaga, for example, occur exclusively on birds and mammals, and have evolved more extensively on the former than on the latter Monogenea are parasites on elasmobranchs, teleosts, amphibians and reptiles but are far more widely specialized on teleosts than on elasmobranchs and only very slightly on amphibians and reptiles Cestodes occur throughout all the major groups of vertebrates , the greatest number of genera is found in birds and in elasmobranchs, whereas the largest number of genera of trematodes is found in teleosts even though trematodes have been reported from all the major groups of vertebrates

Host–parasite relationships as expressed by the number of genera of parasites associated with a given group of hosts also imply that the age of the parasites, that is, the time when they first adopted parasitism as a way of life, varies considerably For example, fleas, lice and Mallophaga are unknown from hosts other than birds and mammals and it is extremely unlikely that such parasites existed before their hosts themselves appeared in late Cretaceous times Monogenea and cestodes were already most certainly associated with the precursors of modern sharks and appear to have accompanied the aquatic ancestors of the land-dwelling vertebrates Moreover, ectoparasitic Monogenea have only been able to survive by seeking refuge within the mouth cavity, œsophagus and urinary bladder of their hosts, and since their life-cycle restricts them to an aquatic habitat, they are associated with vertebrates such as amphibians and freshwater tortoises On the other hand, tapeworms living invariably within the gut of their hosts have evolved together with the latter and, as their life-cycles also became adapted to terrestrial intermediate hosts, it is natural that these parasites occur in land-dwelling vertebrates, that is, in reptiles, birds and mammals

These parasites of vertebrates were discussed ecologically, separately as ectoparasites and as endoparasites, and as to whether the larval forms had a free-living stage or not The ectoparasites with no free-living stage were the Mallophaga and the Anopleura, and with a free-living stage, the terrestrial Siphonoptera, and the aquatic Monogenea The endoparasites were those with a gradual metamorphosis, the nematodes, which might or might not have an intermediate host, and those in the metamorphosis of which distinct stages occurred, the trematodes, cestodes and Acanthocephala, all of which had at least one intermediate host

An analysis of the results from an ecological approach to host–parasite relationships clearly shows the presence of two factors responsible for host distribution, namely, (*a*) the physiological requirements of each of the stages of the life-cycle , (*b*) the degree of morphological differentiation of the infestive larval stage These factors, being inherent to the class to which the parasite belongs, must have been acquired genetically and are therefore subject to mutation and to evolutionary pressures

Each successive stage of any life-cycle does not necessarily have identical physiological requirements, but the more highly specialized the latter the greater the degree of intimacy between the parasite and the host In trematodes, for example, host-specificity for the first intermediate host is more pronounced than in any of the subsequent stages, whereas in tapeworms the greatest degree of intimacy occurs with the definitive host In trematodes and acanthocephalians the infestive larval stage is already a completely formed young worm that only needs to mature and to grow to become adult Since the distribution of these parasites in their definitive hosts mostly follows the ecological pattern, it is probable that the physiological requirements of the adult worms are not highly specialized On the other hand, the infestive larvæ of monogeneans and tapeworms on reaching the definitive host must undergo further metamorphosis before acquiring adult characters The necessary conditions appear to be very strict and the more considerable the metamorphosis the greater the degree of host-specificity, the latter following the phylogenetical pattern Although there is, as yet, insufficient evidence for parasitic nematodes, it seems, however, that there might be a specific mechanism that triggers the final moults of the infective larva

Free-living flea larvæ require strict conditions as to temperature and degree of humidity, implying that their physiological requirements may be rather specialized But the legendary mobility of adult fleas and their resistance to starvation enable them to survive, but not necessarily to reproduce, by practising the art of host-hopping

During their entire life-cycle, biting and sucking lice remain attached to the host So it is not astonishing that their physiological requirements appear to be highly specialized as regards hair and feather structure In birds, their host distribution appears to reflect principally the latter

Summing up the effects of both external and internal factors responsible for parasite relationships we find that parasites do not select their habitat but that the latter is imposed by ecology The resulting distribution, however, also reveals another selective mechanism, namely, the degree of physiological and morphological adaptation of the parasites themselves

Prof W E Kershaw (Liverpool School of Tropical Medicine), in discussing the evolving human filariæ, suggested that it was more pertinent to consider their present evolution rather than what had happened in the past This was possible because of precise information of those pathogenic human parasites which it had been necessary to obtain urgently in order to devise economic and practicable control measures Their complicated life-cycles involved man, possibly other animals, and usually multiple species of vectors, each vector with its own sequence of environments The parasite, therefore, should be regarded as one component of a parasite–host–vector complex The true evolving entity was therefore not the parasite but the complex, which was evolving as were the separate components, and it was behaviour rather than structure which was critical

Loa loa, a parasite responsible for the recurrent and crippling so-called Calabar swelling, occurs in West and Central Africa There were two parasite–

host–vector complexes, an infection occurring in man and transmitted by two species of the vector genus, which bite during the day, and another occurring in three or more species of monkey which are adapted to different but related species of the vector which bite during twilight and at night. Both parasites were very closely related and differed only in their general dimensions and in their adaptation to different vectors. Each was well tolerated by the different vertebrate hosts and equally well transmitted by all the related vectors in the laboratory, but little interchange between these two populations occurred in Nature.

Malayan filariasis caused recurrent lymphatic inflammation and fever and often resulted later in the disabling permanent swelling of the limbs and the genitals known as elephantiasis; one form occurred in the north-west (periodic) and the other in the south and east of the Peninsula (non-periodic). The parasites responsible had only trivial structural differences, differing mostly in behaviour. In the 'periodic' form the larvæ were rarely found in the blood during the day, being most numerous at night. In the 'non-periodic' form, the larvæ were apparent during the day and night in similar numbers. The larvæ of these two forms behaved differently in the blood, they had different groups of vectors, and though both could be transmitted easily to cats, one form is not so well adapted to animals and occurs naturally only in man; whereas the other form is well adapted to animals and occurs naturally in man, in several species of monkey, in the domestic cat and in the pangolin.

In addition to these two infections in man, one of which is shared with many animals, there was a further and separate parasite which behaves a little differently from the other two, was transmitted by vectors somewhat different from the others and occurred in a very large range of animals, including the dog, the domestic cat, two species of wild cats and the civet cat, the tiger, the pangolin, the moon-rat and the slow loris, and could be transmitted experimentally to man and to the domestic cat. It had so far been found in the State of Pahang.

Work in East Africa had disclosed a fourth parasite, occurring in animals but not so far in man, closely related in structure to the two forms of human filariasis in Malaya and to that described in the State of Pahang occurring in a large range of animals. There were four related parasite–host–vector complexes, one of which had separated from the other three and was so far believed to be restricted to East Africa, and three occurred in Malaya. These three in Malaya are now evidently undergoing further divergent evolution, though their overlap is still very considerable.

Onchocerciasis caused skin changes and was associated with blindness in Central America and in tropical Africa. In the Americas, the adult worms occurred in nodules in the head and neck and eye changes were common, while in Africa they occurred on the lower part of the trunk and the legs, and eye changes were less common and occurred mostly in old-standing infections, so that they were once thought to be due to different parasites. In Africa the distribution of the larvæ in the skin had a very clear pattern both on the surface and in depth, and in early infections these larvæ were limited to the legs. Only when exposure to the infection had been repeated for many years did the concentration of larvæ rise and were they to be found in the upper parts of the body. While similar precise information was lacking in the Americas it seemed likely that the larvæ were most numerous in the head and neck. The vectors in Africa bit on the ankle and leg, and in America on the head and neck. These two different parasite–host–vector complexes have the same host and the same parasite, but differ in their manifestations because of the different behaviour of the two different groups of vectors.

The fundamental research undertaken to make it possible to devise economically practicable control measures has disclosed evolution in progress.

Dr. C. A. Wright (British Museum, Natural History) discussed the relation between trematodes and molluscs. The problem of speciation in the digenetic trematodes had received little attention. Isolation of some kind is an essential factor in the evolution of new species, and it is suggested that the part played by the molluscan intermediate host is of considerable importance in the speciation of flukes. The effective geographical range of a parasite is that area where all of the hosts necessary to the completion of the life-cycle occur together. The ecological requirements of most molluscs are such that a species is seldom uniformly distributed throughout its range but is broken up into separate populations between which there are varying degrees of isolation. These populations serve as the foci for the completion of fluke life-cycles and it is around these centres that the gene pools are formed from which new species may arise. There are three main factors in the maintenance of the purity of the gene pool, the geographical isolation of the locality, movement of the definitive host and the longevity of the adult parasite within that host. The third factor may partly offset the second for, if the parasite matures quickly, lays its eggs and dies, there is less chance of the eggs reaching other centres where the cycle could be completed even if the definitive host is very mobile.

The importance of host-restriction in the parallel evolution of host and parasite is of great significance, and the degree to which this phenomenon is shown in the relationship between larval flukes and their molluscan hosts is far greater than it is between the adult flukes and their vertebrate hosts. In those flukes which have a free-swimming miracidium there are at least two ways in which new fluke–mollusc relationships may occur. In the process of host-location by the miracidia the first stage is a response to physical stimuli which bring the larvæ into the region of the host-habitat. Thus, the substitution of a different mollusc having the same ecological requirements as the normal host may result in the adoption of this new host if its tissues provide an acceptable environment for further development of the larvæ. The last stage of the host-finding pattern by miracidia is a response to a chemical stimulus. Paper chromatography has shown the presence of species-specific substances in the body-surface mucus of freshwater snails and it is possibly these substances which enable miracidia to discriminate between potential hosts. It has now been shown that there exist differences in the composition of the mucus of snails of the same species from different populations and this may have great significance in the evolution of new mollusc–fluke relationships.

Dr. Theresa Clay (British Museum, Natural History) made some suggestions about the evolution of host–parasite relationships in the Mallophaga of birds. It was possible that the breaking up into non-breeding units by the birds during their evolution would result in isolated populations of Mallophaga and was analogous to the situation found on a group of continental islands the populations of which had become isolated by the disappearance of land connexions Later secondary infestations of Mallophaga from one host group to another are analogous to the trans-oceanic colonization of oceanic islands Successive colonizations and the occupation of the different ecological niches on the body of the bird could explain the number of different genera and species of Mallophaga found on one host species During the time that the Mallophaga were still partly free-living and before they had developed any close adaptation to life on the bird or to a particular bird species, interchange of host was presumably more frequent Thus, although birds within an order or sub-order are usually parasitized by related mallophagan faunas which have presumably evolved on these orders, the origins of related mallophagan faunas on different orders are difficult to assess In the affinities between mallophagan faunas of the birds[1], a diagram meant to demonstrate factually these affinities and not necessarily to suggest affinities between the host groups, the similarity of the mallophagan faunas of the Procellariiformes and those of the Charadriiformes, for example, may show no more than an ecological relationship, members of both orders living in the same environment The fact that in general the species on the two orders are now well differentiated suggests that, if this distribution is due to secondary infestations, it could not have been recent and supports the theory that establishment on a new host took place mainly in the early days of the evolution of host and parasite

Mr P F Mattingly (British Museum, Natural History) stated that the complete restriction of human and simian malaria to anopheline vectors suggests that this group may originally have evolved mainly as feeders on mammals Bird malaria, on the other hand, was carried exclusively by culicine mosquitoes which might thus have originated as feeders on birds The fact that human filariasis was carried by both anopheline and culicine mosquitoes suggested that it may have entered the system comparatively recently The comparative physiology and biochemistry of blood-meal utilization in mosquitoes had been very inadequately studied This was a particularly promising field for research which might throw light on many problems

Prof G C Varley (Oxford) believed that host specificity needed careful definition Not only must both host and parasite be accurately identified, but also those cases where a parasite can only complete part of its development must be distinguished Published lists unfortunately often gave equal emphasis to unique records and to regular parasite relationships

Prof Baer considered that the relation between a parasite and a group of hosts, related by ecology or phylogeny, was biologically significant, whereas the relation between one parasite and one host meant little

Prof Baer believed that the biochemical approach to species determination should be encouraged in the way that Dr Wright was applying it to snails, and that isolated proteins and carbohydrate fractions from hosts and parasites might be used

Dr J Sandground (New York) described his experience with onchocerciasis in Guatemala and in the Gold Coast, and referred to his demonstration some twenty years ago that the parasites in the New and Old World were identical He believed that much more work remained to be done in onchocerciasis before the infection could be understood adequately and before control would be easy

WILLIAM KERSHAW

---

[1] Clay, T, First Symposium on Host Specificity among Parasites of Vertebrates, Neuchâtel, 120 (1957)

ANIMAL CLOCKS

THE significance of rhythmic activities in animal physiology is becoming increasingly evident to-day For this reason, the symposium on 'animal clocks' held in York on September 4, by Section D (Zoology) of the British Association for the Advancement of Science, was well timed During the morning sessions, Dr L Harrison Matthews, section president, was in the chair

The first speaker, Prof F A Brown, jun (Northwestern University), described recent research carried out in his laboratory In 1948 he had established that the frequency of the rhythm of colour change in fiddler-crabs was independent of temperature over a 20-deg C range Later it was shown that this 'indicator' process was itself regulated by a more fundamental rhythmic element and that two control centres were involved Although the concept of an autonomous clock is retained by most investigators, Prof Brown now postulated that the periodisms which comprise basic biological clock systems are imposed by environmental changes even in conditions hitherto presumed to be constant This hypothesis he supported by a detailed statistical analysis of data obtained by means of an automatic recording respirometer from organisms as unrelated as fiddler-crabs and potatoes which had been hermetically sealed in constant conditions including pressure, for several days at a time

Although other speakers did not agree with this view, all must have been stimulated to look more carefully at their own data Unfortunately, it has so far proved almost impossible to devise a really critical experiment that will differentiate between an innate clock mechanism and one derived from exogenous sources, since it appears possible, by analogy, to alter the position of the hands of the clock relative to the works Just as it is difficult to conceive of a distance-judging mechanism independent of space, so a clock system presumably requires some fixed points of reference

In a paper on the influence of the environment on the cyclical biting-behaviour of mosquitoes, Dr A J Haddow (director of the East African Virus Research Institute) pointed out that every species so far studied has shown a 24-hr periodicity In some, this is merely nocturnal or diurnal, but in others most of the activity is confined to one or two short and precisely delimited periods These, while usually very constant for a given environment, may be entirely different in another Further, they may show very striking differences at different levels above ground within the same environment At present, no single explanation fits all known cases

The complexity of natural internal timing mechanisms was illustrated by Dr Janet Harker (Department of Zoology, Cambridge), who described a series of elegant experiments by which she had been able to slow down part of the mechanism In cockroaches a hormone has now been discovered which increases the activity of the animal, and which is secreted in strict 24-hr cycles This hormonal clock can be stopped by chilling the secretory cells while the rest of the body is kept at a normal temperature, and when this is done a second clock associated with the nervous system is revealed When the secretory clock is allowed to start again, provided it has not got too far out of time with the nervous clock, it is reset by the latter However, in normal conditions the secretory clock acts as the master-clock, and since, like the nervous clock, it is not affected by sudden short changes in light conditions, the diurnal activity rhythm of the animal is little upset by such changes This may be important, in Nature, for animals which experience short periods of darkness during the day (for example, by going under a stone), or light at night (for example, bright moonlight or artificial light) If these minor changes in light conditions were to reset the clock, the animal would soon get out of time with day and night On the other hand, the fact that the secretory cycle can be affected by the nervous system clock towards the beginning and end of the dark period, and the activity rhythm can be immediately reset at these times, suggests a way in which the animal can allow for changing day-length

The morning session closed with an account by Dr C S Pittendrigh (Princeton University) of a coupled oscillator model for studying the behaviour of the innate circadian ('about a day') rhythm of cells and organisms Its further utility was noted in explaining recent discoveries in thermo- and photoperiodism Studies on the effects of single perturbations of the oscillator by light or temperature reflect the behaviour of a common underlying biological mechanism in some organisms, the phase of a rhythm can be shifted by a light signal as short as 1/2,000 sec It was concluded that the cell must comprise many diverse circadian oscillations, and disturbances of their mutual phase relations may lead to physiological stress or damage

Prof G C Varley (University of Oxford) presided over the afternoon sessions in which plant clocks were described by Dr M B Wilkins (King's College, London), with special reference to his own observations on excised leaves of *Bryophyllum fedtschenkoi* placed in continuous darkness and temperature These maintain a 22 4-hr rhythm in the rate of carbon dioxide output for several days The clock controlling the rhythm is extremely sensitive to changes in external conditions of temperature and illumination to which the leaves are subjected Continuous illumination inhibits the clock which re-commences when darkness is restored, the phase of the subsequent rhythm being determined by the time at which the light was extinguished The phase of a rhythm persisting in darkness is reset by applying a 3-hr light treatment to the leaves between the peaks but not at the crest of a peak Red light inhibits the rhythm, but blue light has no effect A rhythm can be induced in illuminated leaves by reducing the light intensity by at least 80 per cent, and it was later found that the phase of such a rhythm could be reset by applying a 3-hr dark treatment at the crest of a peak, but not between the peaks The rhythm is inhibited when the tissue is placed in an atmosphere of nitrogen and its period varies with temperature It is apparently unaffected by solutions of mitotic inhibitors such as phenylurethane and colchicine

Dr C G Butler (head of the Bee Research Department, Rothamsted Experimental Station) then surveyed the development of knowledge regarding the time-sense of the honey-bee since its fortuitous discovery in June 1905 by the famous naturalist, A Forel It was not until more than twenty years later that Ingeborg Beling carried out her extensive experiments in which bees were trained to visit a feeding place at different times of day under constant conditions Later workers have since obtained data which support the view that a honey-bee's time-sense depends in some way upon metabolic rhythm, since it can be speeded up or slowed down by the use of appropriate drugs Finally, bees trained in Paris to visit a feeding dish at a definite time each day have continued to maintain their feeding schedule under constant conditions after being flown to New York, thus demonstrating that the time-sense of the insects is endogenous

Dr A J Marshall (St Bartholomew's Hospital Medical College) introduced an exotic note when he discussed the possible influence of the internal rhythm of reproduction in the control of trans-equatorial migration of birds flying between Europe and Africa and Tasmania and the Aleutian Islands He pointed out that although something akin to a clock was involved, it had to be likened, nevertheless, to a somewhat imprecise, chain-store variety in that it had to be 'corrected' by environmental factors at least once during each annual cycle Work carried out by Dr D L Serventy and himself had made it clear that even when shearwater petrels (that breed on islands off the Southern Australian coast) were kept captive under widely varying conditions and day-length, they nevertheless came to breeding condition at the same time as the free birds that had made their astonishing circum-Pacific, trans-equatorial journey

Next, Dr J L Cloudsley-Thompson (King's College, London) discussed the synchronization of animal clocks in general, pointing out that endogenous rhythms are frequently correlated with environmental changes although they are not necessarily a direct response to them Thus, if cockroaches are subjected to alternating 12-hr periods of light and darkness, locomotion may actually begin shortly before the light is extinguished We have therefore the concept of an innate rhythm synchronized by changes in environmental factors such as light, temperature and humidity which should be regarded as 'clues' rather than stimuli

The field cricket, *Gryllus campestris*, placed in aktograph apparatus, can be seen to be active in the day-time with a rhythm that is endogenous and independent of temperature When the 24-hr periodicity has died away, however, after weeks in constant conditions, it can be re-established by a single exposure to light or by a return to higher temperatures after a period at 5° C The cricket's clock can be reset in this way, even when activity is completely suppressed by drought

Although light intensity is the chief factor by which animal clocks are synchronized, regular temperature changes can also be effective When night-active animals such as white rats, deer mice and millipedes are placed in constant light, it is found that their rhythms tend to be delayed while those of day-active forms are accelerated. The converse often occurs in constant darkness. In this way, diurnal rhythms can be shifted as the days lengthen or draw in according to the season. Synchronization with environmental changes cannot be achieved both at dawn and dusk as the time of each of these is altering. The 'clue' tends to be dusk in the case of nocturnal forms, dawn in that of day-active animals.

The symposium concluded with a paper by Dr. Mary C. Lobban (Department of Physiology, Cambridge), who said that in most communities man's activities are geared to a 24-hr. day. The clock which governs this periodicity is often difficult to reset, as those who travel great distances at the speed of modern aircraft well know. It is, however, possible to separate different physiological rhythms and to get them adapted to different degrees and at different rates. Recent work with indigenous Arctic peoples—Indians and Eskimos—indicates that environmental factors may influence physiological diurnal rhythms more than was hitherto thought. Temperature and physical exertion may well exert a profound effect in deciding whether an individual will become adapted successfully to a new time routine and even whether he will become adapted at all.

Both sessions were followed by lively discussions which served to emphasize the diversity of approaches to be found among workers on rhythmic phenomena. For example, Dr. William Gooddy (London) noted that no definition of a clock had been given by any speaker: the papers were concerned with the forms of rhythms and their possible causes. The definition of a clock as some form of regularly repeated natural phenomenon implies the presence of an observer, and each speaker had mentioned only those rhythmic processes which he had selected to be clock-forms for him. Since it is possible to study innumerable time systems, from the human time sense to the 'tides' inside single cells, the multiplicity and interaction of the mechanisms are evident. It might be wise to investigate organisms with nervous systems separately from plants. Though the cycles of some systems are related to the great events of astronomical observation, they will be modified by all other systems, perhaps giving rise to circadian cycles rather than exact 24-hr. cycles. Final or simple rhythms of an organism, including those described, must represent the average effect of all the possible clock forms observable by biologists in that organism. Too much analytical work on a system in isolation might obscure the general principles which may one day explain the mysteries of the human time sense.

Mr. P. F. Mattingly (London) pointed out that the study of arthropod-borne virus diseases had made it abundantly clear, despite the isolation of the virus in an intracellular environment, that its evolution has been conditioned by external factors no less than has that of the host. The integration of cyclical rhythms in animals is not merely a physiological problem but forms the basis of organic evolution itself.

Dr. E. T. Burtt (Newcastle upon Tyne) inquired whether different rhythmic activities might not profitably be regarded as portions of a continuous spectrum, but Dr. Cloudsley-Thompson replied that he believed there to be a hierarchy of mutually regulatory rhythmic patterns. Another speaker suggested that perhaps too much work had been devoted to arthropods, since inter-cellular transference of hormones is not the same in these animals as in vertebrates. (An instance is afforded by the sex hormones, the inter-cellular movement of which is so much reduced among insects that mosaic individuals can be formed.)

Dr. Sydney Smith (Cambridge) emphasized the dangers of lumping together a number of unrelated phenomena under ill-defined names such as rhythmic, or cellular activity—a trait as seductive as it is misleading. Finally, Dr. Harker pointed out that under conditions of desiccation the distribution of hormones within the insect body becomes blocked, owing to reduction in the amount of blood. This would explain the phenomenon observed in the field cricket.

J. L. CLOUDSLEY-THOMPSON

THE CONTINUED PROGRESS OF SATELLITE 1958δ_2 (SPUTNIK III)

By B. R. MAY and D. E. SMITH

Radio Research Station, Department of Scientific and Industrial Research,
Ditton Park, Slough, Bucks

THE progress of the third Russian Earth satellite, 1958δ_2, from launching on May 15, 1958, until October 31, has already been reviewed by D. G. King-Hele[1]. From the latter date the responsibility of following the progress of the satellite and predicting its flight was taken over by the Radio Research Station, Slough.

For prediction purposes a period–time curve has been plotted, using radio and optical observations, and this is shown in Fig. 1. It is noticeable that the slope of the curve has been decreasing steadily throughout the period December–April: from November 1 to December 20, 1958, the mean rate of change of period was about 1.26 sec./day, from December 20 to February 28 about 1.17 sec./day, and from February 28 to March 31 about 1.11 sec./day. This decrease in slope, which arises from a lessening of atmospheric drag, is very probably a consequence of the fact that the southerly latitude of perigee, the point in the orbit at which the satellite experiences the greatest atmospheric drag, has been increasing since October 24, the date on which it crossed the equator. This movement has resulted in a net increase in the height of perigee above the Earth's surface, since the rate at which the Earth's radius has been decreasing with latitude has been greater than the rate at which the perigee distance of the orbit has been decreasing. A lessening

Table 1 ORBITAL ELEMENTS FOR SATELLITE $1958\delta_2$

Date	Nodal period of revolution (min)	Semi-major axis (km)	Eccentricity	Perigee distance (km)	Apogee distance (km)	Orbital inclination (deg)	Rate of rotation of orbital plane (deg /day)	Argument of perigee (deg)

Note Upper figures in columns 4, 5 and 6 were obtained assuming a scale height of 55 6 km (30 nautical miles), the lower figures correspond to a value of 37 1 km (20 nautical miles)

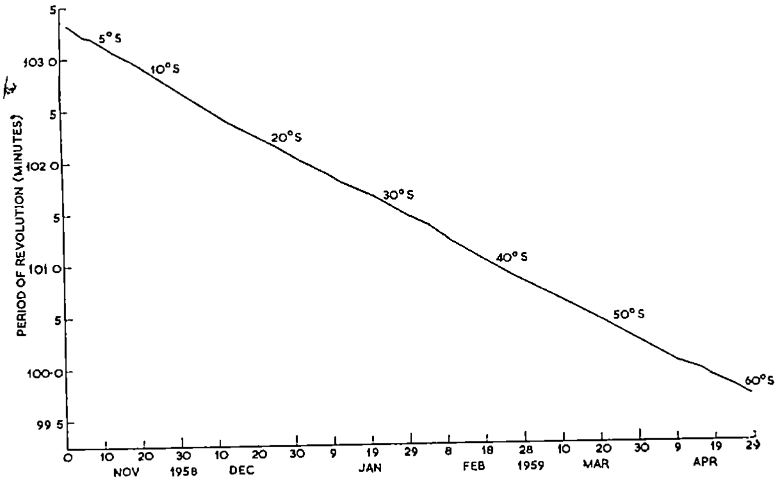

Fig 1 Nodal period of revolution of satellite $1958\delta_2$ (*Sputnik III*) Numbers on curve indicate latitude of perigee

of atmospheric drag follows from this increase in height Some idea of the increase in perigee height with increasing southerly latitude can be obtained from the following figures at latitudes 0°, 40° S and 60° S , the perigee heights were 210 9, 216 4 and 222 5 km , respectively, for a scale height of some 46 km (25 nautical miles) It is interesting to note that since March 25, 1959, the perigee of *Sputnik III* has been at a greater latitude than any other established satellite

Superimposed upon the smooth curve are numerous irregularities implying changes in the effective cross-sectional area of the satellite, or as is more likely, irregularities in atmospheric density at perigee Suggestions have been made as to the causes of these irregularities—discontinuities of density at the boundary of the light and dark sides of the Earth[2], solar disturbances[3]—though a discontinuity at about 28° S , corresponding to one detected at about 28° N by King-Hele[4], has failed to make an appearance

The irregularities in the period - time curve have made it difficult to forecast with any certainty the date of descent of the satellite During December 1958 a theoretical date of descent of about December 15, 1959, was indicated, but at the present time the expected date is nearer January 5, 1960

As an object for optical observations, the satellite has been comparatively faint since October 1958 due to its height, which has not been less than 460 km in the latitude of Great Britain On only a very few occasions has it been observed visually at stellar magnitudes brighter than + 3, and most observations have been made at magnitudes + 5 to + 7 During May, when the satellite was visible two and three times each night, its brightness remained fairly constant (though of an unpredictable magnitude) on any one transit, in contrast with the flashing nature of its appearance earlier this year The satellite is still transmitting on a frequency of between 20 004 and 20 005 Mc /s , though it has been reported from Australia[5] that the satellite does not now transmit a modulated signal when it is in the Earth's shadow Radio observers in Great Britain have had little opportunity of verifying this since, on transits within radio-range, the satellite has not been in the Earth's shadow since April 28

The initial elements of the orbit of the satellite, for epoch May 15 3, 1958, were nodal period, 105 975 min , eccentricity, 0 111 , perigee height, 226 km , apogee height, 1,879 km , and argument of perigee, 58° The elements for the period November 1, 1958–May 1, 1959, are given in Table 1 The nodal periods have been taken from the period - time curve used for prediction purposes The semi-major axis, eccentricity, perigee distance, apogee distance and the rate of rotation of the orbital plane have been calculated from the periods[6] The orbital inclination has been obtained by comparison with *Sputnik III* rocket ($1958\delta_1$), and the argument of perigee from a mean curve plotted using values from various sources including the Smithsonian Astrophysical Observatory As the value of the scale height at heights in the region of the perigee is uncertain, the eccentricity and the perigee and apogee distances have been calculated using two values of scale heights, 55 6 km and 37·1 km., the limits within which the true value is thought to be.

We should like to take this opportunity of thanking all those who have sent us observations on satellite $1958\delta_2$, both radio and optical.

The work described above was carried out as part of the programme of the Radio Research Board and is published by permission of the Director of Radio Research of the Department of Scientific and Industrial Research.

OBITUARY

Sir Ian Heilbron, D.S.O., F.R.S.

SIR IAN HEILBRON died in London at the age of seventy-two, following a short illness, on September 14. He was born in Glasgow in 1886, was educated at the High School and graduated from the Royal Technical College there. He had, as he was fond of recalling, decided upon chemistry as his career against family advice, but his choice was soon confirmed under the inspiring guidance of the late Prof. G. G. Henderson, for whom Heilbron acquired a life-long admiration. It was at Henderson's suggestion that Heilbron spent a two years tenure of a Carnegie fellowship from 1909 with Hantzsch in Leipzig. Here, a close companion of the late Prof. R. Robison, Heilbron developed a lasting interest in the application of spectroscopy to structural organic chemistry, and this experience seems to have led to the emergence of one of his marked characteristics, namely, a constant readiness to extract all possible assistance in the study of natural compounds by applying new physical techniques such as molecular distillation, chromatography and countercurrent distribution. However, his academic career at the Royal Technical College, Glasgow, where he was lecturer until 1914 and where he worked in purely synthetic organic chemistry, was interrupted by the First World War, in which he served with great distinction, eventually as assistant director of supplies in Salonika, and was awarded the D.S.O. After the War, he spent a short time with the then newly formed British Dyestuffs Corporation, but soon embarked upon a brilliant academic career, in which he successively held professorial chairs in Glasgow (1919–20), Liverpool (1920–33), Manchester (1933–39) and London (1938–49).

Heilbron's great and pioneering contributions to the study of natural compounds commenced in Liverpool. His early studies on the constituents of fish liver oils, notably squalene, led in turn to his introduction into Britain of micro-methods, to further his many investigations on the fat-soluble vitamins A and D, with which was associated in due course still wider exploratory work on steroids and carotenoids generally. It is perhaps ironical that he himself rarely shared fully in the culminating synthetic triumphs which were often based on the difficult and arduous work which he had long ago instituted with such conspicuous acumen, courage and determination. However, outstanding as were his many direct contributions to knowledge, as reflected, for example, in some three hundred original publications, and his bringing into being with H. M. Bunbury the "Dictionary of Organic Compounds", his indirect contributions to chemistry in general were perhaps unequalled. Repeatedly he equipped laboratories with unsurpassed vision so that each is now a thriving centre of research. Above all, he inspired a host of younger chemists, many of whom now occupy leading positions in universities or industrial life in Britain and abroad.

The Second World War naturally brought Heilbron again to the service of his country ultimately as scientific adviser to the Ministry of Production, where he played an important part in introducing DDT, and as a result was knighted in 1946. All these duties, discharged with a precision and penetration which constantly surprised his associates, were assumed, however, in addition to his academic work, which went on at an accelerated rather than a reduced rate and led later to a new spate of publications on such different topics as the chemistry of the steroids, acetylenic compounds and penicillin. Moreover, by this time his unique experience was widely sought in such capacities as chairman of the Colonial Insecticides Committee, as a member of the Advisory Council of the Royal Military College of Science and of the Advisory Council to the Committee of the Privy Council for Scientific and Industrial Research, and in reorganizing the International Union of Pure and Applied Chemistry. While in the midst of these activities he relinquished his academic post at the Imperial College of Science and Technology, London, to become director of the Brewing Industry Research Foundation (1949–58), which owes so much to his versatility, energy and genius.

Heilbron's scientific life began when the study of chemistry and particularly of natural compounds was scarcely more than an academic pursuit; but he lived to see many of the methods and techniques which he had sponsored become general tools of research and many of his research projects develop into substantial segments of chemical industry. It is not surprising, therefore, that he received wide recognition in the form of numerous awards and honorary degrees, both in Britain and overseas. Any mere catalogue of these achievements and distinctions could, however, convey little real impression of his great qualities as a man. Lucidity, constructive imagination and an almost intuitive insight into the complexities of scientific effort were among many similar characteristics which were almost immediately apparent to all with whom he came into contact. Those somewhat closer, as in the departments which he directed, came also to recognize his generosity, scrupulous fairness and invariable feeling of fatherly concern for even the most junior members of his staff. To those privileged to know him still better, his quick sense of humour, keen appreciation of the arts and, above all, the spontaneous assured wisdom with which his lively mind abounded, made him an unforgettable and delightful personality He is survived by two sons, but the sudden death of his wife, Elda, in 1954 was a sad blow which affected him far more deeply than many who knew him may have realized

A H Cook

My close friendship with Ian Heilbron dates from near the end of the First World War and arose from many common interests and activities These included consultation with industrial research groups, membership of committees under government auspices and tenure at different times of the chairs of organic chemistry at the Universities of Liverpool and Manchester Heilbron was, of course, an illustrious organic chemist whose reputation was world-wide and whose original work could justly be described as pioneering As Dr Cook has pointed out, he did not always enjoy the full fruits of his labours Others stood on his shoulders and were thus enabled to reach higher A part of his work was in fields of potential commercial importance and doubtless for this reason some of his discoveries were impatiently exploited

Heilbron had much courage of his very firmly held convictions, and did not fail in finding words to express them He caused many a breath of fresh air to pass over the conference tables, especially when he thought progress was too slow or where he detected evidence of red-tape mentality

His contributions in the Second World War were extremely valuable If he had not been a scientist he could have become a most successful business man and his executive activity was characterized by promptitude and efficiency Every laboratory which came under his charge was greatly improved, not merely by new construction but also by better considered organization of existing facilities His attention to detail in these connexions was very characteristic As an investigator he also excelled in planning the campaign and was instrumental in the introduction of important novel techniques

In private life his friends found him quite charming, an excellent host and a greatly appreciated guest He was fastidious and had a most sensitive appreciation of the fine arts Above all he was a warm-hearted, generous man who devoted himself to public service and to the progress of science

R Robinson

NEWS and VIEWS

Astronomy at St Andrews Prof E F Freundlich

Prof E Finlay Freundlich, who four years ago retired from the Napier chair of astronomy at St Andrews, relinquishes now also his directorship of the University Observatory Prof Freundlich started his astronomical life some forty years ago at the Berlin Observatory Much of his work was determined by an early association with Einstein which made him pursue the question of observational tests of the theory of relativity In order to investigate the predicted red-shift of spectrum lines, Freundlich created in the early 'twenties at Potsdam the well-known Einstein Institute with its tower telescope The new solar installation, among the best of the time, produced new observational evidence on the 'limb' effect, and also important pioneer work on line profiles Freundlich's main contribution to the field of relativity astronomy is undoubtedly his eclipse work on the deflexion of light at the Sun's limb His results of 1929 are still among the best obtained on this extremely difficult problem, and his conclusion that the observed deflexion exceeds the theoretical value is now generally accepted Prof Freundlich left Germany in 1933 and after a few years in Istanbul and Prague settled in St Andrews in 1939 Here he became interested in the design of a large Schmidt–Cassegrain telescope A 19-in pilot model was successfully set up in 1950, and the main parts of the full-size 37 in telescope are now nearing completion In the University, Freundlich instituted an honours course in astronomy, in which he paid particular attention to his favourite subject of celestial mechanics It is pleasing to know that when Prof Freundlich returns to his native Rhineland, an association with the University of Mainz will allow him to retain an active interest in astronomy

Prof D W N Stibbs

Dr D W N Stibbs succeeds Prof E Finlay Freundlich in the Napier chair of astronomy at St Andrews A graduate of the University of Sydney in physics in 1942, Dr Stibbs gained his early astronomical training at the Commonwealth Observatory under the Astronomer Royal, Dr R v d R Woolley , afterwards they were co-authors of the well-known monograph "The Outer Layers of a Star" Engaged as lecturer in mathematical physics at Armidale in 1942, Dr Stibbs was seconded from there to work for the Royal Australian Air Force on the influence of the ionosphere on radio direction-finding He returned to Canberra after the War and was appointed Radcliffe Travelling Fellow in Astronomy in 1951, and worked first at the Radcliffe Observatory, Pretoria, and afterwards at Oxford where he gained his D Phil in 1954 In 1955 he joined the Theoretical Physics Division at the Atomic Weapons Research Establishment, Aldermaston, where he has been engaged in theoretical research on the interaction between radiation and matter under stellar conditions He is probably best known for his fundamental work on the motions of the southern galactic Cepheids as determined from his own consummately planned observations at the Radcliffe Observatory In a discussion of the motion of these stars and of those earlier observed by Joy at Mt Wilson, Dr Stibbs revealed a marked discrepancy in the neighbourhood of the galactic centre between the rotation of the Cepheid System and the neutral hydrogen clouds

California Institute of Technology

Dr Richard P Feynman

Dr Richard P Feynman has been appointed Richard Chace Tolman professor of theoretical physics at the California Institute of Technology The trustees created the new chair in physics in honour of the memory of the late Dr Richard Tolman, an internationally known theoretical physicist and chemist who for years was dean of graduate studies at the Institute Dr Feynman is considered to be one of the world's outstanding theoretical physicists for his contributions to the understanding of atomic structures and quantum mechanics. Recently, in collaboration with Dr. Murray Gell-Mann, of the California Institute of Technology, he developed a theory of weak interactions, which govern the electron and positron in radioactivity. Dr. Feynman graduated from the Massachusetts Institute of Technology and received his Ph.D. at Princeton University. As a scientist with the Manhattan Project, he is credited with making important contributions toward developing the atomic bomb. In 1954 he won the Albert Einstein award, one of America's highest scientific honours.

Ministry of Supply: Director of Materials Research and Development

The retirement of Dr. H. Sutton in August from his present post as director of Materials Research and Development (Air) marks the end of the full-time service of a most distinguished metallurgist who has given the whole of his professional life to the public service. Dr. Sutton was educated at King's School, Macclesfield, took his first degree in chemistry at the University of Manchester, later the degree of M.Sc. and in 1935 he received the degree of D.Sc. In the First World War he served as research assistant to Prof. C. A. Edwards, who was then the regional controller and adviser in Manchester to the Ministry of Munitions. His departure, therefore, severs one of the rare personal links of the present Ministry of Supply with one of its predecessors, the Ministry of Munitions. Joining the Royal Aircraft Establishment at Farnborough in 1918 he was appointed the head of its Department of Metallurgy in 1925, a post he retained until 1943 when he was transferred to the headquarters post which he has built up, largely through his own personal and professional qualities, to the important position it now holds in the field of British metallurgy, especially in relation to aeronautics.

Dr. Sutton was a pioneer in the work on the formulation and fabrication of light metal alloys, without which aircraft in their present form would not be known. He was also early in foreseeing some of the special dangers to which they are subject in relation to crack formation, brittleness and the like. In later years, while never discarding his first interests in aluminium-based alloys, he has been forward in promoting work on titanium and other possible more novel metals. At the same time, as the scope of his duties has widened, he has seen to it that much attention has been given to the non-metallic materials that play so important a part in the construction of modern aircraft. A prolific author of papers on metallurgical subjects published in most of the metallurgical journals, he has been honoured during his career by the award of the Simms Gold Medal and the Silver Medal of the Royal Aeronautical Society. He is a Fellow of the Royal Aeronautical Society, a founder Fellow of the Institution of Metallurgists and a member of all the relevant professional societies. His professional advice has been widely sought by committees in government and industry and he has been unsparing in forwarding those subjects to which he has devoted his life.

The Council for Nature

At the recent annual general meeting of the Council for Nature the following resolutions were passed:

"The Council for Nature fully shares the great concern of naturalists in Britain at the threats to the remaining undeveloped areas of the country's coastline by industrial and other developments and considers that the importance of those areas, both for scientific study and for the conservation of wild life no less than for the preservation of amenity and opportunities for recreation, calls for a halt to the process of spoliation. The Council therefore urges that a meeting of the national bodies interested in the matter should be convened by the Nature Conservancy at an early date with a view to pressing for vigorous action including a review of the principles at present governing the siting of nuclear power stations.

"The Council for Nature welcomes the public-spirited action of a large firm of manufacturers in withdrawing recently their supplies of arsenical spray. The Council, while recognizing the need for the use of toxic sprays (subject to proper safeguard), urges the Government to control the wholesale application of agricultural sprays the cumulative effect of which is still unknown, but which have been, or may be, damaging to so many plants and animals, including such useful insects as bees. The Council urges further that the use of arsenical sprays should be prohibited or restricted forthwith, and that the Government and its agencies should give high priority to the research needed into the long-term effect of toxic sprays on the complex life of the countryside."

Canadian Institute of Oceanography

The Canadian Government as well as the universities are showing rapidly growing interest in the scientific study of the oceans. An annual grant of 90,000 dollars to Dalhousie University was made by the National Research Council of Canada, for the establishment of an Institute within the University to teach and promote research (see *Nature*, 183, 1161; 1959). The Department of Mines and Technical Surveys has now announced its intention to set up a new three-million dollar laboratory in Bedford Basin at the head of Halifax Harbour only a few miles from the University. The project means the building up in the neighbourhood of Halifax and Dartmouth of a strong centre for marine sciences. It will include the Atlantic and sub-Arctic sections of the Canadian Hydrographic Service, the oceanographers, hydrographers and geologists who work in the Arctic and the Atlantic Oceanographical Group of the Fisheries Research Board. Ten new ships to serve them are already being planned and the first, the C.G.S. *Hudson*, costing seven million dollars, is expected to be commissioned in 1961. The main purpose of the new laboratory, which will be called the Bedford Institute of Oceanography, is to study the physics of the water and the sea bed, but provision is made for close co-operation and liaison among all aspects of the subject, and with the rapidly growing effort on the Pacific coast and work on the Great Lakes. In making the announcement the Ministry of Mines and Technical Surveys stressed the importance of a better understanding of the oceans to science, defence, commerce, and development of the country's resources.

Reconstruction of Brazilian Library

An appeal for help to reconstruct the library of the Brazilian Centre for Physics Research, damaged in a recent fire, has been launched by Unesco and the International Atomic Energy Agency. At a meeting of Unesco's Executive Board in Paris in June, Prof. P. de B. Carneiro stated that the Centre's collection of works on nuclear physics and higher mathematics, the only one of its kind in Latin America, has been almost entirely destroyed. The Executive Board responded to the appeal by recommending a number of measures to provide international aid from Unesco, the International Atomic Energy Agency and the U.N. Technical Assistance Administration. The library has been added to the list of projects for which Unesco gift coupons may be given. Universities, libraries, technical institutes, non-government organizations, and governments of Unesco's Member States have also been asked to contribute. Organizations or individuals wishing to help in the restoration of the library may write to Centro Brasileiro de Pesquisas Fisicas, 71 avenida Venceslas Braus, Rio de Janeiro, Brazil. All offers of books, micro-films, extracts or other documentation should be made directly to the Centre. Gifts of money may be sent in the form of Unesco Gift Coupons, about which information may be obtained from the Public Liaison Division, Unesco, Place de Fontenoy, Paris 7e.

Grants for U.K. Students

THE 1959 Grants Year Book, the fourth to be issued by the National Union of Students (1959 Grants Year Book. Local Education Authority Awards to Students. Pp. 107. London: National Union of Students, 1959. 2s. 6d.), comprises a detailed guide to the values of awards paid by the Ministry of Education and the Local Education Authorities to students taking courses of higher education and to the regulations governing those awards. These details are arranged by counties and county boroughs and there are appended notes on university and technical college awards, on training college awards, postgraduate awards of the Department of Scientific and Industrial Research, and other bodies. An account of the new system recently introduced in Northern Ireland is included, and there is a general survey of awards, 1958–59, based on information received since November 1958. An introduction to the Year Book urges the importance of further expansion of the teacher training colleges and stresses the need for a national scale of minor awards assessed on the same basis and principles as the major awards to eliminate the present wide variation in minor awards for technical and similar courses. Attention is directed to the wide variations between the local education authorities in number of awards shown by the Ministry of Education's published statistics.

Research in Dairying

IT is not often realized that the milk produced in the United Kingdom nowadays amounts to about 2,200 million gallons a year and is worth about £1 million a day. An industry of such magnitude and importance surely deserves a first-class research service. The fact that it has got such a service can be seen from the annual report of the National Institute for Research in Dairying for 1958 (pp. 154. Shinfield: National Institute for Research in Dairying, University of Reading, 1959. 4s.). It is clear from the report that the Institute is making a very thorough study of the scientific principles on which the art of dairying is based, by doing research work of a high quality on fundamental problems, such as digestion and metabolism in the ruminant, the biochemistry and physiology of milk secretion, and also on problems of an immediately practical nature such as those concerned with the growing of crops for feeding dairy cattle, the milking technique itself and many technical and engineering problems associated with the handling and processing of milk and the manufacture of milk products. The report contains an informative description of the work that is being done in each department of the Institute, and some of the more significant of the recent findings are summarized in a brief outline which gives information on about thirty of the many different items under investigation. A well-deserved tribute is paid to Prof. H. D. Kay, who retired last year after being director of the Institute for more than twenty-five years, and also to the Earl of Iveagh, who has resigned from the board after a long period of service in which he did so much for the welfare of the Institute and its staff. The report includes a detailed list of 182 papers that were published in the period under review.

Mathematical Games

AMONG the many aspects of Japanese culture that have recently engaged the interest of Americans is 'origami', the ancient Japanese art of paper-folding. Several books on the subject are now available in English, an origami workshop flourishes in Manhattan and the country's first paper-folding exhibit was open to the public at Cooper Union's Museum for the Arts of Decoration in New York (*Scientific American*, 201, No. 1, July 1959).

The origins of origami are lost in early Oriental history. Folded-paper birds appear as kimono decorations in eighteenth-century Japanese prints but the art is many centuries older in both China and Japan. At one time it was considered an accomplishment of refined Japanese ladies; now its chief practitioners seem to be geisha girls and Japanese children who learn it in school. During the past twenty years there has been a marked upsurge of interest in origami in Spain and South America. Traditionally, origami is the art of folding realistic animals, birds, fish and other objects from a single sheet of paper, without cutting, pasting or decorating. The attraction of origami lies in the extraordinary realism that can be obtained with nothing more than a square of paper and pair of deft hands. A sheet is folded along geometrical lines. Suddenly it is transformed into a delicate piece of miniature semi-abstract sculpture of considerable beauty.

In view of the geometrical aspect of paper-folding, it is not surprising that many mathematicians have been fascinated by this art. Lewis Carroll, for example, was an enthusiastic paper-folder. The literature of recreational mathematics includes many booklets and articles on folded-paper models, including those curious toys called flexagons. The folding of regular polygons, though not part of classic origami, is a challenging classroom exercise. The equilateral triangle, square, hexagon and octagon are quite easy to fold, but the pentagon offers special difficulties. Paper can also be folded to produce tangents that have as their envelope various low-order curves. The parabola is particularly easy to demonstrate. Closely related to this folding procedure an interesting problem in elementary calculus can be demonstrated. The most remarkable of all origami constructions is, however, the bird that flaps its wings. A number of origami animals have action features: a fish that opens its mouth, a frog that hops when its back is stroked, and so on.

International Combustion Symposium

THE report of the Seventh Symposium (International) on Combustion, the first of the International Combustion Symposia to be held outside the United States, has been published (Pp xxvi + 959 London Butterworths Scientific Publications, 1959 224*s*) It contains 124 original papers presented during August 29–September 3, 1958, at Oxford Few who have a serious interest in combustion will fail to profit from a study of its pages The largest of the eleven groups of papers concerns the chemistry of combustion reactions, and there are three important groups devoted respectively to deflagration, detonation and combustion in flowing systems Smaller sections are concerned with spectroscopy, ionization and turbulence in flames, the last containing particularly welcome contributions to a difficult and, until recently, neglected subject. The section on ignition and limits of inflammability attracted mainly papers on the former subject, while that on the interaction of flames with surfaces proves to be a repository for papers on a variety of loosely related topics The section on special fuels is disappointingly short and the final group of papers on instrumentation is characteristically miscellaneous

The editors and publishers are to be commended on at least two counts For the first time the volume appeared with a delay of little more than six months after the meetings Furthermore, there is for the first time a rational and almost complete record of the discussions One suggestion still remaining to be implemented is that the papers should be provided with a uniform type of summary or abstract Will the Eighth Symposium book display every virtue of its kind ? The present volume has not fallen far short of doing so

Computer Applications

THE report of the proceedings of the fifth annual Computer Applications Symposium, held in Chicago during October 29–30, 1958, has now been published (pp x + 153 Chicago, Ill · Armour Research Foundation of Illinois Institute of Technology, 1959 3 dollars) It covers the whole range of applications of computers and some two-thirds of the papers are concerned with data processing or computer organization, even though sometimes labelled as engineering and scientific, as, for example, the papers by R A Haertle on "Use of a Computer in the 'AC' Spark Plug Division of General Motors", and by E M Chastain and J C McCall on "Computer Sharing by a Group of Consulting Engineering Firms" At first reading it would appear that the United States is much ahead of Britain technically in dealing with data processing and large-scale scientific work, but perhaps it is in the attitude of mind towards application of the computer to this type of work that Britain is really behind The breadth of vision shown in papers such as that of Col Ellett, dealing with the data processing for air material command, and the willingness to attempt the 'blue skies' approach indicated both there and in the paper by R D Whisler on work at Johnson's Wax, is very impressive It contrasts markedly with the timid and hesitating steps being taken in Britain and is a measure of the confidence now felt in the United States in the capacity of computers to carry through data processing economically On the technical side, one or two papers are of particular interest, such as that of R W. Hamming on "Frontiers of Computer Technology", and that of W F Bauer on "The Future of Automatic Programming" On the whole, it is an interesting report, but not of special interest to the general scientific reader, except to demonstrate the very wide field over which computers are now applied

Guatemalan Flora

THE Flora of Guatemala is continued with a part devoted to a number of families of Gymnosperms and Monocotyledons, including the large Cyperaceae, Palmaceae, Araceae and Bromeliaceae (Chicago Natural History Museum Fieldiana Botany Vol 24, Part 1 Flora of Guatemala By Paul C Standley and Julian A. Steyermark Pp ix + 478 (121 figures) (Chicago, Ill Chicago Natural History Museum, 1958) 8 dollars) There is a number of helpful illustrations It must be remembered that this work also deals with the flowering plants (and their vernacular names) of British Honduras, "since on both geographic and botanical grounds it is essentially a part of Guatemala" This part opens with a plan of the Flora, and mentions certain areas of Guatemala which still need further exploration

Space Projectiles

THE Russian journal *Priroda* has recently published a series of articles dealing with various types of space projectiles launched in the Soviet Union and the type and methods of observations connected with these projectiles Thus Y L Alpert (10, 71 , 1958) discusses the study of the ionosphere, V I Krasovsky (12, 71 , 1958)—the study of the upper atmosphere, A E Chudakov (12, 88 , 1958)—the study of photons, N A Dobrotin (1, 57, 1959)—the study of cosmic rays, N S Yakhontova (4, 5 , 1959) presents an account of the small artificial planet launched in January, and, finally, V L Kurt (5, 74 , 1959) discusses the artificial luminous sodium comet

New Radioisotope Training Programme

THE Atomic Energy Commission of the United States has announced a new programme which will provide students of undergraduate colleges with the opportunity for specialized training in the techniques of using radioisotopes The new programme will utilize a mobile training laboratory which can be moved to the college campus for presentation of a short (two-week) concentrated course on the basic techniques of handling radioisotopes The laboratory will be similar to one presented last year to the International Atomic Energy Agency by the United States Further information is available from University Relations Division, Oak Ridge Institute of Nuclear Studies, P O Box 117, Oak Ridge, Tennessee

Animal Health Trust Awards, 1959–60

THE Animal Health Trust has announced the following senior awards for the period 1959–60 *Wellcome Fellowships* Mr P H Lamont to undertake investigation of enteroviruses of the pig, and their possible role, in disease, at the Department of Animal Pathology, Cambridge, under Prof W I Beveridge , Mr I R Falconer to study thyroid–ovarian–pituitary interrelationship at the Department of Biological Chemistry, University of Aberdeen, under Dr H A Robertson *Vitamealo Fellowship* This new award was founded to commemorate the 70th birthday of Lord Rank and his close association with Vitamins, Ltd , by whom it was given The first recipient is Mr D B Ross, who is to continue work on some of the more fundamental aspects of magnesium metabolism, particularly intestinal absorption Initially Mr Ross will work at the Department of Animal Pathology, Cambridge *Research Training Scholarship* Mr W A G Charleston to undertake an investigation into the mechanics of the quadrupedal vertebral column, with special reference to the dog and the cat, under Prof C W Ottway at the Department of Veterinary Anatomy, University of Bristol Eight Evans Final Year Scholarships have also been awarded

The International Nickel Company of Canada, Ltd., Fellowship

The establishment of a fellowship to honour the visit of H M the Queen and H R H Prince Philip, Duke of Edinburgh, to the nickel mines in the Sudbury area has been announced by the International Nickel Company of Canada, Ltd , and the Canada Council (the latter being a body established by the Canadian Government for the encouragement of the arts, humanities and social sciences) The fellowship will be called 'The Queen Elizabeth II Fellowship (The International Nickel Company of Canada, Limited, Royal Tour, 1959)' The award will be a postdoctoral fellowship tenable for two years Research can be undertaken in the chemistry or physics of metals, geophysics, geology, metallurgy, mineralogy, or mining Candidates must be Canadian citizens and holders of a doctor's degree and the fellowship must be held at a Canadian university The International Nickel Company has deposited 15,000 dollars with the Canada Council, which will supervise all arrangements for the fellowship

The Night Sky in November

Full Moon occurs on Nov 15d 09h 42m U T and New Moon on Nov 30d 08h 46m The following conjunctions with the Moon take place Nov 4d 16h , Saturn 5° S , Nov 27d 02h , Venus 0 6° N In addition to these conjunctions with the Moon, Mercury is in conjunction with Jupiter on Nov 7d 10h , Mercury being 3 4° S , Mercury with Antares on Nov 10d 05h , Mercury being 2 0° N , Jupiter with Antares on Nov 15d 16h , Jupiter being 5 2° N , Mercury with Jupiter on Nov 17d 06h , Mercury being 2 1° S , Mercury with Antares on Nov 17d 21h , Mercury being 3 3° N , and Venus with Spica on Nov 30d 05h , Venus being 4 5° N Mercury is too close to the Sun for observation Venus is a morning star, rising at 2h 35m , 2h 55m and 3h 25m on November 1 15 and 30, respectively , its stellar magnitude is −4 0 Its distance increases during the month from 55 to 77 million miles and the visible portion of the apparent disk increases from 0 443 to 0 598 Mars and Jupiter are too close to the Sun for observation Saturn sets about 2 hr after the Sun, and will be visible low in the southwest after sunset , conditions are not favourable for observation Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich Nov 4d 17h 47 6m , *Y* Sgr (*D*) , Nov 5d 17h 23 7m , ρ Sgr (*D*) , Nov 14d 3h 53 9m , ξ Ari (*D*) , Nov 16d 18h 32 0m , α Tau (*D*) , Nov 16d 19h 28 9m , α Tau (*R*) *D* and *R* refer to disappearance and reappearance, respectively The Taurid meteors are active during the first fortnight of the month, conditions being moderately favourable , the radiant is near R A 3h 36m , Dec + 14° The Leonids are active during November 15–17, but conditions are unfavourable for observation

Announcements

The first Polarographic Society Medal has been awarded to Prof J Heyrovský for his discovery of the polarographic method in the nineteen-twenties and for the subsequent major contributions to the subject by himself and his students

Dr W M Hampton, of Chance Brothers, Ltd , will deliver the Fifth Chance Memorial Lecture of the Society of Chemical Industry under the title "The Development of Furnaces for Glass Melting" The Lecture will be delivered on February 9 in Birmingham

Dr Ainsley Iggo, of the Department of Physiology, University of Edinburgh, has been appointed by the Royal Society to a Locke Research Fellowship Dr Iggo will continue his research at Edinburgh on unmyelinated afferent nerve fibres their peripheral specificity and their central connexions

Prof A L Hodgkin, Royal Society research professor in the University of Cambridge, and Prof R Milnes Walker, professor of surgery in the University of Bristol, have been appointed members of the Medical Research Council in succession to Prof R C Garry and Mr H J Seddon, who are retiring after their normal four-year term of service The Committee of Privy Council has also recently appointed Sir Hugh Linstead as the House of Commons member of the Council in succession to the late Richard Fort

The Bibliography of Scientific Publications of South and South-East Asia for June 1959 (No 6, Vol 5) compiled jointly by the Unesco Science Co-operation Offices for these areas and published by Insdoc, National Physical Laboratory, New Delhi, lists by subject a further 102 titles

The Committee on Fire Research and the Fire Research Conference of the Division of Engineering and Industrial Research of the U S National Academy of Sciences–National Research Council is planning a two-day international symposium on the theme "The Use of Models in Fire Research", to be held at the National Academy of Sciences in Washington, D C , during November 9–10 Further information can be obtained from Mr D W Thornhill, Executive Secretary, Committee on Fire Research and Fire Research Conference, National Academy of Sciences, 2101 Constitution Avenue, Washington 25, D C

Awards for study in statistics by persons whose primary field is not statistics but one of the physical, biological or social sciences to which statistics can be applied are offered by the Department of Statistics of the University of Chicago The awards range from 3,600 dollars to 5,000 dollars on a nine months basis or 4,400 dollars to 6,000 dollars on a basis of eleven months The closing date for application for the academic year 1960–61 is February 15, 1960 Further information can be obtained from the Department of Statistics, Eckhart Hall, University of Chicago, Chicago 37, Illinois

Erratum In the communication entitled "Incorporation of DL-[2-^{14}C] Mevalonic Acid Lactone into Polyisoprene", by R G O Kekwick, B L Archer *et al* , in *Nature* of July 25, on p 270, col 1, line 1, for "active" read "inactive"

THE NATIONAL PHYSICAL LABORATORY

THE National Physical Laboratory held two open days on May 27–28, when about 3,500 guests from industry, the universities and Government departments viewed 150 exhibits covering the main items of the current research programmes. As last year, the exhibits were chosen to illustrate certain selected topics, but arrangements were made for visitors to discuss with specialist members of the staff items of work not on display.

The nine scientific divisions of the Laboratory function largely as independent units, but in a number of cases the programmes involve close collaboration between divisions. This is particularly the case with the work of Mathematics Division, much of the work of which consists of providing advice and computing facilities to other divisions. Excellent examples of the fruitfulness of such collaboration were seen in the work on machine-tool control by the use of diffraction gratings, shown by the Light Division, and in a new infra-red spectrometer exhibited by the Basic Physics Division.

The measurement of fundamental standards has always been one of the basic responsibilities of the Laboratory, and a reorganization of Divisions in 1958 brought such measurements mainly within the fields of the Standards and Applied Physics Divisions, with the newly created Basic Physics Division concerned with more fundamental research in some newer fields.

In an experiment designed to measure the gyromagnetic ratio of the proton, apparatus for which was exhibited, the Standards Division is extending its field of endeavouring to relate measurement to atomic constants. A magnetic field about twenty times the strength of the Earth's field is produced by means of a known electric current in wire coils of known dimensions. At the centre of the coil system a spherical container is filled with water, the source of the protons. The latter are polarized in a direction perpendicular to the known field by a current maintained for a few seconds in a coil surrounding the sphere. When this polarizing field is removed the protons return to a state of equilibrium over a period of about 2 sec., during which time an e.m.f. is induced in the polarizing coil, now used as a pick-up coil. The frequency of this e.m.f., about 40 kc./s., is measured, and from it and the known applied field the gyromagnetic ratio is calculated. This constant is of importance for defining stronger magnetic fields, which may then be used for the determination of e/m for fundamental particles.

The tendency to relate all standards to more fundamental quantities is also seen in the use of monochromatic radiation as a fundamental standard of length. The precise intercomparison of wave-lengths has thus become of increased importance, and a high-resolution spectrometer for this purpose was shown. It uses the method of air-pressure variation to scan the fringes of a Fabry–Perot interferometer, but, since the instrument is illuminated with light of the two wave-lengths to be compared in very rapid alternation, it is not necessary to measure the absolute pressure of the air very exactly. In synchronism with the rotating 'chopper' shutter the output of the receiving photomultiplier is switched to two amplifiers. Errors due to changes of source intensity are eliminated by an additional photocell measuring the ratio of transmitted to incident light. The variation in intensity of the centre fringe with pressure for the two sources being compared is recorded on a chart recorder. Arrangements are also fitted for digitizing the records on punched tape, which can then be fed to a computer for Fourier analysis to obtain data on phase shifts at the semi-reflecting surfaces and other information. The instrument will be used for comparisons of standard wave-lengths, measurements of isotope shifts and work with sources at liquid-helium temperatures.

Another new field of standardization, undertaken in the Applied Physics Division, is that of neutron sources, required to produce known neutron fluxes for work in problems of reactor design. The strengths of the sources are compared by suspending them overnight by a fine thread at the centre of a large spherical container filled with manganese sulphate solution. A correction is applied for the neutrons escaping from the vessel. The amount of manganese-56 produced is determined by β-decay measurements, which are compared with those obtained after the addition of a known amount of active manganese to the same container. It is also hoped to obtain a confirmatory measurement from the amount of helium produced in three sources over a period of time. Six British sources have been compared with a Canadian standard.

The same Division has several rooms specially designed for the measurement of sound, but this is a field in which subjective measurements are of more than usual importance. The results of extensive experiments on the loudness of directional sound fields, as measured by pressure at the listener's ear, were shown. Such measurements, however, do not indicate the total loudness to a listener, owing to the additive effects of both ears. Charts were also shown for a group of observers, showing that the directional arrival for maximum loudness varies in a complicated way with frequency. An approximate binaural summation theory has been developed, from which some calculations of loudness have been made; these compare fairly well with the results of direct measurements.

The newer programmes in the Basic Physics Division are only now coming into operation. An interesting infra-red spectrometer of novel type, for study of the wave-length region 50μ–1 mm., was shown. This region is of particular importance in the theory of superconductors and of radiation from the Earth's atmosphere. A Michelson interferometer is used to scan the spectrum, the output intensity being received by a Golay cell. The resulting interferogram is then translated into a spectrum by digitizing the information and feeding to a computer. The instrument has considerable advantages over a conventional infra-red spectrometer in speed: in a typical example the range 100–300μ was observed in 25 min., with a resolution of 0·4 cm^{-1}, and computed in 5 min. It is hoped that with further development corresponding advantages in resolution will also be obtained.

The same Division also showed an ultrasonic goniometer In this device the critical angle of reflexion of an ultrasonic wave (5 mc /s) incident upon an area of about 1 cm^2 of the surface of the specimen is measured In metals of marked elastic anisotropy, any preferred orientation introduced during fabrication can be detected from the change in this critical angle It is, for example, in some cases possible to determine the rolling direction of a plate By varying the frequency of the incident wave (2–15 mc /s) some information on the depth of surface effects in texture can be obtained

In the Metallurgy Division results of importance in the fundamental theory of metals are being obtained from transmission electronmicrographs of thin iron foils Strip, 0 02 in thick and representative of bulk material, is thinned by electropolishing to 2–3000 A , at which thickness electrons can penetrate it The idea that in alpha iron two dislocations with <111> Burgers vectors unite to form one <100> dislocation with a saving of energy has been confirmed by the observation of a hexagonal network formed by the interaction of two dislocation systems Distortion in parts of this network, shown in some of the photographs exhibited, can also be explained in terms of the interaction of stranger dislocations Photographs were also shown of precipitates, about one hundred atoms thick, growing from a supersaturated alloy in dendritic form on dislocations

The recording of creep strain data is often a major item in the programme of a large metallurgical laboratory, and a new electrical recording extensometer, developed in the Division, promises to simplify this problem The movements of the extensometer are measured by the changes in inductance in a linear differential transformer fitted to the extensometer limbs The transducer is built into a bridge circuit, in which an electronic detector is used to determine the balance conditions, and measurements are independent of zero drift or changes in amplification Long-term stability, of great importance in tests lasting 10,000 hr or more, is dependent only on the stability of the transducer and resistors Other advantages of the equipment, the sensitivity of which is comparable with that of a mirror extensometer, are the possibility of measurements over a large range of strain without readjustment, and the application of automation to the recording of the data

Other Divisions of the Laboratory are concerned more with developments in applied science, with particular reference to problems of interest to industry, and Control Mechanisms and Electronics Division demonstrated a technique for the manufacture of radial coded plates for recording digitally the instantaneous position of a revolving shaft The individual code zones are generated circumferentially in succession, by optical reduction from a 35-mm film in conjunction with a dividing machine, and the precision of the latter is the limiting factor in the angular resolution obtained This process is much quicker, particularly for complicated code systems, than earlier methods of programming a set of events, for example, lamp flashes, to produce one element of all the code zones simultaneously in a radial direction An example was shown of an eighteen-code system with a resolution of 0 01° and a total radial width of 0 1 in

An application of radial diffraction gratings was shown in a system for measuring the torque in a rotating shaft Each end carried a radial grating in conjunction with a similar stationary grating, producing an alternating signal by interruption of an optical beam Any torque on the shaft is manifested as a phase difference between the signals from the two ends , such a system is sensitive to a few seconds of arc

In addition to the work on the use of diffraction gratings in machine-tool control, several novel uses of the interferometric principle were exhibited by the Light Division, a Kosters prism being used as a compact Michelson interferometer When used to measure the angle of tilt of a reflecting surface by the alignment of white light fringes such a system is sensitive to 1/10 sec of arc The instrument, with both coarse and fine adjustments to facilitate setting, has possible applications in engineering metrology The Kosters prism is also used as a reverse shearing interferometer for testing the revolution symmetry and asphericity of large mirrors In another method, in which no test plate or comparison system is needed, such larger systems are examined by the superposition of the scattered light from two identical plastic scattering screens The interference colours seen on the mirror indicate directly to a millionth of an inch how far each point of the surface is above or below that of an imaginary perfect sphere

The work of the Aerodynamics and Ship Divisions is from the nature of their subjects rather more specialized than that of other divisions Perhaps the field of greatest topical interest on display in Aerodynamics Division was that concerned with the new aerodynamic problems that occur in hypersonic flow (that is, at speeds greater than about five times that of sound), particularly those associated with the temperature of several thousand degrees centigrade that arise from aerodynamic heating The Division is developing a shock tunnel, in which the flow duration is about a millisecond, and a ‘hotshot’, in which about twenty times this flow duration can be obtained Two small shock tubes were shown in which spectrographic and microwave techniques are being developed for temperature measurements and for studying the effects of dissociation and ionization

Also of current interest is the design of slender wings, the planform and section shape of which combine to give the required low drag at cruising speeds of about twice the speed of sound, together with satisfactory stability characteristics and good landing and take-off performance Vortex-type flow separations from sharp edges are being studied in transonic

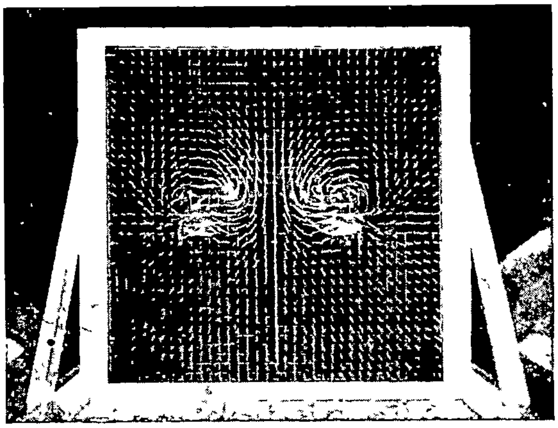

Fig 1 Vortex wake behind a swept-back wing at low speeds as shown by a tuft grid placed behind the model

and supersonic flow, and appear to behave in a remarkably similar way to those at low speeds (Fig 1) The work shown included detailed quantitative explorations in a low-speed tunnel and flow visualization experiments on a wing oscillating in a water tunnel in which qualitative observations were being made on the flow in these dynamic conditions

Results were also displayed from an extensive series of investigations into the aerodynamic design of swept wings for aircraft to cruise in the Mach number range 0 8–1 2 A special design of wing section has been developed to delay the drag rise that occurs at transonic speeds, and methods of combining a high drag-rise Mach number with a large drag-rise/buffet margin are being sought To enable drag-rise and buffet boundaries to be predicted, a semi-empirical theory has been developed for calculating pressure distributions in two-dimensional transonic flow The effects of wing planform, camber and twist have also been studied, together with the design of the junction between wing and fuselage, with the object of maintaining the full sweep of the isobars over the whole of the wing span One of the biggest problems is to reduce the required body 'waisting' to an amount acceptable for civil aircraft

Research displayed on boundary-layer and shear flows included theoretical and experimental investigations into the mechanics of transition following the non-linear growth of small disturbances, measurements of surface friction, and studies of turbulent boundary-layer development, wall jets, pipe flow, and the flow up an abrupt step at a Mach number of 2 5

As part of a long-term programme of research into ship vibration, the Ship Division demonstrated apparatus for determining the characteristics of the oscillatory pressure distribution around model propellers A large dynamometer for propellers up to 24 in in diameter measures torque and thrust electrically by movement of a balanced armature transformer, connected to a bearing in a helical slot on the shaft in one case, and to a flexible coupling allowing only axial movement in the other A new 12-in open dynamometer was also displayed this has a capacity of 5 lb /ft torque and 50 lb thrust at 0 to 2,000 r p m , torque being measured by balancing the reaction on the motor casing, and thrust by balancing the axial load on the shaft Both components are measured by dead-weight and spring systems, recording on a built-in chart recorder

On the Lithgow water tunnel, techniques for automatic data recording and analysis have been installed Measurements of the physical quantities are converted into either rotation of a shaft or into voltages shaft digitizers or digital voltmeters then turn these into coded electrical pulses suitable for feeding to computers

THE BRITISH GLASS INDUSTRY RESEARCH ASSOCIATION

NEW LABORATORIES

THE official opening of the newly built laboratories of the British Glass Industry Research Association by the Right Hon the Earl of Halifax, chancellor of the University of Sheffield, which took place on June 6, marked a noteworthy stage in the development of industrial research for the British glass industry Co-operative research has been continuously expanding since the inauguration by W E S Turner of a Department of Glass Manufacture in the University of Sheffield in the autumn of 1915 Prof Turner, then a lecturer in chemistry in the University, pioneered the establishment of a centre of organized scientific research into the physical and chemical properties of glass, to provide technical and scientific advice to the industry, and to include facilities for teaching Under his influence and professorship (he occupied the chair from its inauguration in 1920 until his retirement in 1945) the Department of Glass Technology, as it was renamed, became known and respected throughout the world by those interested in the manufacture and use of glass

In his early endeavour to found the Department of Glass Manufacture, Turner received great encouragement from his professor, the late W P Wynne, who loaned him a small chemical laboratory for his investigations and a tiny attic to house his glass-melting furnace He also received the enthusiastic support of glass manufacturers—particularly those of south Yorkshire and of Lancashire With increase of work and staff, Turner expanded his Department to occupy first a section of the applied science building of the University, and when this became insufficient, the site of a derelict glassworks in the Attercliffe district of the city The latter site was occupied until 1938 when, with the financial support of the glass industry, the present Department was built by addition to a large house occupying extensive grounds adjoining the main University territory

After the Second World War it became apparent that the requirements of industrial investigations, and that part of the research work which formed their immediate background, involved so much time that staff could not efficiently conduct them coincidentally with teaching and long-term research duties Prof H Moore, who succeeded Prof Turner on his retirement in 1945, therefore advocated the establishment of a research association as a separate entity, the function of which would be to attack the industrial and development problems, leaving the University Department free to concentrate upon fundamental research and the education of glass technologists On the retirement of Prof Moore in 1955 this plan was adopted, Prof R W Douglas being appointed to the chair of glass technology, and Dr R G Newton as director of the newly formed Research Association From this time until the occupation of its new building in January 1959, the Research Association's staff was successfully accommodated in the University Department's building, despite the rapid expansion of both organizations The foregoing will have indicated the close connexion between the University, the Research Association and the glass industry , the new buildings of the Research Association, built to the design of Prof Stephen Welsh, now stand adjacent to the University Department, which will enable the close connexions of the past to be maintained in the future

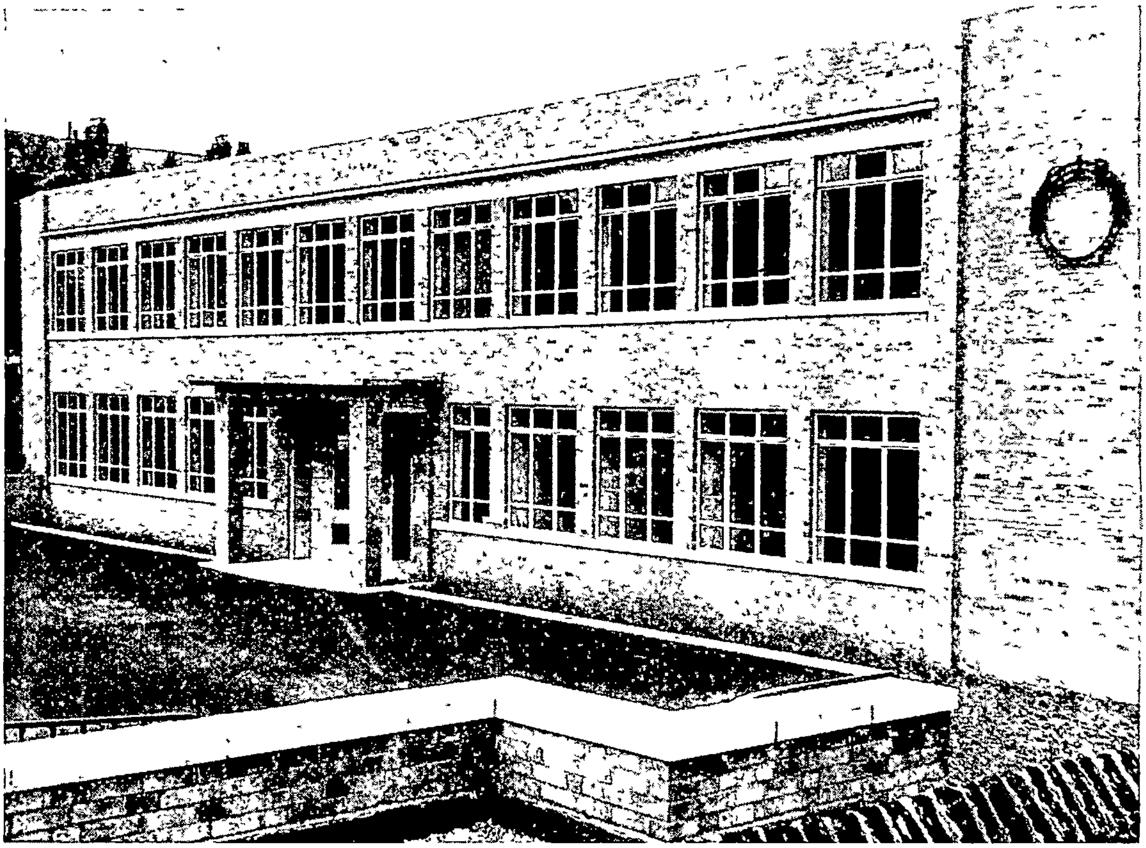

Fig. 1. The British Glass Industry Research Association Laboratories

The British Glass Industry Research Association is supported by eighty-nine subscribing member firms, forty-seven of which are engaged in glass melting, the remainder being closely associated with glass manufacture through the supply of raw materials or are connected with the manipulation of fabricated glass, as, for example, the formation of articles from glass tubing. The strong backing of the British Glass Industry Research Association by industry is denoted not only by the fact that approximately half its income is derived from members' subscriptions but also from the fact that the forty-seven members previously noted as being concerned with the actual melting of glass together melt 98 per cent of the total glass melted in the United Kingdom. Strong financial support is also provided to the Association by the Department of Scientific and Industrial Research.

Following the opening ceremony, members and guests of the Association were invited to tour the new building and inspect numerous exhibits which illustrated the type of work being carried out by the Research Association. The laboratories are sectionalized to conform so far as possible with the type of problem to be dealt with. The two-story building, which has a total superficial area of 20,000 sq. ft., is of 'L'-shaped plan, the ground-floor housing administrative offices, a section dealing with fuel, furnace and instrumentation problems, laboratories for the study of glass technological problems, a refractories section, and a furnace room with its associated batch mixing shop. The furnace room is sited at the extreme end of the wing and occupies a single story only so that heat and noise will not impede the work of other sections. The first floor is occupied by a reference library and information section, with associated reading rooms and meeting room, work study section, drawing office, and with the physical and chemical laboratories. Each of the latter two sections is subdivided into main and subsidiary laboratories. In the chemical section, for example, a separate division has been made to enable the durability of glass to various attacking media to be studied without the influence of the general atmosphere of the main chemical laboratory. Muffles and lead-lined fume cupboards for decomposition with hydrofluoric acid have also been segregated, and a separate division for spectrographic work has been provided.

A semi-basement extending beneath approximately half the ground-floor area contains an excellently equipped workshop, a pot room and a pot drying-room for the manufacture of small melting pots and other refractory articles. The remainder of the basement area is given to storage space, boiler-house, and a glass grinding, cutting and polishing unit.

Numerous demonstrations illustrating the type of work done by individual sections were presented, of which only a limited number may be mentioned within the compass of this short review. The fuel, furnace and instrumentation section demonstrated methods of surface temperature measurement and the estimating and recording of oxygen content of waste gas from furnaces, together with results of furnace heat surveys carried out at member-firms' factories with the view of assessing furnace performance under varying conditions. The physics section demonstrated laboratory apparatus for the determmination of tensile strength and thermal expansion, the latter by instrumental recording of the rate of expansion, thus eliminating the necessity for lengthy periods of direct observation. This section also demonstrated a pressure test rig for glass panels in which deflexions from fifty individual points on the glass surface were simultaneously displayed on scale instruments and cine-photographed at second intervals during the loading cycle. The performance of different types of refractory materials for glass furnace construction had been the subject of investigation by the refractories section, and a demonstration of a corrosion–erosion test rig was given. The glass technology section showed a novel rotating hearth furnace designed to give identical thermal treatment simultaneously to a number of experimental glass batch mixtures. This apparatus is to be used for study of the influence of raw materials on the rate of founding of glass. The chemical section, in addition to numerous examples of analytical techniques in silicate analysis, demonstrated apparatus for the determination of the durability of glass to aqueous attack, and gave an excellent demonstration of the analysis of gaseous inclusions in glass. The demonstration showed methods of extraction of minute bubbles of gas from solid glass and of their analysis to the component gases carbon dioxide, carbon monoxide, sulphur dioxide, sulphur trioxide and oxygen. Such studies have an important bearing on the problem of melting high-quality glass at maximum rate. The work-study section illustrated the use of one-second interval cine-photography for the study of manual operators in factories, and has shown that this technique can prove of value when a number of individual manual operations have to be co-ordinated with each other or with the operation of a machine.

Speakers at the official luncheon marking the opening ceremony reviewed the origin and future objectives of the British Glass Industry Research Association. Dr. L. H. A. Pilkington, chairman of the Council of the Association, directed attention to the man-power deployed on research in glass technology at the present time, estimating this to be some 200–250, and forecasting that the figure would increase to 750–900 within a five-year period. Although smaller in numbers than a force of some 750 at present employed in research by four of the largest glass manufacturing firms of the United States, these men managed to keep us abreast of developments in many fields and definitely ahead in some. Mr. A. W. Clark, chairman of the Glass Manufacturers' Federation, referred to the value of research associations to smaller firms the resources of which could not justify individual research units.

COIL SPRING FEDERATION RESEARCH ORGANISATION

NEW LABORATORIES

THE Coil Spring Federation Research Organisation, which has been in existence for fourteen years, has for the majority of this time confined its research activities to extra-mural work in universities, although the long-term aim of the spring industry has always been to operate its own research and development laboratories while maintaining the close links it has established with universities. This has now been achieved by the setting up of a new research centre, the construction of which has been financed from reserves set aside for the purpose.

The two-story laboratory block recently completed in Doncaster Street, Sheffield, is probably the most comprehensive of its kind for research into all forms of springs and spring materials.

The ground floor, in addition to the usual reception facilities, contains laboratories for heavy-fatigue testing, general mechanical testing, experimental heat treatment and electroplating. In the fatigue testing laboratory are housed 12½ h.p. machines capable of applying a dynamic load of 9 tons, which are used for fatigue testing heavy coil springs; up to eighteen springs may be tested at one time. Other machines used for fatigue testing springs of the internal combustion engine type are capable of infinitely variable speeds of compression of up to 4,000 per min. Fatigue tests in repeated torsion are carried out on torsion bars, and are used to produce data from which an assessment of the effects of composition, heat treatment and surface condition can be made prior to the manufacture of experimental helical springs. A special feature of this laboratory is the sound-proofing and anti-vibration features incorporated in both the suspended ceiling and the floor.

The mechanical testing laboratory houses a variety of conventional machines used for determining the properties of both specimens and springs, covering the range of material diameters 0·004–2·0 in. One machine, for example, is capable of developing a maximum torque of 120,000 in. lb., and is used to investigate the effects of hardenability on the static torsional properties of large-diameter spring steel bars.

Many researches relate to the load-deflexion characteristics of springs and the Organisation has a comprehensive range of machines, capable of applying static loads from a few ounces up to 30 tons. The determination of fatigue characteristics of drawn wires of diameters 0·01–0·25 in. is provided for by high-speed rotating-beam fatigue machines, which can complete up to 100 million cycles in as little time as one week. The study of corrosion and protection of spring materials and the effects of hydrogen embrittlement due to electroplating has had an important place in the Organisation's programme for many years. The work is being continued in a new laboratory specially fitted out for this purpose; the plant in it has been presented by Messrs. Canning, Ltd., the Birmingham manufacturers of electroplating equipment. Facilities are available for electroplating copper, zinc, tin, cadmium and nickel. The experimental heat-treatment laboratory is equipped with fully instrumented electric furnaces for general heat treatment, and high-temperature heat treatment under various types of protective atmosphere.

The laboratories contain a number of machine tools and a shot-peening unit which automatically rotates the object under treatment while at the same time traversing it with the shot stream It is being used in a fundamental study of the effects of shot-peening and optimization of it, together with an assessment of possible methods of measuring intensity

The first floor is devoted to light laboratories (containing small static testing machines, general scientific instruments and equipment), administrative offices, and a conference room The materials testing laboratory contains machines for determining macro-hardness, tensile and torsional properties of wires and load-deflexion characteristics of small springs Metallographic facilities are provided in specially fitted rooms for rough sample preparation, fine polishing and etching, microscopical examination and photography The microscope room contains a high-powered binocular bench microscope, projection microscope and micro-hardness testing equipment

The Organisation is studying spring materials for elevated temperature applications, in particular the stress-temperature relaxation properties of springs made from a very wide range of alloys A battery of spring creep testing machines is installed which will enable the behaviour of springs to be determined up to 850° C

CHEMISTRY OF PROPELLANTS

A MEETING was recently held in Paris (June 8–12) under the auspices of the Combustion and Propulsion Panel of the Advisory Group for Aeronautical Research and Development, with "Chemistry of Propellants" as the main topic It was felt that such a meeting could contribute to a useful exchange of research information and discussion of current problems among North Atlantic Treaty Organization countries Its importance can be judged by the attendance of nearly two hundred observers from eleven countries, nominated through their Advisory Group for Aeronautical Research and Development national delegates

The meeting was opened by Dr von Karman, who was supported by Dr Seitz, the science adviser to the North Atlantic Council, and his recent predecessor, Dr N F Ramsey Later in the week Dr G B Kistiakowsky, the new scientific adviser to the President of the United States, attended and took part in the proceedings These could be classified under three main headings, namely, propellants or associated features for liquid rockets, solid rockets and air-breathing engines, and the papers presented covered reviews of existing knowledge, reports of recent work and assessments of future problems

The first technical session was introduced by a paper by S Greenfield (United States), who reported on an experimental evaluation of liquid-propellant data This was based on a research programme to compare differences in behaviour of various hydrocarbon fuels when burned with liquid oxygen The fuels were pure samples of each of the chemical types such as paraffins, aromatics and olefins together with a reference fuel specified as *JP–5* The main results covered liquid film heat transfer coefficients and their variation with heat flux and combustion stability, specific impulse variations with mixture ratio, and effect of aromatics on available energy in fuel-rich gases suitable for turbo-pump operation An interesting feature of this work was the precise measurements achieved and the important influence of combustion chamber length (or L^*) on performance The conclusion was drawn that naphthenics are beneficial in a mixed fuel, but normal paraffins are of doubtful value

This paper was, to some extent, complementary to another by R J Thompson (United States) covering theoretical performance evaluation This work was carried out on an electronic data-processing machine and presented a vast tabulation of thermodynamic functions and propellant parameters which were discussed and illustrated The main propellant combination discussed was liquid oxygen and kerosene, although data on fluorine-liquid hydrogen were also used to illustrate the calculations Additionally, thermodynamic properties as functions of temperature for eleven of the more important elementary monatomic gases were given It is certain that these two papers will be of great use in future studies of propellants

The next paper in this group was by D L Armstrong (United States) and reviewed the characteristics of liquid propellants desired and achieved in rocket engines The important physical properties included vapour pressure, density, viscosity, specific heat, boiling and freezing points, and other features which were tabulated and discussed Chemical properties were also enumerated and mention was made of reactivity, self-ignition, combustion kinetics, stability and corrosion The author also gave some indication of performance, manufacturing processes and suggested propellants for various missions, but much more detailed and relevant papers on these aspects were presented by W G Parker and G Ruston (Great Britain) on the merits of utilizing high-energy propellants, and S H Dole and M A Margolis (United States) on the sources, availability and estimated cost of propellants The former took a slightly unusual line in dismissing the majority of the exotic propellants from consideration, first, because of the unfavourable properties such as extreme reactivity and toxicity, and secondly, because the advantages of higher specific impulse become less marked beyond values of about 320 sec Their conclusions were that liquid hydrogen was worth developing because of its probable use in nuclear rockets but it should be in combination with nitric acid or hydrogen peroxide rather than liquid oxygen The accidental combination of hydrogen and oxygen liquid or vapour could be too great a hazard to risk The paper on costs pointed out that prices of many propellants would be significantly altered if production demands increased, but even allowing for this, it was clear that the cryogenics would give a better performance than the storable liquids for a given cost Costs should, however, include the overall system cost and some curves were given showing flight vehicle cost against total impulse required for solid propellant storable and cryogenic At the higher values of total impulse, the cost of using these propellants was in descending order This was strongly challenged by protagonists of solid propellants during the discussion

The papers on solid propellants were given by R Steinberger (United States) on the properties o double-base forms with a corresponding one by P Tavernier and J Boisson (France) on composite forms and one on burning rate control by G H Young (Great Britain) All these appeared to suffer from the limitations imposed by 'security', but the first two gave useful accounts of the standard materials and processes in manufacture It was interesting to compare these and from this point of view they were an informative contribution Steinberger, however, included a good deal more on the life expectancy of double-base propellants This is not surprising in view of the much longer experience of them which exists The paper by Young covered some of the same ground and, rather than a discussion of burning rate control, was limited to descriptions of methods of measuring burning rate and the range of burning rates achieved The difficulties imposed on this author by the classified nature of his subject were obvious and it was generally agreed that it could only receive suitable treatment at a closed session

The papers on air-burning fuels included one on properties and preparation of ramjet fuels by M Barrere and G Français (France), one on performance evaluation by E Perchonok (United States), one on deposits in jet engines by R Breitwieser (United States) and a final one on physicochemical reactions during nozzle flow by J F Morris (United States) The first two covered the main features found necessary in the special conditions of ramjet operation and collected much data which will be useful for future reference Both papers dwelt on the use of solid fuels in slurry form and the attractions of boron hydrides and other compounds, but the American paper emphasized some additional considerations if ramjets are to be operated at hypersonic speeds For example, the need for regenerative cooling of engine walls will limit the use of *JP*–4 fuel to speeds of $M=6$ The high gas temperatures resulting from these speeds also have an important effect on dissociation conditions and thrust available With frozen gas exit flow, the thrust may be reduced as much as 58 per cent at $M=8$, compared with equilibrium flow This problem was treated by Morris, who reviewed the background of relaxation rate-theory and discussed the gaps in knowledge which will enable predictions of non-equilibrium flow of both internal and external gas for hypersonic vehicles The long list of references appended to this paper calls for special mention as it extends to more than four hundred The other paper in this group emphasized the problems of solid deposits in engines and pointed out that these became more serious with some of the high-energy fuels now being considered Boric oxide is one combustion product which may form on engine surfaces in large quantities Some measurements on convergent–divergent nozzles showed losses in total stream momentum of more than 5 per cent within 20 sec of initiating combustion Other sensitive components are turbine stator blades and combustion chambers Two mechanisms of deposition were discussed, consisting of diffusion of particles less than $\frac{1}{2}\mu$ diameter, and of impact by particles of 5μ and larger The former was analysed theoretically and compared with measured deposition rates Although good agreement was claimed, this analysis received some criticism during the discussion

In addition to the papers, a round table discussion on basic problems in propulsion was held with Dr von Karman in the chair The discussion was initiated by A D Baxter (Great Britain), who summarized the merits of liquid propellant rocket engines and outlined some of the remaining lines which require research These included physical problems such as heat transfer and combustion chamber design parameters, and chemical problems associated with propellant stability, ignition delays and reaction rates H W Ritchey (United States) then presented a similar case for solid propellants and was followed by three speakers giving views on futuristic possibilities G B Kistiakowsky (United States) spoke on solid propellant horizons, J W Bond (United States) on electromagnetic and nuclear thermal propulsion, and A Ferri (United States) on composite launchers The last was a stimulating argument in favour of air breathing engines as the first stage in multi-stage rocket vehicles One of the advantages would be the ability to fit aerodynamic lifting surfaces and fly the launcher back to the take-off point The discussion was so successful that it was continued at the final session of the meeting, ranging over a broad field Points brought out were the convergence of design features in solid- and liquid-propellant engines, the question as to how vital improved specific impulse was, the problems of size in rockets and the future of nuclear rockets

This discussion was a fitting climax to a successful meeting and no doubt, when the edited proceedings are published, they will be found to provide a valuable addition to the literature, not only because of the data included, but equally because of the excellent bibliographies attached to most papers A D Baxter

CLAY MINERALS

TWO series of meetings on clay minerals were held in Yorkshire during April The first, at Sheffield, was arranged by the Clay Minerals Group of the Mineralogical Society Two sessions on April 15, in the Metallurgy Department of the University, were devoted to the reading of scientific papers, while on April 16 visits were made to the works of Thomas Marshall at Loxley and General Refractories at Wharncliffe The chair at the scientific sessions was occupied by Dr A F Hallimond (London), chairman of the Group, in the morning, and by Prof J White (Sheffield) in the afternoon

Several papers concerned the industrial application of clay mineralogy In the first of these, E H Steger (London) discussed various problems in civil engineering in which clays are implicated, and dealt particularly with soil stabilization by injection of a suitable clay suspension into sands, etc The factors necessary to give good results are broadly known, but much work on fundamental aspects is still required In the discussion, the difficulty of replicating laboratory findings in the field was widely referred to

Divergent views upon the relationship between the mineralogical constitution and the firing properties of clays were expressed by Prof G W Brindley and S Udagawa (Pennsylvania) and by Dr R W Nurse (Watford) The former described how, by 'synthesizing' clays from mixtures of appropriate pure minerals over a range of compositions, it is possible to make some forecasts regarding the behaviour of natural clays from a rapid check of their mineralogical composition This technique enables immediate rejection of completely unsuitable clays, but those which appear of possible use still have to be tested individually Dr Nurse, on the other hand, could find no correlation between firing properties and mineralogical composition for a series of clays of various geological ages

The use of thermal expansion measurements in indicating the mineralogy of clays[1] was considered by D A Holdridge (Stoke-on-Trent), who showed its application in quartz determinations The significance of the same test after firing was also discussed

Dr R F Youell (Leeds) described how X-ray data on heat-treated silicates, which he had obtained earlier, were explicable on the basis of silicon-containing spinel structures[2] He particularly referred to the composition of the spinel phases and the occurrence of ordered transformations In discussion, the propriety of using the term 'silicate' for a silicon-containing spinel was questioned and the frequency of occurrence of ordered transformations was stressed

Three general papers were also read In the first B D Mitchell and Dr R C Mackenzie (Aberdeen) described a relatively inexpensive controlled-atmosphere differential thermal analysis apparatus and illustrated its applicability to investigations in nitrogen, oxygen and steam, while in the other two Dr H G Midgley (Watford)—this paper was read in his absence by Dr R W Nurse—and W Windle and E K Cundy (St Austell) described occurrences of sepiolite and zinnwaldite, respectively, in Cornwall, chemical, X-ray and other data were given

This meeting not only brought to notice relatively new uses of clays in industry (such as their use in soil stabilization) but also raised the practical question of the value of mineralogical analysis in assessing clays Difficulties encountered in relating the mineralogy of a clay to its firing properties could, for example, be due either to incomplete mineralogical data or to effects being not truly additive the observations reported rather suggest the latter

The Sheffield meeting was followed by one at Leeds during April 17–18 arranged by the X-ray analysis Group of the Institute of Physics This meeting included a session on clay minerals as well as one on biological fibres, only the former is reported here

No outstanding advance in structural investigations of the common natural clay minerals was forthcoming at the meeting Prof G W Brindley, in an introductory address, pointed to the value of electron diffraction techniques in such investigations He was able to report a very promising approach to the problem of thermal changes in kaolinite by his collaborator, M Nakahira, using small single crystals This work suggests that the 'spinel' phase is really a silica–alumina crystallization structurally similar to spinel[2], and appears to have furnished clear evidence that the much-discussed metakaolin is not amorphous, but is an intermediate stage in the formation of spinel, having a substantial degree of crystallinity

The dehydration products of kaolinite were also discussed by F Vaughan (Stoke-on-Trent) D A Holdridge showed the possibilities of thermal expansion measurements for studying phase changes on firing Quartz content, notably, can be estimated by this means

Interesting structural studies on scarbroite were reported by Dr J Goodyear and Dr W J Duffin (Sheffield) and on iddingsite by G Brown and Dr I Stephen (Harpenden) H P Rooksby (Wembley) reported on further detailed work on iron and aluminium oxides

The question of surface structure in clays is one of fundamental importance, about which there is still much uncertainty An extensive, many-sided approach to this problem is being made by Prof J J Fripiat and collaborators in Belgium under the auspices of Institut National pour l'Études Agronomiques du Congo Belge Among the techniques under study are measurement of surface hydroxyl groups by exchange with heavy water vapour, and methylation and acetylation for determining acidic groups

Dr D M C MacEwan (Dundee) reported on an extensive series of calculations on diffraction effects from mixed-layer structures, now being carried out with electronic calculators The resulting curves will be published as a special monograph by the Spanish Consejo Superior de Investigaciones Cientificas

Study of a German 'fireclay mineral' by Prof A L Roberts and Dr W E Worrall (Leeds) provided further support for Schofield's theory of the existence of isomorphous substitution in kaolins

THE COUNCIL FOR SCIENTIFIC AND INDUSTRIAL RESEARCH

THE second report of the Council for Scientific and Industrial Research covers the year 1958 in which the Department's gross expenditure was £9,453,652, compared with £8,255,561 in the previous year, and reduced to £8,357,913 by various receipts (£464,713 being from the National Physical Laboratory) for work done for Government departments or for industry, the net increase on 1957 being £1,108,070 Grants to students amounted to £444,958, the number of students in training being 1,681 and in 1957, 1,301, of whom 781 in 1958 and 653 in 1957 were new The advanced course studentships increased from 152 in 1957 to 201, of which 184 were new, and of 26 research fellowships (18 in 1957), 14 were new Grants for special researches totalled £475,754, numbering 239 compared with £363,884 and 193 in 1957, and of these 147 were new Of these grants 106 were in physics, 45 in chemistry, 32 in biology and biochemistry, 24 in other engineering, 11 in geology, 7 in mathematics, 6 in chemical engineering and metallurgy, and 3 in electrical engineering Chemistry claimed 593 of research students, physics 360, biology and biochemistry 208, mathematics 144, chemical engineering and metallurgy 110, other engineering 100, geology 99, electrical engineering 50, and human sciences 17

Expenditure on the National Chemical Laboratory decreased slightly, from £160,404 in 1957 to £155,010, and there were also slight decreases in expenditure on fuel research (£330,502–£326,899) and fire research (£38,745–£37,174) , but with these exceptions expenditure increased on all branches of the Department's work, the biggest increases being in road research (£560,813 compared with £441,762 in 1957), the National Physical Laboratory (£737,958 compared with £638,031), headquarters administration (£377,905 compared with £307,436), mechanical engineering research (£507,104 compared with £454,810) and the Geological Survey and Museum (£328,329 compared with £282,370) Expenditure for other sections in 1958 was as follows, the 1957 figures being given in brackets building research, £541,371 (£521,065) , forest products research, £135,645 (£128,256) , hydraulics research, £100,650 (£91,967) , pest infestation, £89,369 (£83,341) , radio research, £159,398 (£135,657) , and water pollution research, £103,882 (£90,020) Besides the National Physical Laboratory, considerable payments for work done for other Government departments and industry were received in respect of fire research (£143,330), the National Chemical Laboratory (£104,715), the Geological Survey and Museum (£97,527), road research (£59,182), hydraulics research (£44,710), building research (£33,879) and mechanical engineering research Contributions to European nuclear research increased from £930,000 to £1,100,000, and of the grants for special researches authorized during the session October 1, 1957, to September 30, 1958, by far the largest is the £355,000 over four years from January 1, 1958, to Prof C C Butler of the Imperial College of Science and Technology for the construction of a large liquid-hydrogen bubble chamber

ROTHAMSTED EXPERIMENTAL STATION

REPORT FOR 1958

THE report of the Rothamsted Experimental Station for 1958* is a book of 283 pages containing accounts of the work of some twenty separate departments It follows the pattern of previous years in that it is introduced by a general report by the Director in which the more interesting departmental results are commented upon This is particularly valuable in that it enables the reader to appreciate something of the scope and cohesion of the Rothamsted work, and those who frame the Station policy are to be commended on the blend of science and practice that characterizes the research programmes Their reward is the use made of their results in the practical world of farming in Britain and overseas

The Chemistry Department has studied the action of organic matter in the soil, and popular conceptions of this may have to be somewhat modified in that in heavy soil, as at Rothamsted, its beneficial action appears to be derived solely from its nutrient content and no measurable effect from physical sources was found By contrast, in lighter soils organic matter is apparently necessary to maintain structure Work has continued on the main plant nutrients in soil and, in particular, attempts are being made to evolve a more accurate method of assessing available phosphate Soil analysts would welcome progress in this matter

The Physics Department has studied the electrical charges on clay, soil aeration, soil water, and the effect of crop rotation on soil structure This last experiment showed that using beet and carrots as the test crops, the effect from modification of structure due to rotation was largely confined to the period during, and immediately following, seed germination This again may surprise practical growers Studies in agricultural meteorology have continued and progress has been made with the analysis of temperature, humidity and ventilation data in spring wheat collected during the three summers 1955–57 A detailed survey is promised in a later report The mineralogical studies of the Pedology Department have been continued on native and foreign soils, and the results, as they accumulate, may well lead to a sounder basis for soil classification

Microbiological investigations have dealt with the decomposition of cellulose and some of the newer chemicals used in agriculture Many of these have proved to be subject to attack and therefore will be removed from the soil in time, a point of considerable practical importance Aspects of nodule formation on legumes have also received attention Although it has long been known that nitrate at the concentrations usually employed in nutritional work will depress nodulation, it was found that as little as 2 5 p p m of nitrate nitrogen would delay nodulation of white clover by two days A similar effect was given by nitrite but not by ammonium salts, asparagine, or urea, all of which are assimilated by the host plant at about the same rate

The Botany Department at Rothamsted has been interested for some time in the development and use of methods of growth analysis and these are now producing information on various aspects of crop growth Gibberellic acid was found to increase the yield of potatoes in the year under review This effect was only observed when nitrogen was high, and spraying actually reduced yields when this element was low Additional data suggest that the effectiveness of gibberellic acid depends also upon the time and frequency of application Weed studies reported upon include an evaluation of competition effects between crop and weed plants and the possible excretion of toxic substances by *Agropyron repens* No evidence of this was found in living material , the leachate from water cultures of this grass, in fact, actually increased the dry weight and leaf area of tomato and kale plants

The blackening of potatoes on boiling was the subject of a biochemical study that supported the belief that this discoloration is due to a complex of ferric iron and dihydroxy-phenols Boiling is believed to liberate ferrous iron, which combines with the dihydroxy-phenols in the potato to give relatively colourless ferrous complexes which blacken when oxidized in the air to ferric complexes Other work in this Department concerned mitochondria, the enzymic breakdown of chlorophyll in plant tissues and the properties, particularly the infectivity, of tobacco mosaic virus fragments

* Rothamsted Experimental Station Report for 1958 Pp 283 (Harpenden Rothamsted Experimental Station, 1959) 10s

Research in plant pathology covers a wide field. Progress has been made in devising staining methods for preparations of plant viruses for electron microscopy at high resolution. This is new work, but enough progress has been made to encourage the hope that the methods will contribute usefully to the further elucidation of particle structure. The increasing importance of cereal viruses in agriculture adds to their interest, and useful information on infectivity and host ranges has been obtained. Experiments on initial field establishment of potato blight (*Phytophthora infestans*) have shown that this may occur without the normal stem-infecting stage. It is likely, however, that infection from contaminated soil can only occur in a wet season such as 1958. Trials on the susceptibility to wilt (*Fusarium oxysporum f. pisi*) of pea varieties commonly grown in Britain have shown that resistance exists, but the parasite itself is so variable that the breeding of resistant varieties will not be easy.

The Nematology Department has conducted studies on the changes in eelworm populations under different rotations and individual crops. These together with concurrent observations on the movement of eelworms in soil and over plants should interest those concerned with the control of these pests in the field. Frit flies, gall midges, wheat bulb fly, slugs and earthworms are included in the wide range of animals studied by the Entomology Department. A short section deals with the ecology of the natural enemies of aphids. The Bee Department, as a result of improved methods of assay, has learned more of the nature and function of 'queen substance' produced in the mandibular glands of queen honey bees. It has been shown that 'queen substance' contains an inhibitor which, when fed to queen honey bees, can prevent them from queen rearing and which can also inhibit ovary development in queenless worker honey bees.

As a result of the disastrous epidemic of virus yellows of sugar beet in 1957, the staff of the Dunholme Field Station organized a survey of crops and issued spray warnings when needed. As a result, 100,000 acres were sprayed with very satisfactory results when compared with unsprayed areas in September. The value of spraying against aphids to check the spread of virus yellows is now firmly established.

This account has necessarily omitted much worthy of mention, but it is impossible, in a short review, to do justice to all the work described in this report and the selection of items for particular mention here is obviously open to criticism. The extremely useful list of publications for the year 1958, each with an abstract of the contents, with which the report closes, is a fitting indication of the value of Rothamsted to biology and agriculture alike.

J. H. WESTERN

AUSTRALIAN DEFENCE STANDARDS LABORATORIES REPORT, 1957

THE main sections of the annual report of the Australian Defence Standards Laboratories for the year ended June 30, 1957 (Pp. iv+60. Maribyrnong, Victoria: Defence Standards Laboratories, Department of Supply, 1959), are devoted to a statement of the functions of, and scope of work undertaken by, the Laboratories and descriptions of some of the more important projects and investigations carried out by the Divisions of Chemistry, Metallurgy and Physics.

In the Metallurgy Division work has continued on the production and investigation of chromium-base high-temperature alloys. The ultimate aim is to develop alloys suitable for use in gas turbines operating at rotor blade temperatures of 950° C. or higher. The plant for the production of pure chromium has operated satisfactorily and a total of 475 lb. of metal was produced during the year. It has been shown that ductile chromium can be made from suitably pure electrolytic chromium. Investigations included experiments on the tensile properties of annealed chromium, the influence of pre-strain on ductility, precipitation hardening effects and creep behaviour. A fractographic study, augmented by X-ray diffraction tests, was made of the cleavage surfaces in cast chromium. In addition, work has been done on titanium alloys; cathodic protection of ships and naval structures; and the mechanism of polishing and the nature of mechanically polished metal surfaces.

The activities of the Physics Division are discussed under the headings of chemical physics; radiological physics; the development and testing of electrical and electronic components for use by the armed services; and metrology. The study by the microwave interferometric technique of the propagation of detonation has been most fruitful. Radiation alarm systems and other safeguards against the mishandling of radioactive sources have been developed and work has continued on the determination of the energy and angular distributions of the radiation intensity in air at various distances from a point radioactive source. Facilities for the precise calibration of end standards of length have been improved, and standardizations of lengths up to 40 in. based on the wave-length of light can now be made. A technique has been developed for determining the mean diameters of capillary tubes by the mercury content method to an accuracy of 0.00004 in.

The Chemistry Division has been active in a variety of fields, including the determination of gases in metals and alloys; the microdetermination of silicon; infra-red spectroscopy; adsorption; and organic and polymer chemistry.

The annual report lists the various personnel of the Laboratories and their status, and gives details of the publications by members of the staff during the year under review. Papers were presented by members of the staff to the thirty-second meeting of the Australian and New Zealand Association for the Advancement of Science held at Dunedin during January 1957 and to the Institute of Physics Conference on Contemporary Optics in Sydney during September 1956. Noteworthy visitors to the Laboratories during the year were Sir Owen Wansbrough-Jones, chief scientist of the British Ministry of Supply, and Sir Leslie Martin, chairman of the Australian Defence Research and Development Policy Committee.

THE IMPERIAL CANCER RESEARCH FUND

THE fifty-sixth annual report of the Imperial Cancer Research Fund*, for 1957–58, describes the lines of investigation in progress in the laboratories at Mill Hill and Lincoln's Inn Fields They can be sub-divided as follows

(1) *Tumours induced by viruses*

Work continues on the virus ætiology of cancer by studying the mechanism whereby the virus gains access to the cell it infects, the virus's mode of replication and its specificity Attempts are being made to grow the mouse leukæmia-inducing virus in tissue cultures of embryo fibroblasts, and by reciprocal transplantation experiments to find "whether the cellular elements in such transplants survive or whether virus is liberated to produce a new tumour by infection of the host's own cells"

(2) *Tissue culture studies of tumour cells*

The reaction of tumour cells to environmental changes is being studied by observing the effect of variation in the tension of carbon dioxide on cells of the mouse sarcoma 37

"The activities of individual cells in culture of the various mouse tumours are being examined by time-lapse cinematography *BP*/8C and *BAS*/56 ascites tumour cells show 'tails' which may attach to the glass and which have great tensile strength and elasticity The undulating surface membranes of these cells show very active pinocytosis and unusually large volumes of culture medium may be injected in this way "

(3) *Preservation of tumours in the frozen state*

"The frozen tumour bank preserves tumours in an unaltered genetic state and these can therefore be used to check the respective inbred strains of mice for any genetic divergence which affects histocompatibility In this way it has been shown, with a strain *A* specific tumour, not only that A_2G mice are genetically distinct from true *A* but that the genetic change occurred prior to 1952 "

(4) *Heterotransplantation of human tumours*

Human sarcoma tissue is being maintained by subcutaneous, intramuscular or intraperitoneal transplantation in cortisone-treated hamsters, subcutaneously in cortisone-treated mice and in the anterior chamber of the eye in normal guinea pigs The attempts to grow human lung cancer in guinea pig anterior chamber or in organ cultures were unsuccessful, but 25 per cent of human embryonic lung tissue grafts survived 22–49 days in mice treated with cortisone

Other human embryonic tissues such as bone and bowel, some human adult tissue, for example, skin and transitional epithelium, and human prostatic carcinoma and adult rodent lung and prostate have all been maintained in fluid media "Organ cultures of mouse prostate have been employed to study the direct action of œstrogens and androgens on glands from mice of different ages The œstrogens produced epithelial atrophy and testosterone a stimulation "

(5) *Hormone-dependent breast cancer*

About 50 per cent of human breast cancers cease to proliferate if they are totally deprived of the hormones which control cell multiplication in the normal breast At present the operative technique of cutting off the supply of hormones is by the surgical removal of the ovaries, both adrenals and the pituitary This somewhat drastic treatment may give spectacular growth regression and clinical improvement, but unfortunately these have proved to be temporary

(6) *A pregnancy-dependent mouse tumour*

The spontaneous mammary tumour BR6 has the peculiarity of always first appearing during pregnancy and mostly regressing after parturition The tumour incidence is very high (in excess of 97 per cent in more than 400 mice that lived longer than six months, had more than two litters, and where the mothers had developed tumours) Under certain conditions some females not only remain tumour-free but give rise to tumour-free sub-lines which "   appear from transplantation experiments, to be genetically different from the tumour-prone line and one aspect of this genetic difference may be a greater androgen production by the males of the tumour-prone lines"

BEHAVIOUR OF SEA URCHINS

MANY of the habits of sea urchins were observed by A N Sinclair, during day and night diving in the waters around Sydney with members of the Underwater Research Group of New South Wales An aqualung and a waterproof torch were used (*Austral Mus Mag* , 13, No 1 , March 15, 1959)

When diving in daylight Sinclair was impressed by the numbers of the large, rough-spined sea urchin *Centrostephanus rodgersii* Many of these were seen in hollows carved in the sandstone rocks, and often the hollows were deep enough to contain the whole urchin, but were never as deep, comparatively, as the sharply etched hollows carved by the smaller urchins, *Heliocidaris erythrogramma* Other urchins appeared to be motionless, with the spines sticking out at right angles to the body surface in a typical 'hedgehog', or defence, position

It was found that after darkness set in the urchins became active Within an hour or two of sunset, numbers of *Centrostephanus* were seen 'out walking' on the rocks but they did not seem to favour walking on the sand The spines at such times were generally arranged in groups or cones If a torch was shone on the urchin for a short time no reaction to the light could be observed, but if the urchin was touched it immediately assumed the 'hedgehog' position seen in daylight

Results of marking specimens of *C rodgersii* in Clovelly Bay, Sydney, had shown that the urchins moved up to 3 or 4 ft from their rock holes within two hours of sunset and returned to their own holes by the next morning, though often each was lying turned round from its original position.

During daylight it was common to see vacant rock holes, which, by the absence of weed growth, appeared to have been recently vacated. Usually, however, these holes were again occupied within a week, but tagging techniques had been inadequate to reveal whether the occupants were the original ones or newcomers.

Unlike most of the finer-spined urchins, the slate pencil urchin, *Phyllasanthus parvispinus*, appeared not to live in holes, preferring crevices between rocks. In more than 200 sightings of these urchins, only one had been seen in a spherical rock hole. Most were in crevices, during daylight, but were so securely wedged in that they could only be moved by breaking spines. Other haunts of the slate pencil urchin were on the floor of forests of weed or kelp. Like *C. rodgersii* these urchins seemed to prefer deeper water and were more numerous in 20–30 ft. of water. Although each slate pencil urchin did not have its own particular rock hole, it returned to a particular locality.

The slate pencil urchins went out 'walking' at night, often covering 1 ft. in 20 min., and were seen attacking whelks bigger than themselves.

The commonest urchin at shallow levels within about 6 ft. of the surface was *Heliocidaris erythrogramma*. This was the dominant species, and practically the only urchin present in the intertidal zone. It lived in crevices and holes in the rock, which could be almost honeycombed. It appeared to dig holes much deeper in relation to its size than any other species. This urchin appeared in many colours: greens, reds, browns and purples, a new one being revealed at almost every dive. The spines were smooth and relatively short. One of the most interesting combinations of spine shape and colour in this urchin was in the blue or mauve specimens.

Tripneustes gratilla, a wanderer from tropic seas, apparently had the distinctive habit of being unconcerned with the need for shelter. It was usually found on the walls of caves or in the open many yards from the nearest shelter. It was a large-bodied urchin with very short white spines tipped red or mauve. The rounded body had a plain darkish colour, or was white with five darker major bands and five secondary bands. Some of these urchins carried small pieces of shell or weed, presumably for sheltering from the light. *T. gratilla* was usually seen at depths of 10 ft. or more.

Most of the useful observations made by diving were of an ecological, rather than a systematic, nature, and an observation ledge had been carefully watched at frequent intervals during the past seven months; however, other observation points will be established after a twelve months period has been completed. A handicap to observation was that many local residents had developed a taste for eating sea urchins and the colony risked extinction.

In summer the colony comprised: twenty *C. rodgersii*, one *H. tuberculata*, and one *P. parvispinus*. By early July the numbers of *C. rodgersii* had fallen to fourteen, and later in the month had been reduced to ten.

JOURNAL OF APPLIED POLYMER SCIENCE

THE study of polymeric systems originated largely from technological considerations, but has now grown into a scientific subject in its own right, with its own techniques and outlook. This change has occurred in a very short time, and its rate of growth can be illustrated by the increasing size of the *Journal of Polymer Science*, which attracts contributions from both chemists and physicists interested in the preparation and properties of these interesting materials. From the original *Polymer Bulletin*, published in 1945 with 158 pages, it has progressed stepwise: 1946–50, 598 to 800 pages; 1951–54, 1460 to 1,864 pages; 1955–57, 2,432 to 2,420 pages; 1958, 4,256 pages. This seven-fold increase in thirteen years shows no sign of slowing down, and the publishers have therefore decided, as a transition measure, to split the journal, the original journal to continue, but in addition to publish the *Journal of Applied Polymer Science**. The latter is intended to deal with the properties of industrially significant materials, leaving articles of a definitely basic character to the original *Journal*.

It is difficult to see how this distinction can be maintained. The first number of the *Journal* includes papers on such basic matters as thermal expansion and transition temperatures, impact strength and spherulite growth, and anisotropic properties of strained visco-elastic fluids. Perhaps a better grouping of subject-matter would be—preparative techniques; physical properties; characterization and constants; and applications.

The present tendency for publication of specialist journals, as distinct from the journals of learned societies of wider scope, must be taken as an inevitable consequence of increased specialization. Although it may facilitate the task of the scientist wishing to keep together papers on his own research subject, it has made it almost impossible for him to pay for the subscriptions. The stage has been reached where even the smaller scientific libraries cannot hope to purchase more than a small fraction of these specialist journals. This situation is likely to worsen, and the research man will have to visit large central libraries, or rely on abstracts to track down new papers of interest to him. Perhaps one solution is for the smaller libraries to pool some of their resources on a local basis, by arranging regular circulation through several laboratories. In any event one would like to see an extension of the system of reduced rates for personal copies. The increased cost cannot be blamed on the publisher; the cost per page has remained constant at 2.5 cents since 1952. The new *Journal* is somewhat larger in page size than the earlier publication, and this has improved the presentation and layout.

---

* *Journal of Applied Polymer Science*, Vol. 1, No. 1, January–February, 1959. Pp. 127. Published bi-monthly, covering two volumes annually. Subscription price, 17.50 dollars per volume. (New York and London: Interscience Publishers, Inc., 1959.)

MEASUREMENT OF COSMIC NOISE AT LOW FREQUENCIES ABOVE THE IONOSPHERE

By J P I TYAS, C A FRANKLIN and A R MOLOZZI
Defence Research Telecommunications Establishment, Ottawa

THE Canadian Defence Research Board, in co-operation with the National Aeronautics and Space Administration, is at present designing a 2–15 Mc /s swept-frequency ionosphere sounder to be launched as an Earth satellite by a United States vehicle The preliminary design objective calls for operation over a one-year period in an elliptical orbit with a perigee and apogee of 300 and 1,200 miles, respectively Power will be derived from the Sun via solar cells and nickel–cadmium rechargeable batteries

System studies have shown that cosmic noise is likely to be an important factor in determining the minimum sounding power for a satisfactory signal to noise ratio Published figures for cosmic noise at 3 Mc /s give brightness temperatures varying between 7×10^6 °K [1] and 120×10^6 °K [2,3] Measurements on the Earth's surface, particularly at such low frequencies, inevitably involve assumptions concerning transmission losses through the ionosphere, and for frequencies less than approximately 15 Mc /s the accuracy of existing data on cosmic noise is questionable[4,5]. A direct measurement of this noise using either a rocket or satellite is therefore indicated, and the results obtained would have the added merit of being of considerable interest in the field of radio astronomy

Ground-based radiometers have been described by several authors[6,7], and design techniques appropriate to the ground environment are by now well established By comparison, a radiometer for use in a sounding rocket or a satellite is severely limited in its dimensions, weight, and power consumption In addition, it must also survive the mechanical and thermal shocks associated with a rapid ascent through the Earth's atmosphere

It is found that the successful instrumentation of such a radiometer depends critically on the design of a suitable low-frequency aerial and reference noise source The use of one or more Hertzian dipoles, on a space vehicle, poses a formidable aerial calibration problem, which becomes increasingly serious as the frequency is reduced This approach was therefore abandoned in favour of the magnetic dipole, which is easier to calibrate since it is relatively unaffected by the proximity of the ground or other conducting surfaces

Optimum utilization of a given volume of ferrite has been investigated, and it is of interest to consider the design and efficiency of a pair of loop aerials at 3 Mc /s using 300 gm of ferrite

Two 18 cm × 3 cm × 1 cm rectangular cores, each made up of three plates of ferrite, were space wound so that each winding covered 80 per cent of the length of its ferrite core The calculated radiation resistance of each aerial was

$$4 \times 10^{-4}\ \Omega$$

and was found to be negligibly small compared with the equivalent series resistance due to core and copper losses

For a bandwidth of 80 kc /sec , and with the two aerials connected in series, the power available at the input terminals of the receiver is

$$4E^2 \times 10^{-16} \text{ watts}$$

where E is in μV /metre This power is 39 db below that available from a matched, loss-less, half-wave dipole

Transistor receivers with equivalent input noise temperatures of 600° K at 3 Mc /s have been constructed, and if the brightness temperature of the cosmic noise is 120×10^6 °K , the signal to noise ratio at the receiver output will be 11 db This includes an additional aerial loss of 3 db due to the random polarization of the noise

Errors due to changes in the gain and band-width of the receiver are reduced by continuously switching the receiver input between the aerials and a reference noise source At the output terminals of the receiver the ratio of the switched power-levels is

$$\frac{G(P_N + P_{N1})}{GP_{N2}} = \frac{P_N + P_{N1}}{P_{N2}}$$

and is independent of the receiver gain (P_N is the noise power from the aerials , P_{N1} is the equivalent input noise power due to the receiver when connected to the aerials , P_{N2} is the input noise power due to the receiver and reference noise source when the aerials are disconnected , and G is the power gain of the receiver) The addition of an A G C loop increases the dynamic range of the receiver to approximately 50 db and converts the output into a voltage suitable for telemetering to the ground If the A G C time constant is short compared with the period of rotation of the rocket or satellite, the existence of directional properties in the cosmic noise may be observed

The overall accuracy of the instrument depends largely on the stability of the reference noise-level and the accuracy with which the aerials can be calibrated on the ground An avalanche diode is used as a reference noise source and its case temperature is monitored on a separate telemetry channel Laboratory tests on this radiometer indicate an overall probable error of less than ± 2 db in the measured cosmic noise intensity

Errors due to atmospheric and man-made interference (including radiation from ground-based transmitters) will be negligible at frequencies less than the minimum penetration frequency of the F_2 layer Since the radiometer will be operating in an ionized medium, the electron density in its immediate vicinity will set a lower limit to the frequency at which cosmic noise can be measured In practice, this low-frequency cut-off will be modified by the Earth's magnetic field, and may also be higher than the local plasma frequency if regions of increased electron density exist above the radiometer At very high altitudes it is possible that the Van Allen belts may play a significant part in filtering out the low-frequency end of the cosmic noise spectrum.

A prototype radiometer is undergoing vehicle acceptance tests and the final instrument is expected to make the first measurements of cosmic noise above the ionosphere at 3 Mc /s in the near future

The sensitivity and accuracy of the radiometer could be improved by having a controllable noise source and using the receiver as a null detector, a technique widely used on the ground A silicon diode operating in the avalanche mode generates noise, the level of which can be controlled by varying the direct current flowing through the diode[8] Thus, one has a semiconductor analogue of a temperature-limited diode, and radiometers of the type described by Ryle[9] become practicable for space vehicles

The experiment will be extended at a later date to observe changes in the cosmic noise-level with frequency using a swept-frequency receiver By observing the wave-length at which the noise-level starts to increase rapidly, plasma frequencies, and therefore electron densities, can be deduced at various heights over different parts of the world from a satellite travelling in an elliptical orbit

SURFACE TOPOGRAPHY OF THE ANTARCTIC ICE SHEET

By Dr J F NYE
H H Wills Physics Laboratory, University of Bristol

IT has been reported by Lister and by Pratt[1,2] that the surface of the Antarctic ice sheet over much of the route of the Trans-Antarctic Expedition consists of a series of undulations with wave-lengths of 5–30 km and a mean amplitude of about 20 m In this respect the surface differs markedly from that of the Greenland ice sheet which, except near the margins is generally much more uniform[2,3] The question then arises as to whether the undulations seen in Antarctica are due to some effect of wind, which causes the snow to accumulate preferentially in certain places, or whether they are the result of unevenness in the rock bed upon which the ice sheet lies The following analysis leads to the conclusion that the latter explanation is the right one, and that we may hope to discover much about the topography of the bed simply by an inspection of the surface

Owing to the higher temperature of the lower layers of ice, and the large effect of temperature on the creep-rate of ice, the outward motion of the ice sheet probably takes place almost entirely by sliding on the rock bed (combined with rapid shearing in a very thin layer at the bottom)[4] The velocity of sliding u will depend on the shear stress τ at the interface, the effective roughness of the bed, and the temperature (and possibly on the hydrostatic pressure) At a given place on the bed let us assume that

$$u = \left(\frac{\tau}{A}\right)^m \tag{1}$$

where A and m are constants According to Weertman's calculation[5], which is appropriate where the ice in contact with the rock is at the pressure melting-point (which may be the case in parts of Antarctica), the value of m is 2 or 2 5 τ is given approximately[6] by $\rho g h \alpha$, where ρ is the mean density, h is the thickness, and α is the (small) slope of the upper surface averaged over a distance $\sim h$ Hence

$$u = \left(\frac{\rho g h \alpha}{A}\right)^m \tag{2}$$

u at a point is thus determined by the slope of the upper surface and the thickness at that point On the other hand, in a steady state, where the accumulation of snow on the upper surface is just balanced by the outward flow, u is also determined by the rate of accumulation of snow, integrated between the place under consideration and the 'centre' of the ice sheet This makes it possible, in principle, to calculate the steady-state profile of the upper surface, and with certain simplifying assumptions, such as uniform roughness of the bed, some analytical solutions can be derived[4]

Our present concern, however, is with departures from the steady state, and here the appropriate analysis has already been performed by Weertman[7] He uses equation (2) and considers an ice sheet moving down a uniform plane bed of slope β in the direction Ox , the assumption of uniform slope is not in fact necessary, and we may put β a function of x without altering the result (The effect of non-uniform roughness is treated in ref 4) In the steady state, the thickness is $h_0(x)$, the velocity is $u_0(x)$, and the thickness of ice added at the upper surface per unit time is $a(x)$ We put $dh_0/dx = -\varphi_0$ (φ_0 is positive) and $\alpha_0 = \varphi_0 + \beta$, so that α_0 is the steady-state slope of the upper surface Let there now be a departure $h_1\ (x, t)$ from the steady-state thickness, where $h_1 \ll h_0$, $\partial h_1/\partial x \ll \varphi_0$, $\partial h_1/\partial x \ll \alpha_0$, $\partial^2 h_1/\partial x^2 \ll d\alpha_0/dx$ Weertman then shows, solely from equation (2) and an equation of continuity, that the subsequent history of this perturbation is given by

$$\frac{\partial h_1}{\partial t} = -Bh_1 - C\frac{\partial h_1}{\partial x} + D\frac{\partial^2 h_1}{\partial x^2} \tag{3}$$

B, C and D being fixed by the steady-state parameters as follows

$$\left.\begin{aligned} B &= (m+1)(\varphi_0 u_0 + a)/h_0 \\ C &= \{(m+1)(\alpha_0 + \varphi_0)u_0 - (m-1)a\}/\alpha_0 \\ D &= m u_0 h_0/\alpha_0 \end{aligned}\right\}$$

The three terms on the right in equation (3) have simple meanings[7] The term $-Bh_1$ represents an exponential decay with a time constant B^{-1} Putting $m = 2\ 5$, $h_0 = 3{,}000$ m , $u_0 = 20$ m /yr , $\varphi_0 = 3 \times 10^{-3}$, $a = 0\ 1$ m /yr gives $B^{-1} = 5{,}000$ yr This term is concerned with departures from the equilibrium thickness, rather than from the equilibrium slope It shows that such departures, extending, as we shall see, over long distances comparable with the size of the whole ice sheet, can persist for several thousand years—long, that is, compared with the period for which the rate of accumulation can be considered steady The term $-C\partial h_1/\partial x$ represents a travelling wave of constant h_1 moving with a velocity C This wave is akin to the kinematic waves of Lighthill and Whitham[8] Putting $\alpha_0 = \varphi_0$ and the other values as before gives $C = 90$ m /yr (We may note in passing that, for small u_0, C can be negative that is, the wave can travel upstream This happens up to distances of about 200 km from the centre) The term $D\partial^2 h_1/\partial x^2$, which is the one of primary interest in the present application, represents an outward spreading and broadening of an initial disturbance in accordance with the diffusion equation The characteristic time for the 'diffusion' process will depend on the length of the waves If there are surface waves of wave-length λ, the characteristic time will be[4] $\left(B + \frac{4\pi^2 D}{\lambda^2}\right)^{-1}$ Putting in numerical values as before and taking $\lambda = 12$ km (the mean observed wave-length), we find the time to be 0 07 yr (B is negligible here) Thus surface waves as short as 12 km will disappear in a matter of months In order to survive for one year, a wave would need to have $\lambda > 40$ km , and for 10 years, $\lambda > 140$ km A wave with $\lambda/2$ equal to the width of the ice sheet 4,000 km) would last for 5,000 years At the other extreme we must recognize that the approximations of the theory break down when the wave-length becomes smaller than the thickness of the ice sheet, ay, 3 km , and waves with $\lambda \ll 3$ km —sastrugi, or example—will not be eliminated by the above mechanism Thus we conclude that departures from he equilibrium form of the ice sheet cannot survive or longer than one year if their wave-lengths are between about 3 (or less) and 40 km

The physical reason for this result may be explained s follows The upstream side of a crest will have a maller slope than normal, and the downstream side will have a greater slope This causes a greater shear tress on the bed, and therefore a greater velocity, on he downstream side The crest is therefore stretched nd flattened If, however, the crest is narrow compared with the depth of the ice sheet, as in sastrugi, he changes of slope do not affect the shear stress on he bed, and so the crest survives At the other xtreme, if the crest is very extensive, the additional urvature of the surface is so slight that a long time is eeded to eliminate it Between these two extremes here is a range of wave-lengths where the crests sappear in times less than one year

It follows from this analysis that, if comparatively ng-lived undulations are observed in the range of ave-lengths where waves are quickly eliminated, ey cannot be departures from the equilibrium ofile but are the result of the topography of the d This conclusion, from purely mechanical reasoning, will apply to the surface waves with $\lambda \sim 12$ km en in Antarctica, provided the waves cannot build by preferential accumulation in very short times cording to the above figures they could only be e to preferential accumulation if they were built within a few months—and this seems exceedingly likely in view of the measurements of annual cumulation interpreted from cores drilled on the ves by the Trans-Antarctic Expedition during e crossing[1,2] Incidentally, if our conclusion that e waves are the result of bed topography is rrect, one might expect to find the accumulation ther greater in the sheltered hollows than on the posed crests, and this does appear to be the case[1]

We must now ask how the topography of the bed ll influence the surface If m were infinite, equation (1) shows that the velocity of sliding would be zero up to a critical shear stress A, and, when $\tau = A$, u could take any value Putting m infinite in fact leads to the older theory[6] in which τ was regarded as constant everywhere on the bed of an ice sheet In this approximation, therefore, h is proportional to $1/\alpha$ Using this approximation, Bourgoin[3] has succeeded in making a detailed correlation between the very slight relief of the surface of the Greenland ice sheet and the relief of the bed measured by seismic sounding He found that an unevenness of the surface of as little as 10 m between two points 30 km apart denoted the presence of a hill in the bed rock about 350 m high This theory can now be improved by using the more general relation (1), in which m is finite and which allows for changes in τ It is then found[4] that a hill on the bed of height p, where $p \ll h$, produces (a) a change in height of the surface which is an order of magnitude less than p, (b) a change $\Delta\alpha$ in surface slope where

$$\frac{\Delta\alpha}{\alpha} = \frac{m+1}{m}\,\frac{p}{h} \simeq 1\ 4\,\frac{p}{h} \qquad (4)$$

and (c) a change $\Delta\tau$ of shear stress on the bed, where

$$\frac{\Delta\tau}{\tau} = \frac{1}{m}\,\frac{p}{h} \simeq 0\ 4\,\frac{p}{h} \qquad (5)$$

Thus a mountain 300 m high covered by ice 3,000 m thick shows itself as a change in height of the surface small compared with 300 m (as verified by Bourgoin's work), a change in surface slope of 14 per cent, and a change of shear stress on the bed of 4 per cent The smallness of this last figure is the reason for the success of the older theory in which τ was regarded as constant

In order to deduce the height of a buried mountain from the change of slope of the surface that it produces, we write (4) as

$$p = \frac{m}{m+1}\,\frac{h\Delta\alpha}{\alpha} \simeq 0\ 7\,\frac{h\Delta\alpha}{\alpha} \qquad (6)$$

The value of p deduced by putting m infinite is $h\,\Delta\alpha/\alpha$ Thus with the new theory, which allows τ to vary, we deduce values of p which are 70 per cent of those deduced on the older theory Generally speaking the accuracy of the seismic methods used in Greenland (and Antarctica) is not yet sufficient to check this change in the theoretical prediction

The fluctuations of surface slope observed in Antarctica are comparable with the average slope itself, and it follows from (4) that the heights of the submerged mountains are a large fraction of the total thickness of the ice sheet We are thus left with the conclusion that the surface waves in Antarctica, small as they are, reflect a very considerable relief of the rock bed—a relief which is already becoming apparent from the seismic and gravity work Greenland is very different , there the bed is comparatively uniform in the regions so far studied, and this shows itself in the extreme uniformity of the surface

NUCLEOTIDE-PEPTIDE COMPOUNDS OF *SACCHAROMYCES CEREVISIAE*

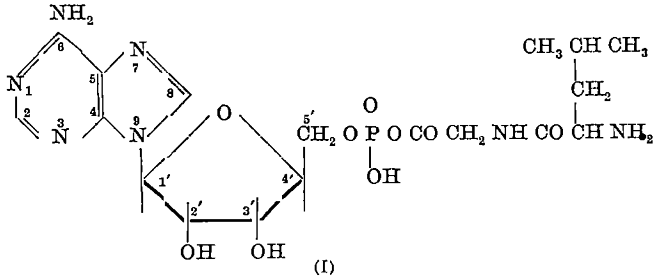
By G. HARRIS and J W DAVIES
Brewing Industry Research Foundation, Nutfield, Surrey

Synthetic 'Active' Nucleotide-Peptide Compounds

THE recent demonstration[1] of the presence in strains of *Saccharomyces cerevisiae* of nucleotide-peptide compounds containing an active carboxyl group in the peptide moiety and the isolation of individual compounds of this nature[2], which may function as protein precursors, made it clearly desirable to prepare model 'active' compounds

Methods already available[3-6] for the synthesis of the related amino-acid adenylates have therefore been applied to the elaboration of certain nucleotide-peptide compounds For example, application of the method of Berg[3], as modified by Kingdon *et al* [4] to the condensation by means of di*cyclo*hexyl carbodiimide in aqueous pyridine of adenylic acid with leucylglycine, has yielded a mixed nucleotide-peptide anhydride, although only in small yield The crude product was obtained from the reaction mixture by precipitating it by means of acetone, extracting the dried precipitate with weak acetate buffer at *p*H 4 0 and removing contaminating adenylic acid and polymers by adsorption of these impurities on 'Dowex-1' (formate) It was further purified by chromatography on Whatman 3 *MM* paper in the solvent system, *n*-propanol-ethyl acetate-water (7 1 2, v/v), elution with cold water and evaporation of the resulting solution in the cold

The product had an R_F value of 0 20 in the above chromatographic solvent and was therefore well differentiated from unchanged leucylglycine having an R_F value of 0 32 It gave a characteristic red coloration with ninhydrin reagent on paper and a strong red-brown coloration due to the formation of a ferric hydroxamate on treatment with hydroxylamine followed by ferric chloride under the conditions recommended by Koningsberger *et al* [1] These colour reactions and the behaviour of the compound on 'Dowex-1' (formate) resemble closely those given by the corresponding products from yeast With the latter, the synthetic compound shares also the further characteristic properties of migrating towards the cathode on electrophoresis on paper in acetate buffer at *p*H 4 0 and of having an ultra-violet absorption spectrum of the type given by the corresponding nucleoside From a consideration of its properties, the mode of synthesis and the fact that the compound yielded on hydrolysis equimolar proportions of adenine, ribose, phosphoric acid, leucine and glycine it may be deduced that the nucleotide-peptide has the structure (I) This resembles closely certain of the yeast constituents which, however, contain uracil in place of adenine, and it is of interest to record that replacement in the above synthesis of adenylic acid by uridylic acid results in the formation of a product of very similar properties with the exception that it is less readily desorbed from 'Dowex-1' (formate) Again, the substitution of the tripeptide DL-leucyglycylglycine for the above dipeptide yields analogous products, and present efforts are therefore being made to extend the synthesis to certain of the naturally occurring nucleotide-peptide compounds

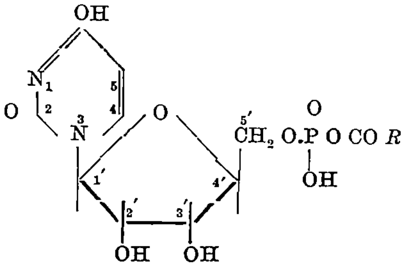


(I)

A Second Nucleotide-Peptide Compound from Brewers' Yeast: Isolation and Structural Observations

THE initial discovery[2] of a nucleotide-peptide compound in cold ethanol extracts of a brewer's yeas and the possibility that such compounds might play a part in protein synthesis prompted a search fo other substances of this nature It has now been observed that extraction of *Saccharomyces cerevisia* (No 240 of the British National Collection of Yeas Cultures) by means of hot aqueous ethanol, following inactivation of the cells with cold ethanol and ether yields a mixture containing several nucleotide-peptide compounds Treatment of the extract with 'Dowex-1' (chloride) resulted in adsorption of certain of these compounds among others on the resin, whil desorption of some of the adsorbed material wa achieved by treatment of the resin with acetat buffer solution at *p*H 5 0 The concentrate thu obtained was freed from various nucleotides, peptide and amino-acids by successive adsorption of thes compounds on 'Dowex-1' (formate) and 'Amberlit *CG* 50' (acid form) and was then subjected to electrophoresis in acetate buffer at *p*H 4 0 on Whatman No 3 paper Elution by means of cold water of tha material on the final electropherogram which had th properties of (*a*) migrating towards the cathode (*b*) reacting with hydroxylamine to form a hydroxami acid[1,2], and (*c*) yielding a coloration with ninhydrin gave a preparation, which on freeze-drying an freeing from salt by solution in wet ethanol, followe by precipitation with ether, yielded a homogeneous nucleotide-peptide

The product migrated as a single narrow band on electrophoresis as above an formed one well-defined chromatographi zone in the solvent systems compose (*a*) of butanol, acetic acid and water (4 1 v/v), and (*b*) of ethyl acetate, propan and water (1 7 2, v/v) As indicate above, it formed a hydroxamic acid o reacting with hydroxylamine under th conditions described by Koningsberger il[1] and it gave a red coloration on heating with ninhydrin In acid solution, its absorption spectrum displayed maxima at 235 and 265 mμ, the peaks corresponding presumably to the absorption due to the peptide and nucleotide moieties, respectively The molecule was broken down into its constituent parts by treatment with cold alkalis, for example odium hydroxide, aqueous ammonia or hydroxylamine, the nucleotide portion displaying the chromatographic[7], electrophoretic and light absorption properties characteristic of uridine-5′-phosphate The peptide-hydroxamic acid formed by treatment of the original nucleotide peptide with hydroxylamine behaved chromatographically as a single ubstance which on hydrolysis with acid yielded only arginine and α-alanine as judged by chromatoraphy and colour reactions[8] The treatment with lkalis naturally resulted in the loss of reactivity owards hydroxylamine



(II)

here R represents a tetrapeptide residue consisting f two arginine and two α-alanine units

The presence of a uridylic acid residue in the ucleotide–peptide compound was confirmed by ydrolysing the latter material (*a*) with formic acid o produce uracil, itself estimated by ion-exchange romatography[9], (*b*) phosphate[10] (1 mole), and) ribose (1 mole)[11,12] The composition of the peptide was ascertained by hydrolysis with hydrochloric acid followed by chromatography on paper The arginine and α-alanine were eluted by means of dilute acid and estimated by the colorimetric method of Yemm and Cocking[13], whereupon it was found that the molecule contained two residues each of the above amino-acids The evidence indicates that the nucleotide–peptide now described is a mixed anhydride (II) of uridine-5′-phosphate with a tetrapeptide containing two units of α-alanine and two units of arginine The site of the 'active' anhydride grouping at the 5′-position of the uridine-5′-phosphate is indicated (*a*) by the loss of reactivity towards hydroxylamine coincident with fission of the molecule by means of alkalis, (*b*) the formation of a peptide-hydroxamic acid, and (*c*) by the fact that the compound itself is immediately attacked by periodate, thus demonstrating the lack of substituents on the 2′ and 3′ positions The close structural relationship between the nucleotide–peptide here described and the mixed 5′-phosphoanhydrides of adenosine-5′-phosphate with various single amino-acids, taken together with the fact that the latter anhydrides are held to be implicated in protein synthesis, suggests that the peptide derivatives also might play a part in cell growth

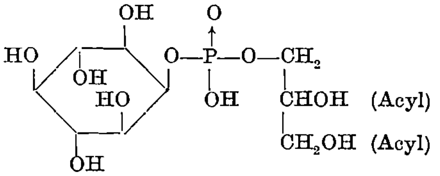
SYNTHESIS AND PROPERTIES OF 1-GLYCERYL-2-*MYO*-INOSITYL PHOSPHATE

THE simplest member of the glycerinositol phosphatides[1] is considered to be a diacyl derivative of 1-glyceryl-2-*myo*-inosityl phosphate)[2–4], since on hydrolysis it yields glycerol, *myo*-ositol, glyceryl phosphate, *myo*-inosityl phosphate nd fatty acids, the ratio fatty acids, glycerol, ositol, phosphorus being 2 1 1 1



(I)

Although there is strong evidence for formula (I), ubt still exists concerning the position of the hosphate group because of its tendency to migrate adjacent hydroxyl sites under the conditions hydrolysis[5,6] We have therefore synthesized 1-glyceryl-2-*myo*-inosityl phosphate for comparison with the natural product This was kindly undertaken by Dr J N Hawthorne, who found our synthetic product identical with his own specimen, isolated from ox liver and with a specimen synthesized by a different route (see second communication)

T MALKIN

Synthesis of 1-Glyceryl-2-*myo*-inosityl Phosphate

3 4 5 6-TETRACETYL-*myo*-INOSITOL[7] in pyridine, when treated with 1 25 moles of acetyl chloride in benzene, yielded 1 3 4 5 6-pentacetyl-*myo*-inositol in 78 per cent yield, shown by mixed m p 172–74° C , and mixed m p of *p*-nitrobenzoyl esters 232–35° C , to be identical with the pentacetate obtained by the stereospecific reduction of pentacetyl-*scyllo*-inosose[8–10] This pentacetate, when treated with phenylphosphorodichloride, 1 1 moles, in lutidine at 40° C for 48 hr , followed by addition of 1 2-*iso*propylidene-

glycerol, 5 moles, at 50° C , and stirring for 36 hr , gave 1 2-*iso*propylidene-glyceryl-pentacetyl-2-*myo*-inosityl-phenylphosphate, as colourless crystals from ethanol, m p 140–42° C , in 52 per cent yield (found C, 51 0 , H, 5 7 , P, 4 7 $C_{28}H_{37}O_{16}P$ requires C, 50 9 , H, 5 6 , P, 4 7 per cent Hydrogenolysis in ethanol or ethyl acetate, in the presence of Adams's catalyst, removed the phenyl group, and the resultant acidity was sufficient to cause the loss of the *iso*propylidene group, on dissolution in water and standing overnight Evaporation of the solvent at < 40° C gave the glyceryl-pentacetyl-inosityl-phosphate as a deliquescent glass, which was characterized as the *cyclo*hexylamine salt, m p 204° C (found C, 46 2 , H, 6 7 , N, 2 2 , P, 4 7 per cent , $C_{25}H_{42}O_{18}P\,N$ requires C, 46 6 , H, 6 5 , N, 2 2 , P, 4 8 per cent Sodium methylate in methanol converted the pentacetyl compound into sodium glyceryl-*myo*-inosityl-phosphate, which was separated in a centrifuge and converted into the free acid by passing an aqueous solution down a column of '*IR* 120' resin Evaporation to dryness at < 40° C gave a deliquescent glass, which was quite unsuitable for characterization or for handling Sodium, potassium and barium salts were made by passing an aqueous solution of the phosphate down a column of '*IR* 120' resin in the appropriate basic form Both the former are very deliquescent, but the latter is less so and can be handled reasonably well The removal of protecting groups is carried out with an overall yield of 70–75 per cent

Since most of the natural glyceryl phosphatides occur in the L-form, we have carried out the same synthesis, using D-*iso*propylidene glycerol[11], which yields the L-glyceryl phosphate , but although various optically active intermediates were obtained, the final glyceryl-inosityl-phosphate was inactive Racemization is, of course, to be expected, once the protecting *iso*propylidene group is removed, because of the phosphate equilibrium between the 1 2-positions of the glycerol, and this appears to be particularly rapid, when all the protecting groups are removed It is, however perhaps too early to discuss this aspect of the work in detail, as so little is yet known about the activity of the natural compounds

L-*iso*propylidene-glyceryl-1 3 4 5 6-pentacetyl-*myo*-inosityl-phenyl-phosphate was made as described for the DL-compound The m p and mixed m p with the DL-compound are surprisingly the same (140–42° C) , $[\alpha]_D^{21}$° + 2 34° C in chloroform, $[\alpha]_D^{21}$° + 2 4 in ethyl acetate

Hydrogenolysis of the above and neutralization with $N/10$ sodium hydroxide (phenolphthalein) gave sodium L-*iso*propylidene-glyceryl-1 3 4 5 6-pentacetyl-*myo*-inosityl-phosphate , $[\alpha]_D^{21}$° + 3 25° C , in chloroform (found C, 43 3 , H, 5 2 , P, 5 0 $C_{22}H_{32}O_{16}P\,Na$ requires C, 43 5 , H, 5 2 , P, 5 0 per cent) This, on deacetylation, gave sodium L-*iso*propylidene-glyceryl-*myo*-inosityl-phosphate as a deliquescent white powder , $[\alpha]_D^{21}$° − 1 04° C in water

For comparison with the natural products, we sent the barium salt of glyceryl-*myo*-inosityl phosphate, prepared from D-*iso*propylidene glycerol, to Dr J N Hawthorne Our own hydrolysis and paper chromatographic comparisons showed it to be identical with that obtained from inactive *iso*propylidene glycerol

1-Glyceryl-2-*myo*-inositol Phosphate: Alternative Synthesis and Behaviour on Hydrolysis

BY a mild alkaline hydrolysis of liver phosphatidy inositol (Formula I, previous communication) th two fatty acids have been selectively removed, an glyceryl-*myo*-inosityl phosphate prepared Afte purification on an ion-exchange column, it has bee broken down to a mixture of glycerophosphate an inositol monophosphate by hydrolysis with 0 5 *N* sodium hydroxide at 100° C for 40 min[12] Fc comparison with glyceryl-*myo*-inosityl phosphat prepared in this way, a synthetic sample was require 1-Glyceryl-2-*myo*-inosityl phosphate was chosen fc this work

The method of phosphorylation used in the preser synthesis is that which has been developed by Gilhai and Khorana[13] a phosphate monoester and a alcohol, under the influence of di*cyclo*hexylcarbod imide in anhydrous pyridine, condense together give a phosphate diester (This work began befo the method of Gilham and Khorana appeared W are grateful to Dr Khorana for sending details advance of publication) This method has n previously been applied to the syntheses of phosph lipids or their intermediates

The alcohol used in the present work was DL-*is* propylidene glycerol[14] and the phosphate monoest was 1 3 4 5 6-penta-acetyl-*myo*-inositol-2-pho phate This latter compound was prepared by modification of Iselin's five-stage synthesis[8] *my* inositol was oxidized by *Acetobacter suboxydans* scyllo-inosose This was acetylated to its penta acetate with acetic anhydride containing 0 3 per cer perchloric acid The catalytic reduction of th compound is difficult[10], presumably because th carbonyl group is sterically hindered and it wa eventually found necessary to carry out the hydr genation in glacial acetic acid The reaction is n completely stereospecific in this solvent and a mixtu of *myo*-inositol and scyllitol penta-acetates is forme The mixture was phosphorylated with diphen phosphorochloridate in pyridine at 80° C for 20 h The product, recrystallized from dry ethanol, ha m p 183–88° C The yield was 66 per cent Th phenyl groups were removed by hydrogenolysis dry ethanol with Adams's catalyst, and the contan inating scyllitol isomer was then removed by fraction crystallization from the concentrated ethanol solutic at room temperature , the penta-acetyl scyllit phosphate had m p 249–51° C , yield 5 per cen the penta-acetyl inositol phosphate had m p 23 32° C after recrystallizing from dry ethanol, yie 64 per cent

DL-*iso*propylidene glycerol (0 5 ml) and pent acetyl inositol-2-phosphoric acid (0 2 m mole) we allowed to react together in anhydrous pyridi (5 ml) with di*cyclo*hexylcarbodiimide (1 5 m mole for 2 days at room temperature Water was add and the precipitated di*cyclo*hexylurea removed centrifugation The *iso*propylidene group was moved by stirring with a large excess of 'Zeo-Karb 22 (H^+-form) overnight The solution was concentrat to a small volume *in vacuo* at a bath temperatu of less than 40° C and the acetyls removed as the hydroxamates hydroxylamine was prepared reaction of its hydrochloride with the calculat amount of sodium metal in dry methanol and add in excess to the phosphate solution It was allow to react for 20 min

The reaction mixture contained 25–30 per cent glyceryl-*myo*-inosityl phosphate, free inositol monophosphate, and a third component which is probably *bis* inositol pyrophosphate These compounds were separated by chromatography on 'Dowex-1' using borate–formate mixtures for elution[12] The synthetic glyceryl-*myo*-inosityl phosphate was eluted at the same formate concentration as the natural material Determination of glycerol by the chromotropic acid method[4b] showed a glycerol to phosphorus molar atio of 1 0(03)/1

The synthetic product was subjected to the same alkaline hydrolysis that has been used for the glyceryl-*myo*-inosityl phosphate isolated from the inositide The hydrolysate, complexed with borate in he usual manner, was analysed into its components n a 'Nalcite *SAR*' column[4b] No phosphate was ow eluted with the glyceryl-*myo*-inosityl phosphate luting agent, but two peaks appeared in the positions where inositol monophosphate and glycerophosphate re known to occur Only the second, corresponding o glycerophosphate, contained glycerol 31 per cent f the phosphorus was present in the inositol phoshate peak

For comparison, the barium salt of glyceryl-*myo*-nosityl phosphoric acid prepared in the Bristol aboratories was hydrolysed by the same method Analysis by the chromotropic acid method showed hat it contained the theoretical amount of glycerol The inositol monophosphate and glycerophosphate roduced by hydrolysis were separated on a column s above In two analyses 31 and 35 per cent of the hosphate in the hydrolysate was in the form of nositol monophosphate

This hydrolytic pattern agrees well with that obtained with glyceryl-*myo*-inosityl phosphate prepared from the liver phosphatidyl inositol[12] In addition, Hanahan and Olley[15] found that alkaline hydrolysis of the lipid itself gave 35 per cent phosphorus in the form of inositol phosphate It is likely, therefore, that the natural product has a similar configuration, involving inositol-2- or 1-phosphate A decision between these two should be possible since only the 1-compound is optically active[16]

FUNCTIONAL ORGANIZATION OF THE RESPIRATORY CHAIN IN LIVER MITOCHONDRIA

By DR TOKUJI KIMURA and DR THOMAS P SINGER*
Edsel B Ford Institute for Medical Research, Henry Ford Hospital, Detroit

THE question of whether the mitochondrion is compartmentalized into separate respiratory ains serving the individual cytochrome-linked hydrogenases and acting independently of each her, or whether all or most of these dehydronases are structurally and functionally linked to common electron transport system, has been an en and much debated one In the past, two major proaches have been used to explore this question ne entails the isolation of mitochondrial fragments pable of oxidizing only one substrate at significant tes (such as a reduced diphosphopyridine nucleotide idase preparation[1]) and the other the measurement the extent of reduction of the various cytochrome mponents in anaerobiosis in intact mitochondria[2] sewhere[3], we have discussed the limitations of these thods and the consequent uncertainties of the nclusions derived from their application A series alternative methods have been employed by ngler and Singer[3,4] to a study of the respiratory ain in brain mitochondria and some of the same thods have been applied by Wu and Tsou[5] to ilin–Hartree preparations of pig heart in their study the interrelation of succinic and reduced diphosphoridine nucleotide oxidases

The following possibilities have been considered in the present study (1) There may be a separate and distinct cytochrome chain serving each cytochrome-reducing dehydrogenase in mitochondria, with no interconnexion between the chains (2) Two or more dehydrogenases may be attached to any given chain, but there is no functional interconnexion between the chains (3) Two or more dehydrogenases may be linked to a given cytochrome chain, and there is intercommunication (that is, electron transport) among all the chains in a given mitochondrion The third alternative recognizes the least degree of specialization for the electron transport system Both alternatives (2) and (3) pose the further question as to the point in the chain at which a bifurcation to the various dehydrogenases might occur In the present investigation these alternatives were examined in sucrose mitochondria of rat liver, using the succinic and choline oxidase systems as indicators, since both specific dehydrogenases have been isolated and sufficiently characterized to permit the conclusion that they are flavoproteins The techniques employed in order to decide among the aforementioned possibilities included (*a*) a study of the rate of the cross-reaction in anaerobiosis between the two dehydrogenases and of the effect of inhibitors thereon ;

* Established investigator of the American Heart Association

Table 1 COMPETITION OF SUCCINIC AND CHOLINE DEHYDROGENASES FOR THE RESPIRATORY CHAIN

Experiment	Electron acceptor	Substrate	Oxygen uptake (μ atoms)	Fumarate formed (μ moles)
1	Respiratory chain, cyt a_3 limiting (3 3 m*M* azide)	Succinate Choline Succinate + choline	40 0 20 0 35 6	36 0 28 0
2	Phenazine methosulphate	Succinate* Choline Succinate* + choline	51 2 55 4 112	
3	Respiratory chain, cyt $b \rightarrow c_1$ limiting (9 3 × 10^{-7} *M* quinoline oxide)	Succinate Choline Succinate – choline	22 2 12 5 36 1	22 8 24 6

* Succinic dehydrogenase activity depressed by titration with malonate to the level of choline dehydrogenase

Conditions Manometric assays at 30°, *p*H 7 6, in the presence of 0 02 *M* succinate and/or 0 017 *M* choline and sucrose mitochondria of rat liver The reaction period and the amount of mitochondria were varied in the different experiments, but the results are expressed for a 15-min period and 1 ml mitochondrial suspension The latter contained 25 2 mgm protein in experiments 1 and 2, and 25 9 mgm in experiment 3 In experiments 1 and 3, 0 5 mgm cyt *c* was added Fumarate was determined, after deproteinization, with crystalline fumarase and the malic enzyme of *L arabinosus* (ref 9)

(*b*) comparison of the quantitative effect of the titration of mitochondria with respiratory chain inhibitors on the two enzyme systems , (*c*) a study of the effect of depletion and re-addition of a specific component of the respiratory chain on the two activities , (*d*) competition experiments between the two enzyme systems for specific components of the respiratory chain

The investigations of Slater[6] and of Wu and Tsou[5] of the reduced diphosphopyridine nucleotide and succinic oxidases of heart and of Ringler and Singer[3 4] of the succinic and α-glycerophosphoric oxidases of brain have ruled out the possibility that separate and specific cytochrome chains serve these dehydrogenases in the tissues mentioned, but did not permit distinguishing between alternatives (2) and (3) In contrast, the results of a comparison of the behaviour of choline and succinic oxidases in rat liver did not seem to be readily reconcilable with the operation of a common respiratory chain and suggested that at least a part of their cytochrome chains may operate independently of each other Thus, anaerobically, no oxidation of choline by fumarate could be detected, the oxidation of choline and succinate via the complete chain was additive, not competitive , addition of cytochrome *c* to partially depleted mitochondria stimulated succinate oxidation three- to four-fold but did not affect choline oxidation, and titration with azide, cyanide, antimycin *a*, and 2-*n*-heptyl-4-hydroxyquinoline N-oxide (quinoline oxide) inhibited succinate oxidation at much lower concentrations than choline oxidation (Fig 1) Further, amytal completely inhibited choline respiration without inhibiting succinate oxidation

Since during the steady state both choline and succinate reduce all the known cytochromes of liver mitochondria (b, $c + c_1$, a, a_3), although to different extents[8], and since the differential effects of amytal were readily explained, without postulating separate pathways, by the finding that this inhibitor acts between choline dehydrogenase flavoprotein and cytochrome *b*[8], it was desirable to establish whether the differential effects on choline and succinic oxidases might not be the results of the greater activity of succinic than of choline dehydrogenase and of the consequently greater demand it puts on the respiratory chain In order to test this possibility, succinic dehydrogenase activity was depressed by malonate to a point where it equalled choline dehydrogenase activity Under these conditions, external cytochrome *c* no longer stimulated either succinic or choline oxidase, since the residual cytochrome *c* in washed sucrose mitochondria was sufficient to support this lowered rate of respiration Similarly, when succinic and choline dehydrogenase activities were equalized by malonate titration, the titration curves of choline and succinic oxidases (and of the corresponding cytochrome *c* reductases) with all the respiratory chain inhibitors mentioned coincided

Since the activity of choline oxidase in rat liver mitochondria is only 20–25 per cent as high as that of succinic oxidase, it seemed possible that the turnover-rate of the slowest member of the cytochrome chain in liver mitochondria (supplemented with cytochrome c) may exceed the combined activity of the two oxidases and that, therefore, in order to demonstrate a competition between the two oxidases it is necessary to depress the turnover of one of the components of the respiratory chain Indeed, when the turnover of cytochrome a_3 was depressed by titration with azide, the mutual competition of choline and succinic oxidases could be readily demonstrated (Table 1, exp 1) Significantly, as in the mutual competition of succinic and α-glycerophosphoric dehydrogenases in brain mitochondria, when the two substrates are simultaneously oxidized, the rate is *less* than that of the faster of the two oxidations The reasons for this have been discussed elsewhere[4] That the depression of succinate oxidation is the direct result of the operation of choline dehydrogenase is shown by the fact that the addition of 3 m*M* amytal, under these conditions, completely inhibits choline oxidation and re-establishes the rate of succinate oxidation and fumarate formation to the level found with succinate alone present When the respiratory chain is by-passed by intercepting electrons with phenazine methosulphate (exp 2) the competition disappears and a strict additiveness is obtained It may be concluded that the electrons originating from these two dehydrogenases flow through a common transport system, at least at the level of cytochrome oxidase

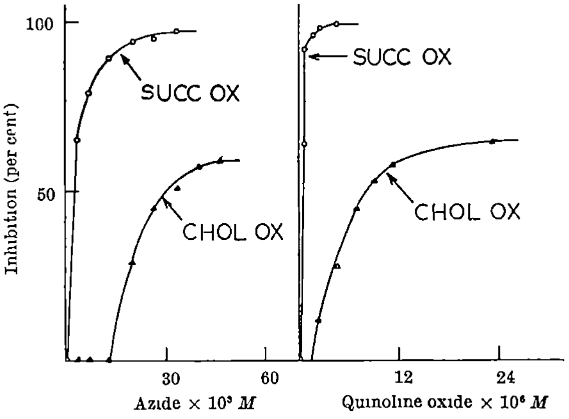

Fig 1 Titration of succinic oxidase and choline oxidase activities of sucrose mitochondria of rat liver with respiratory chain inhibitors Manometric assay of uptake of oxygen at 30° as in Table 1 The inhibitions were calculated from the linear rate of respiration in the interval 5–20 min after addition of the substrate The initial rate of respiration (0–5 min), before the inhibitor-resistant oxidation of choline is manifest (cf below), gives similar differences in the titration of the two oxidases, but the inhibition of both enzymes reaches completion

When antimycin or quinoline oxide was used to limit the rate of the cytochrome $b \rightarrow c_1$ step, instead of competition, additive rates were obtained (exp 3) This is interpreted to mean that the cytochrome b moieties serving succinic and choline dehydrogenases are not the same nor in direct intercommunication. Further support for this conclusion came from a detailed study of the azide-, CN^--, antimycin- and quinoline oxide-resistant oxidation of choline (Fig 1) Using an oxygen electrode, it was demonstrated that immediately following the addition of choline to mitochondria, treated with any of these inhibitors in excess, the oxidation is completely inhibited, but after 3–5 min at 30° C or after 10–20 min at room temperature, a respiration resistant to all these inhibitors begins The cytochrome *b* linked to choline dehydrogenase (but not that linked to succinic dehydrogenase) appears to be the site of the 'leak' and the resistance to inhibitors is thought to represent a conversion of this cytochrome *b* to an auto-oxidizable form for the following reasons (1) Choline dehydrogenase is not auto-oxidizable (2) Amytal inhibition of choline oxidation is complete but antimycin or quinoline oxide inhibition is not Thus, the 'leak' is between flavoprotein and cytochrome c_1 (3) Choline-cytochrome *c* reductase is completely blocked by all three of these inhibitors (4) The auto-oxidizable component through which succinate and choline oxidations occur with excess azide or CN^- present is he same, since under these conditions the rate of espiration per mgm mitochondria is equal whether uccinate, choline, or both are present Thus, the two ehydrogenases compete for the leak (5) That the *b* omponent linked to choline dehydrogenase (and not hat serving succinic dehydrogenase) is the site of the eak is indicated by the fact that while choline xidation is partially resistant to antimycin and uinolineoxide (agents which inhibit the $b \rightarrow c_1$ tep), succinic oxidase is completely inhibited by hese compounds

The auto-oxidation or reduced cytochrome *b* in ertain types of heart muscle preparations in the resence of cyanide was first observed by Keilin[10] ecently, Chance[11] questioned the evidence for the rect reaction of cytochrome *b* with oxygen at a gnificant rate In view of the slow rate of he development of the cyanide- and azide-resistant spiration in liver mitochondria, the auto-oxi- ation of cytochrome *b* possibly may escape tection in spectrophotometric experiments of very short duration, as employed by the Philadelphia group[11,12]

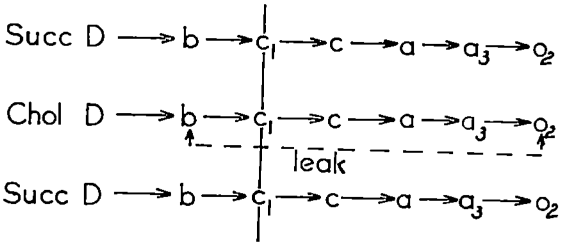

Fig 2 Schematic representation of the interrelations of succinic and choline oxidases in rat liver mitochondria

The findings suggest that the respiratory chains of liver mitochondria, at least so far as the succinic and choline oxidase systems are concerned, are not compartmentalized, but are interlinked at and above the oxidation-level of cytochrome c_1, although the *b* components do not appear to be on a common path (Fig 2) Intercommunication between the chains (alternative (3) above) is indicated by the fact that the quantitative effect of titration with an inhibitor, such as azide or cyanide, depends on the relative turnover rates of the dehydrogenase and the cytochrome component being titrated, respectively, and may be altered by depressing the activity of the dehydrogenase Neither mechanism (1) nor (2) is compatible with this behaviour, but it is to be expected from the third one

IS THE MULTIMAMMATE RAT A NATURAL RESERVOIR OF *BORRELIA DUTTONI*?

By Dr. F. ZUMPT
Department of Entomology, South African Institute for Medical Research, Johannesburg

OR about two years now, the Entomological Department of the South African Institute for edical Research, Johannesburg, has been carrying t transmission experiments and epidemiological vestigations on relapsing fever (*Borrelia duttoni*) in chuanaland, in collaboration with the Medical partment of that Protectorate

With the help of Dr E L Szlamp, medical officer Maun, a strain of *Borrelia duttoni* was isolated m tampans (*Ornithodoros moubata*) collected in a t in Maun, inhabited by a native suffering from an acute attack of relapsing fever Eleven specimens of *O moubata* were collected on December 5, 1958, and were injected into six white mice on December 17 All the mice became positive between December 23 and 29, 1958

This 'Maun' strain was then used for a great number of transmission experiments, on which a report will be given in a later paper Up to now, quite a few interesting results have been obtained, but one is of special interest and is reported in this preliminary note In our search for the natural reservoirs of African relapsing fever, which I expect to find among wild rodents, we also injected several specimens of the indigenous multimammate rat (*Rattus natalensis* = *Mastomys coucha*) with the 'Maun' strain and found that this wild rat is very highly susceptible to *Borrelia duttoni* although, judging from the general appearance and behaviour of the animals, there are no obvious clinical symptoms The same is true for the white mouse, but in the multimammate rat the parasitæmia of the blood is much higher, and persists, almost without interruption, for a longer period A photomicrograph of a blood smear of a white mouse at the peak of the blood-parasitæmia (ninth day after subcutaneous injection) is shown in Fig 1, and one of a blood-smear from a multimammate rat at a corresponding peak (eleventh day after injection) is given in Fig 2

The course of the infection in the above-mentioned white mouse was as follows It was infected on June 2, 1959, with an emulsion of eggs laid by an infected *O moubata* The first few spirochætes were detected in the blood-smear on June 10 The next day the smear was positive (Fig 1), and it did not reach this degree of parasitæmia again On June 13, only a few spirochætes were present in the field On the two following days the blood smears were negative On June 17 the result was recorded as + + A few spirochætes were again detected in the smear on June 20, 24 and 27 On the intervening days, and after June 27, all smears were found to be negative

The specimen of multimammate rat was injected on June 2 with a brain emulsion from a white mouse On June 9, the first spirochætes appeared in the blood and were recorded as ++ The next day no spirochætes could be detected in the smear They re-appeared on June 11 and increased steadily until June 15, when they reached the peak shown in Fig 2 The rat then remained highly positive until June 27 On the following two days the blood was negative , then another peak was reached on July 3 The rat was then still in the best condition of health, and its progress is to be followed up Similar results were obtained with other specimens of the multimammate rat

These results, which are to be consolidated by further experiments have suggested several interesting problems One is that the multimammate rat, used in this Institute for some time for many investigations on plague, cancer and bilharzia, is evidently a much better experimental animal for investigations on relapsing fever than the white mouse It may perhaps prove to be an ideal biological test-animal for silent infections in humans, where spirochætes are so rare in the blood that they cannot be detected by the usual laboratory methods

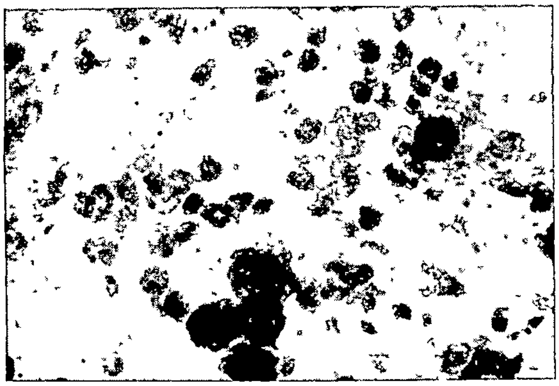

Fig 1 Blood smear of white mouse on the ninth day after subcutaneous infection with *Borrelia duttoni*

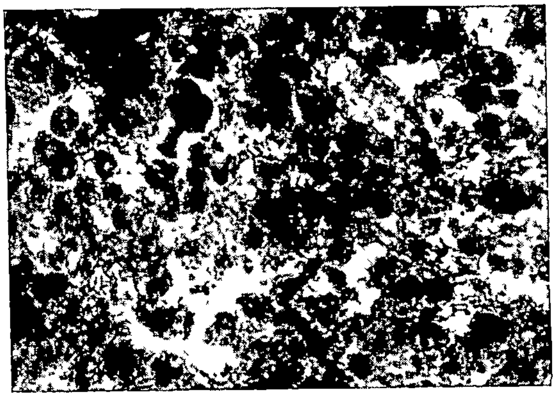

Fig 2 Blood smear of multimammate rat on the eleventh day after subcutaneous infection with *Borrelia duttoni*

Another problem is an epidemiological one It is now almost certain that the natives get their tampans from the burrows of wart-hogs All the wart-hog burrows which I have been able to check in the Bechuanaland Protectorate have been highly infested with tampans which, according to Dr G A Walton (by letter), are, with scarcely any doubt, morphologically and physiologically identical with those found in the huts in Maun and other places in the Bechuanaland Protectorate and the Northern Transvaal But the ticks collected by us from burrows in these areas, and also those collected by other authors in Central Africa, have never been found infected with *Borrelia* Further, the wart-hog itself has never been found infected and is refractory when infected experimentally (comp Geigy and Mooser[1]) Evidently the wart-hog is not a natura reservoir of African relapsing fever, and the ticks may acquire their infection from another animal Incidentally, the 'wild' *Ornithodoros moubata* from the burrows of wart-hogs can easily be infected experimentally with *Borrelia duttoni*

The multimammate rat is a wild rodent which live in close contact with man in Africa, and in the native villages it plays the same part as the house ra (*Rattus rattus*) and the Norwegian rat (*Rattus norvegicus*) in the towns in Africa and in human habitation throughout Europe and Asia Tampans brought t the huts by native hunters, for example, sooner o later come into contact with the multimammate rat there Is this rat perhaps the natural reservoir, o one of them, of *Borrelia duttoni* ? We have not ye looked for natural infections in this rat, but th experimental picture shows that it would be an idea reservoir, as it remains highly positive for a long time without its general condition of health being influenced This problem is being investigated mor thoroughly

I wish to thank Prof J F Murray and Dr B d Meillon of this Institute for their interest and help Mr D H S Davis, Medical Ecology Centre, Union Health Department, for providing the wild rodents and Drs B T Squires, B O Wilkin and E I Szlamp of the Medical Department, Bechuanalan Protectorate, for their support The photomicro graphs were prepared by Mr M Ulrich of the Photo graphic Department, South African Institute fo Medical Research

CHEMISTRY AND TAXONOMY IN THE DIPTEROCARPACEAE

By Dr E C. BATE-SMITH
Low Temperature Research Station, Cambridge

AND

Dr T C WHITMORE
Botany School, University of Cambridge

LIVING specimens of the Dipterocarpaceae are not apparently available in Great Britain, and it has so far not been possible to include them in surveys of the phenolic constituents of plants[1-3] Recently, however, through the kindness of the Director, Forest Research Institute, Kepong (Selangor), fresh leaves of twenty-eight species of dipterocarps have been received from Malaya, and these have been examined by the methods previously described (*loc cit*) The results are interesting because the species were selected from a large collection so as to be representative not only of all the available genera but also of the recognized groups of *Shorea*, the largest genus in this family, which, because of its valuable timber and other economic products, has received a great deal of attention from the forestry officers and official taxonomists in the Indomalaysian countries

Consideration of the phenolic constituents of the leaves of a large number of Dicotyledons has indicated[3] that three characters are particularly valuable from the taxonomic point of view presence or absence of leuco-anthocyanins; presence or absence of vicinal trihydroxy groupings in the phenolic constituents, and the presence or absence of the polyhydroxy and hydroxymethoxy aromatic acids, caffeic, ellagic, ferulic and sinapic acids. It is often of value also to note other constituents, not necessarily identified, which are present in some, but absent from other, species in the same or different genera, as indicators of possible relation between the species possessing them

The results of the chromatographic examination of the hydrolysates of the leaves of the 28 species are given in Table 1 The constituents recorded are, from left to right, in order of increasing R_F in aqueous acetic acid–hydrochloric acid (Forestal solvent), *M* = myricetin, *D* = delphinidin (formed from leucodelphinidin), *E* = ellagic acid, *Q* = quercetin, *Cy* = cyanidin (formed from leucocyanidin), *K* = kaempferol, *Caff* = caffeic acid, *S* = sinapic acid, *F* = ferulic acid In the last column are recorded other constituents visible in the ultra-violet, with their R_F values in Forestal solvent and their appearance in ultra-violet before and after (→) fuming in ammonia vapour The abbreviations used are *bl* = blue, *brn* = brown, *gr* = green, *V* = violet, *y* = yellow, *br* = bright, *d* = deep, *dk* = dark, *f* = faint, *l* = light, *v* = very Sinapic acid and ferulic acid are identified on a separate chromatogram run in toluene–acetic acid[4]

The genera are listed in the order given by Symington[5] The species are listed in alphabetical order within the genus, except for *Shorea* which is divided into groups according to the same author Symington considered these groups to be natural subdivisions of the genus, perhaps worthy of generic status, but was not prepared to give them definite botanical names or status until the whole genus was revised taxonomically This revision has still not been made for it awaits the collection and description of the rich Bornean dipterocarp flora Desch[6,7], working on the timbers of *Shorea*, independently established four groups based mainly on gross timber characters which correspond closely to Symington's subdivisions The groups are named *B* = balau, *Y*, *W* and *R* = yellow, white and red meranti respectively; within each there is considerable homogeneity in characters of the living trees, including the colour of the wood and sliced bark and the dead leaves

Upuna bornensis		−	−	−	−	−	−	−	−	−	*gr*, 0 79

The data in Table 1 suggest that the genera can be arranged in groups, in the first instance according to the abundance and type of the leuco-anthocyanins present *Dipterocarpus* and *Dryobalanops*, abundant with consistent *L–D*, *Shorea* (and one *Vatica* sp) less abundant, with both *L–D* and *L–Cy*, *Hopea*, *Balanocarpus*, *Anisoptera*, and two *Vatica* spp with little or no *L–A*, and *Upuna* with none of the common phenolic constituents

Dipterocarpus and *Dryobalanops* agree also in having consistent and often abundant myricetin, and no subsidiary constituents In both *Shorea* and *Hopea* many of the species have a subsidiary constituent R_F 0 68–0 7 with intensely blue fluorescence, which may or may not be the same in all species These two genera have also numerous other subsidiary constituents *Hopea*, *Balanocarpus*, and one or two *Shorea* spp also have caffeic acid, absent from the other genera All the genera except *Anisoptera* and *Upuna* have ellagic acid, *Shorea foxworthyi* having in addition (probably) gallic acid

Overall the grouping suggested is *Dipterocarpus* with *Dryobalanops*, *Shorea* with *Hopea* and *Balanocarpus*, *Vatica* rather closer to *Shorea* than to *Hopea*, *Anisoptera* and *Upuna* uncertain

The groups of *Shorea* are not very distinct, neither yellow nor white meranti have much *L–A*, and *L–D* is absent from both sections, but species in both the balau and the red meranti groups have the same constitution The nature of the pigments responsible for the colours of the sliced bark is unknown, it is not even known whether they are phenolic, so that there is no *prima facie* reason to expect that the phenolic constituents in the leaves would follow the proposed subdivision of the genus

One further point is worth making *Balanocarpus* Bedd has become a repository for all wingless fruited dipterocarps *B heimii* should probably be included in *Hopea* on floral characters[5] and wood characters[6], and now we can reach the same conclusion from the chemistry The suggested regrouping of other species is also supported by the present evidence

PLANT-GROWTH SUBSTANCES AND THE COPPER CHELATION THEORY OF THEIR MODE OF ACTION

By Dr C H FAWCETT

Agricultural Research Council Unit on Plant-Growth Substances and Systemic Fungicides,
Wye College, University of London

FOLLOWING the observations that certain compounds possessing chelate groups can exhibit significant plant growth-regulating activity[1], several workers have been trying to demonstrate the converse, namely, that highly active plant-growth regulators can react with metal ions to form chelate complexes The discovery by Cohen, Ginzburg and Heitner-Wirgum[2] that the ultra-violet absorption spectra of 3-indolylacetic acid and 1-naphthylacetic acid are profoundly altered in presence of cupric, but not calcium or magnesium ions, led them to postulate that the cupric ion reacted with the carboxyl group in these acids to form a copper complex which then formed a chelate by employing the aromatic ring as the second complexing group

After repeating their experiments using solutions obtained by dissolving cupric nitrate trihydrate in 50 per cent aqueous ethanol, I observed that with 3-indolylacetic acid the optical density of each solution in the series measured at 360 mμ did not remain constant but tended to increase slowly (cf ref 3) Since with cupric nitrate and 1-naphthylacetic acid, measured at 330 mμ, the optical density of each solution remained constant for several minutes, this system was used for comparison with the cupric nitrate/1-naphthoic acid system measured at 348 mμ It was found that the relationship between optical density and acid/copper ratio is similar for both 1-naphthylacetic acid (Fig 1) and 1-naphthoic acid Thus, the enhancement of ultra-violet absorption is not limited to the highly active 1-naphthylacetic acid but occurs also with the relatively inactive 1-naphthoic acid

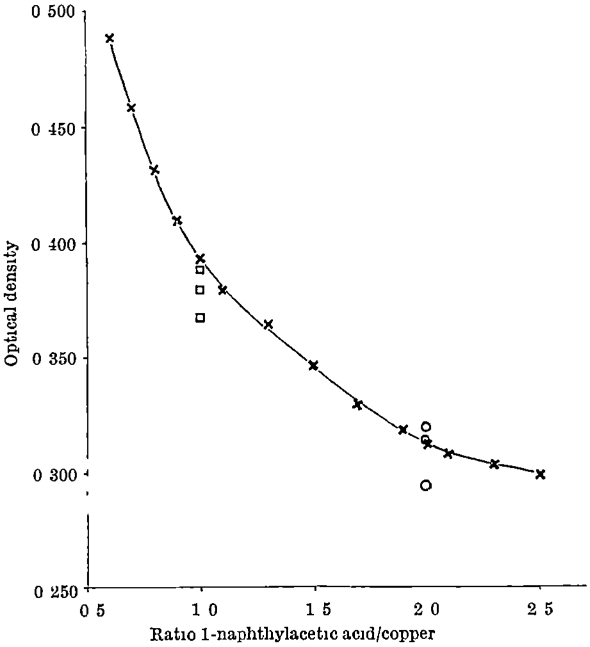

Fig 1 Optical density of copper/1-naphthylacetic acid complex (330 mμ, 1 cm cells, *p*H ~ 3 6) in 50 per cent aqueous ethanol ×, Concentration of added cupric nitrate varied as shown with concentration of 1-naphthylacetic acid constant at 2 × 10^{-2} *M*, ○, concentrations of added copper 1-naphthylacetate 10^{-2} *M* and nitric acid 2 × 10^{-2} *M*, ⊡, concentrations of added copper 1-naphthylacetate 10^{-2} *M*, nitric acid 2 × 10^{-2} *M* and cupric nitrate 10^{-2} *M*

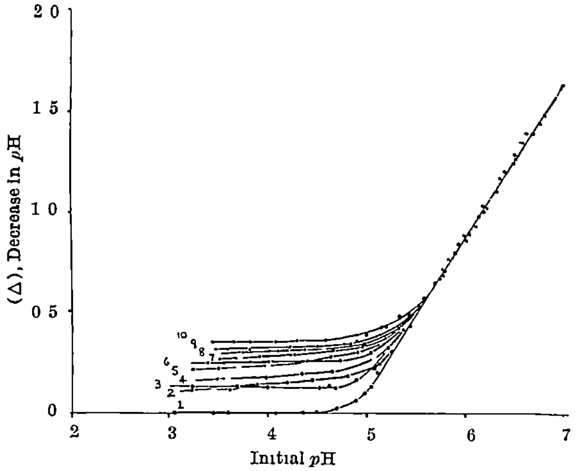

Fig. 2. The relationship between the initial pH of 50 per cent aqueous ethanol, containing the acid indicated, and the decrease in pH, (Δ), on dissolving 4·83 mgm. cupric nitrate trihydrate in 10 ml. Acids added to obtain initial pH: 1, nitric; 2, formic; 3, 2,4-dichlorophenoxyacetic; 4, 1-naphthoic; 5, succinic; 6, benzoic; 7, acetic; 8, 1-naphthylacetic; 9, 3-indolylacetic; and 10, trimethylacetic acid

The general reaction in aqueous ethanol between cupric nitrate and 1-naphthylacetic acid can be written:

$$2C_{10}H_7CH_2COOH + Cu(NO_3)_2 \overset{\text{(50 per cent aqueous ethanol)}}{\rightleftharpoons} Cu(C_{10}H_7CH_2COO)_2 + 2HNO_3$$

In writing this equation the various ionic species which may exist in solution have, for simplicity, not been characterized. For each 1-naphthylacetic acid/copper ratio the optical density of the solution at constant temperature should be independent of whether the equilibrium is attained by using reactants which give the forward reaction or reactants which give the reverse reaction. Accordingly, cupric 1-naphthylacetate was synthesized and used stoichiometrically with nitric acid in aqueous ethanol to give the reverse reaction and reconstitute the solution having a ratio 1-naphthylacetic acid/copper equal to 2·0. The optical density of this solution in which the reverse reaction had occurred was found to be identical with that of the solution containing the products of the forward reaction (Fig. 1). Furthermore, addition of cupric nitrate, sufficient to lower the 1-naphthylacetic acid/copper ratio to 1·0 in these reconstituted solutions, increased the optical density to the value found for this ratio when using the reactants of the forward reaction (see Fig. 1). Since the equilibrium may be reached from either side without adding a chelate group, it is concluded that a reaction involving chelation is not required to account for the exaltation of ultra-violet absorption given by cupric nitrate with 1-naphthylacetic acid.

By measuring the pH Cohen *et al.*[2] also confirmed that cupric nitrate reacted differently from calcium and magnesium nitrates when added to solutions of 3-indolylacetic acid and 1-naphthylacetic acid in aqueous ethanol. Furthermore, they found that while the pH of these acids in solution was lowered due to release of hydrogen ions by complexing of the copper ion with the carboxyl group, yet under the same conditions only slight complexing occurred with acetic acid or indole. The results were interpreted as evidence for the entire aromatic ring functioning as a second complexing group, thus resulting in chelate formation.

In a study using aqueous ethanol solutions of several closely related acids, comprising active and inactive growth regulators, it was found that in general the addition of cupric ions lowers the pH. Some of the results are shown in Fig. 2. The observed pH changes, however, do not correlate with plant growth-regulating activity; thus, the aromatic carboxylic acids (for example, benzoic and 1-naphthoic), and the alkanecarboxylic acids (for example, formic, acetic and trimethylacetic), which are all inactive[4] in the wheat cylinder elongation test, exhibit an effect in presence of copper ions similar to that found with highly active[4] 3-indolylacetic acid, 1-naphthylacetic acid and 2,4-dichlorophenoxyacetic acid. Furthermore, the results show no difference which would indicate the occurrence of chelation involving the aromatic ring (Fig. 2).

In the pH range studied two mechanisms of hydrogen ion formation are apparent. Mechanism I, which operates over a pH region known to be of considerable physiological importance in plant cells, produces a large effect (Δ), which is the same for all the different compounds examined (Fig. 2). It is significant that at higher initial pH values, that is, when the concentration of carboxylic acid for adjusting the pH is decreasing, the effect (Δ) obtained by adding the copper salt is increasing linearly; and when no carboxylic acid is added to the aqueous ethanol solvent the effect (Δ) is the largest throughout the pH range investigated. The results lead to the conclusion that the effect (Δ) between pH 5·4 and 7 depends upon hydrolysis and they indicate that hydrogen ion formation occurs by a reaction of the following type:

$$[Cu(H_2O)_x]^{++} \rightleftharpoons [Cu(OH)(H_2O)_{x-1}]^{+} + H^{+} \qquad (I)$$

The cupric ion is represented here as described by Orgel, and the reaction written by analogy with his example for iron[5]. On the other hand, mechanism II appears limited to the pH region below about 5·4. The effect (Δ) is smaller, different for the different structures examined, and zero for nitric acid. There appears to be a correlation between the effect (Δ) and the *pK* value of each acid and further work on this aspect is proceeding. The results suggest that hydrogen ion formation by mechanism II depends upon salt (that is, complex) formation, which,

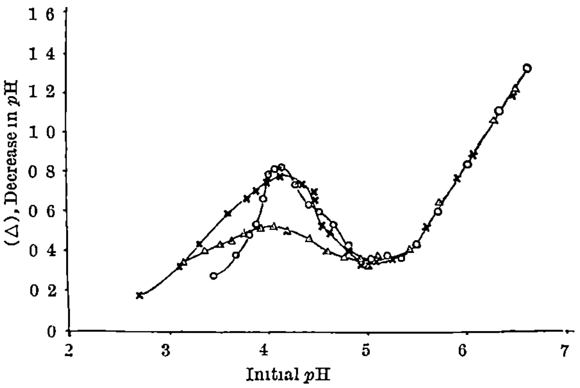

Fig. 3. The relationship between the initial pH of 50 per cent aqueous ethanol, containing the acid indicated, and the decrease in pH, (Δ), on dissolving 4·83 mgm. cupric nitrate trihydrate in 10 ml. Acids added to obtain initial pH: ○, aspartic; Δ, glycollic and ×, citric acid

ignoring hydration, can be represented by an ionic reaction of the type

$$n\mathrm{H}A + \mathrm{Cu}^{++} \rightleftharpoons \mathrm{Cu}(A)_n^{[2-n]+} + n\mathrm{H}^+ \qquad \text{(II)}$$

where HA is a weak acid and n is 1 or 2 Thus, these results from pH measurements in the region pH 3–5 4 can be interpreted by an equation which is an ionic form of the general reaction shown above to account for the results obtained by ultra-violet absorption determinations

When certain carboxylic acids (for example, glycollic, citric and aspartic) were examined, in aqueous ethanol with cupric nitrate, it was found that another operative factor could be demonstrated (see Fig 3) It is clear, therefore, that these acids which have the ability to form chelates with copper[6] exhibit behaviour different from the various plant-growth substances studied

Thus, the present evidence does not support the concept that plant-growth regulating activity is explicable in terms of chelation (cf ref 7)

I am grateful to Prof R S Nyholm and Prof R L Wain for helpful discussions

CONTROL OF ANTHERIDIUM FORMATION IN THE FERN SPECIES *ANEMIA PHYLLITIDES*

By Dr ULRICH NAF

Rockefeller Institute, New York

DÖPP[1] demonstrated that an extract from mature prothalli of *Pteridium aquilinum* hastened the onset of antheridium formation in young prothalli of this fern species by a few days and in the prothalli of *Athyrium filix-mas* by a few weeks Dopp envisaged the possibility that the promotion of antheridium formation occurred by way of unspecific growth inhibition Subsequent investigations, though, led to the conclusion that the activity of the extract must be attributed to a specific factor which controls the initiation of antheridia during the normal process of development[2,3]

An assay was devised which took advantage of the observation that the prothalli of *Onoclea sensibilis* failed to form any antheridia spontaneously under the prevailing conditions of culture but responded readily when grown on a medium containing extract of mature *Pteridium* prothalli Conditions were further defined under which the extract from seven-week-old prothalli of *P aquilinum* was active to a dilution of 1 30,000 This increased the activity obtained by Dopp by a factor of about 300 Under these same conditions of culture the active substance accumulated to almost as high an activity in the medium[2]

While the prothalli of both *O sensibilis* and *P aquilinum* responded readily to the active factor at young stages of development, they lost their responsiveness soon after they assumed heart shape and a few days prior to attaining the archegonial phase Once insensitive, the prothalli failed to form antheridia even if supplied with the factor at a concentration 15,000 times higher than that sufficient to induce antheridia in prothalli just a few days younger[3]

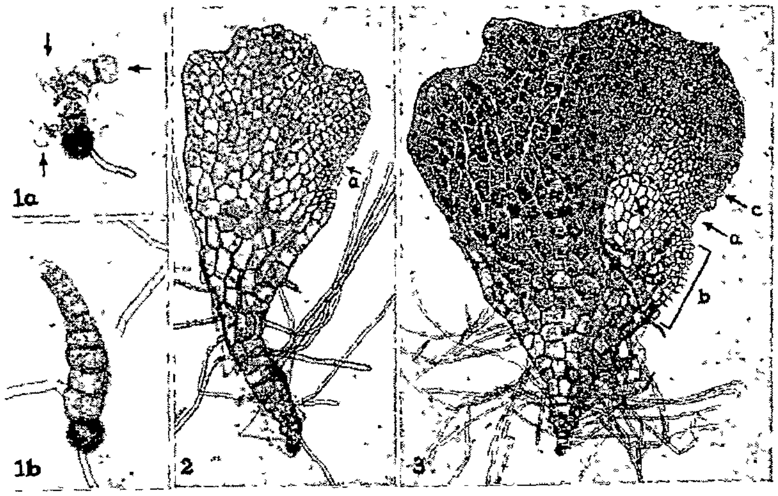
Work on the activity spectrum of this factor disclosed that it was active toward the representatives tested of seven out of nine sub-groups of the family Polypodiaceae listed by Eames[4] the asplenioids, pteroids[1], onocleoids, blechnoids, dryopteroids[2], gymnogrammoids[5] and toward *Woodsia obtusa*, a representative of the sub-group woodsioids (unpublished information) Among non-polypodiaceous species, only *Dennstaedtia punctilobula* (Dicksoniaceae) was found to be responsive The substance failed to promote antheridium formation even at the highest available concentration (half full-strength *Pteridium* medium that was active toward the prothalli of *O sensibilis* to a dilution of 1 30,000) in the following fern species *Polypodium aureum* (Polypodiaceae), *Lygodium japonicum*, *Anemia phyllitides* (Schizaeaceae), *Osmunda claytonia* and *O cinnamomea* (Osmundaceae)

The present account deals with the control of antheridium formation in *Anemia phyllitides*, one of these unresponsive fern species

The procedures used in the sterilization and inoculation of the spores have been described elsewhere[3] A detailed description of the conditions of culture and of the medium which contains the inorganic salts used by Moore[6] is given in the same report Hoagland's earlier used *A–Z* solution of micro-elements was replaced with a Hoagland trace element solution of simpler composition (mgm /l of medium boric acid, 2 86, manganese chloride ($\mathrm{MnCl_2\ 4H_2O}$), 1 81, zinc sulphate ($\mathrm{ZnSO_4\ 7H_2O}$), 0 22, molybdenum trioxide, 0 07, copper sulphate ($\mathrm{CuSO_4\ 5H_2O}$), 0 08) Iron was added as ferric tartrate The prothalli were cultured in 125-ml flasks containing 33 ml of medium or in 50-ml flasks with 12 ml of nutrient Unless stated otherwise, the media were solidified with 1 per cent agar

It was observed that prothalli of *Anemia phyllitides* formed antheridia at a very early stage of development, while they were still at the filamentous phase, if the spores were inoculated on 35–50-day-old gametophyte cultures of the same fern species Prothalli superinoculated on 30-day-old cultures attained the antheridial phase somewhat later, although still many days prior to the control prothalli

In a subsequent experiment a single 50-day-old gametophyte of *Anemia phyllitides* was placed on the agar surface at one side of a seven-day-old culture of this same species in 125-ml flasks Observations at



Figs 1–3 (Fig 1*a* and *b*, × 62, Fig 2, × 27 5, Fig 3, × 20)

daily intervals disclosed that young prothalli with antheridium initials could be detected within 3–4 days in the immediate proximity of the mature prothallus 7–8 days following the introduction of the mature gametophyte at the side of the flasks, young antheridium-bearing prothalli could be first observed in the centre, and 12–14 days after its introduction at the opposite side of the flask 8–10 further days elapsed before antheridium initials appeared in the control cultures The above observations suggested that, as the prothalli of *A phyllitides* reached a certain stage of development, they began to elaborate, and to secrete into the medium, a substance controlling the induction of antheridia This hypothesis gained in likelihood when medium that had supported the growth of *Anemia* prothalli was assayed for antheridium-inducing activity The assays were conducted by inoculating spores of *A. phyllitides* on fresh nutrient medium which contained the medium of the *Anemia* cultures at a dilution series with a dilution factor of approximately 3 (1/3, 1/10, 1/30, 1/100,) 50-ml flasks which contained 12 ml of medium were used The assays were read 18 days after inoculation, 11–12 days prior to the onset of spontaneous antheridium formation Medium of 29-day-old or younger cultures was regularly inactive even at 1/3 full strength, the highest concentration of *Anemia* medium tested On the other hand, the medium of 39-day-old cultures induced antheridia to a dilution of 1 30, the medium of 49- and 59-day-old cultures to a dilution of 1 100 (occasionally 1 300), and 1 300, respectively The same activity was encountered in liquid and agar-solidified media Whereas the lowest effective concentration of *Anemia* medium brought about antheridium formation in only 1 out of 4–20 prothalli, the percentage of responding prothalli rose to 100 as the concentration of the active factor was increased by a factor of 3–10 Antheridium initials could be first discerned about 9 days after the spores were inoculated (the bulk of the spores germinated between 3 and 5 days following inoculation) It was further noticed that activity could be regularly detected at a concentration lower by a factor of about 3 if the assay was read 18 instead of 12 days following inoculation The reason for this remains to be explored Fig 1*a* shows a 12-day-old *Anemia* prothallus with 3 antheridia (see arrows) which were initiated in response to 1/30 full strength *Anemia* medium (active to a dilution of 1 300), while control prothalli in cultures of the same age (Fig 1*b*) and even in 25-day-old cultures (Fig 2) were invariably free of antheridia

Figs 2 and 3 show further that the maturing prothallus has a lateral meristem (arrow *a*), a phenomenon encountered in only a few fern species[7] The first spontaneously formed antheridium, which would probably have arisen on the prothallus pictured in Fig 2 in about 4–5 days, is invariably initiated from a marginal cell a short distance behind the meristematic initial Marginal cells afterwards cut off by the meristematic initial toward the base of the prothallus also give rise to antheridia so that ultimately a whole row of them can be seen (marked *b* in the 35-day-old prothallus of Fig 3) In contrast, the marginal cells cut off by the initial toward the tip of the prothallus fail to form antheridia even in the presence of added *Anemia* factor Instead, some of them give rise to hook-shaped hairs (Fig 3, arrow *c*) Once the first antheridium initial has been formed marginally, others arise on cells inside the prothallus (3 of about 18 such antheridia are indicated by arrows)

The area of spontaneous antheridium formation always remains restricted, however Thus, antheridia never arise in the part of the prothallus anterior to the lateral meristem Again, the zone of antheridium formation in the posterior region does not stretch across the whole prothallus , instead, it extends about halfway or less inside the prothallus from the margin of the cell plate which bears the lateral meristem (the zone is marked by a black broken line on Fig 3) The other half of the posterior region remains free of antheridia except for the occasional occurrence of 1–3 antheridia in marginal cells

Observations following the application of the active substance to cultures of various ages showed that young prothalli responded with antheridium formation throughout most of their body As the age of the prothalli increased, the responding area gradually contracted to that described for spontaneous antheridium formation The loss of sensitivity in the anterior part of the prothallus preceded the contraction in the responsive area of its posterior region

Information was obtained concerning the time lag between the application of the active substance and the first detection of antheridium initials Liquid medium of 50-day-old *Anemia* cultures (active to 1 300) was applied to 12-day-old and to 18-day-old *Anemia* cultures which were grown in 50-ml flasks containing 12 ml of agar-solidified nutrient $\frac{1}{2}$ ml of the *Anemia* medium was applied to each flask, to some at full strength, to others at dilutions of $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$ and 1/16 The control cultures received an equal amount of fresh medium Antheridium initials (semicircular outgrowths of vegetative cells that were not as yet cut off by a cell wall) first appeared between 1 and $1\frac{1}{2}$ days following the application of the active substance and in the 18-day-old cultures In contrast, the appearance of antheridium initials in both 6- and 9-day-old prothalli of

O sensibilis followed the application of the *Pteridium* factor with a delay of between 2½ and 3 days at all tested concentrations

The first-formed *Anemia* initials attained the four-cell stage, that is, the number of cells contained by mature antheridia, between 3½ and 4 days after the active substance was applied No difference could be detected between the rates at which the first-formed antheridium initials attained the four-celled stage over the applied range of concentrations On the other hand, an increase from 1/16 to ½ full strength of the added *Anemia* medium increased the proportion of responding prothalli from about 15 to 100 per cent If the *Anemia* factor was supplied to 5-day-old prothalli which comprised a maximum of 3 green vegetative cells, then between 3 and 3½ days elapsed before the first antheridium initials could be seen, that is, about 2 days more than in both the 12-day-old and the 18-day-old prothalli It thus appears that the events leading to the appearance of antheridium initials proceed more slowly in very young prothalli Alternatively, the very young prothalli may lack competence to respond to the active factor

As indicated above, the *Pteridium* factor brings about antheridium formation in a large number of fern species It should also be emphasized, though, that the minimally effective concentrations vary so widely that the prothalli of some species (for example, *Dennstaedtia punctilobula*) must be supplied with that factor at a concentration more than a hundred times higher than those of other species (for example, *Onoclea sensibilis*) The possibility must thus be considered that the induction of antheridia in *O sensibilis* and in *A phyllitides* is controlled by the same factor at different ranges of effective concentrations *Pteridium* medium (active toward the prothalli of *O sensibilis* to a dilution of 1 30,000) was inactive toward the prothalli of *A phyllitides* at all concentrations which, with a dilution factor of 3, ranged from ⅓ to 1/100,000 full strength In turn, the prothalli of *O sensibilis* were unresponsive toward *Anemia* medium (active toward the prothalli of *A phyllitides* to a dilution of 1 300) at all dilutions which ranged again from ⅓ to 1/100,000 full strength

It is, therefore, difficult to avoid the conclusion that the induction of antheridia in *A phyllitides* and in *O sensibilis* is controlled by chemically distinct substances This conclusion receives support from the demonstration that the antheridium-inducing activity of the *Anemia* medium is stable to boiling for 10 min at *p*H 12, while the *Pteridium* factor was labile under those conditions[2] The antheridium-inducing activity of the *Anemia* medium was further found to be stable to boiling for 10 min at *p*H 2 and to autoclaving at *p*H 5 4, the *p*H of the culture medium , it was destroyed upon ashing and adsorbed on charcoal The latter properties are similar to those of the *Pteridium* factor[2]

The *Anemia* factor failed to promote antheridium formation in prothalli of *Osmunda claytonia* (checked 15 days after inoculation, 2 days prior to the onset of spontaneous antheridium formation), which were also unresponsive to the *Pteridium* factor The prothalli of *Lygodium japonicum*, another species unresponsive toward the *Pteridium* factor, were shown to elaborate, and to secrete into the medium, a substance which greatly hastens the onset of the antheridial phase in this fern species which, like *A phyllitides*, belongs to the family Schizaeaceae Preliminary investigations indicate that this substance is chemically distinct both from the *Pteridium* factor and from the *Anemia* factor

It is apparent from these studies that antheridium formation is controlled by different substances in different groups of ferns It should also be recalled that within the wide range of species responsive to the *Pteridium* factor, the minimally effective concentrations vary widely Thus, the prothalli of *Dennstaedtia punctilobula* failed to respond unless they were supplied with the *Pteridium* factor at a concentration about 125 times higher than was necessary to induce antheridia in prothalli of *O sensibilis* In the prothalli of *Woodsia obtusa* the minimally effective concentration of the *Pteridium* factor exceeded that required for antheridium formation in the prothalli of *O sensibilis* by a factor of about 25 The possibility must therefore be considered that the factors controlling antheridium formation in these species are actually different but structurally so closely related that the factor produced by *P aquilinum* is capable of bringing about antheridium formation also in *Dennstaedtia punctilobula* and in *Woodsia obtusa* if it is supplied at a high enough concentration Raper[8] also considers the possibility that hormonal specificities account for the failure to obtain oospores in some of the attempted inter-species and intergeneric crosses of water moulds

The above results raise a question of biological specificity The work of Kluyver and Van Niel has directed attention to the similarity, even identity, of many basic biochemical patterns in taxonomically widely separated organisms It is tempting to postulate that the metabolism associated with antheridium formation, an event that we conceive of mainly in morphological terms, is also similar in different fern species The above results may be reconciled with such a postulate if we consider that the induction of an antheridium is likely to involve many reactions and compounds Antheridium formation in *P aquilinum* might thus be controlled by a different factor than in *A phyllitides* because a different reaction became rate-limiting during evolution Alternatively, we might be witness to evolution on a molecular level On this assumption the *inducing* molecule has undergone a gradual structural modification probably concomitantly with changes in a receptor molecule The isolation and characterization of the two substances should yield pertinent information In the meantime, an attempt is being made to assay for similarity between the two factors based on the postulate that one factor might be a precursor of the other or that one factor might behave as a chemical analogue of the other and thus interfer with its synthesis or with the function it perform in the initiation of antheridia

I am grateful to Dr Armin C Braun for th encouragement he has given this investigation an for a critical reading of the manuscript I am als indebted to Drs Ralph H Wetmore and Max War for supplying plants and spores of *A phyllitides*

This investigation was supported in part by National Science Foundation Research Grant (*G*-3225

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, November 2

Institution of Electrical Engineers, Electronics and Communications Section (at Savoy Place, London, W C 2), at 5 30 p m —Dr A E Karbowiak "Some Comments on the Classification of Waveguides Modes", Mr L Lewin "Some Comments on Quasi-Optical Methods at Millimetre Wave-lengths"

University of London (at the School of Oriental and African Studies, London, W C 1), at 5 30 p m —Prof A de Almeida (Lisbon) "Mucuepes—a Native People from the Moçâmedes Desert" (First of three lectures on "The Non-Bantu Peoples from Angola" Further Lectures on November 3 and 5)*

Society of Chemical Industry, London Section (at 14 Belgrave Square, London, S W 1), at 6 30 p m —Dr Otto Horn "Chemical Research in Germany"

Tuesday, November 3

University of London (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 1 15 p m —Mr N J B Plomley "The Tasmanians an Extinct Race" *

Institution of Electrical Engineers, Measurement and Control Section (at Savoy Place, London, W C 2), at 5 30 p m —Mr P Gleghorn "An Analogue Electronic Multiplier using Transistors as Square-Wave Modulators"

University of London (at Imperial College of Science and Technology, London, S W 7), at 5 30 p m —Prof E C Cherry "Telecommunication as Social Science" (Inaugural Lecture)

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m —Dr J M Mitchison "The Life Cycle of Growing Cells" (Sixth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation Further lectures on November 5, 10, 12, 17, 19, December 1, 3, 8, 10)

Plastics Institute (at the Wellcome Building, 183–193 Euston Road, London, N W 1), at 6 30 p m —Dr W F Watson "Recent Advances in Synthetic Rubbers"

Society of Chemical Industry, Plastics and Polymer Group (at 14 Belgrave Square, London, S W 1), at 6 30 p m —Dr G F C Barrett " 'Delrin' Acetal Resin"

Textile Institute (at the Chemical Society, Burlington House, Piccadilly, London, W 1), at 6 30 p m —Mr J David "Modern Proofing"

Wednesday, November 4

British Institution of Radio Engineers (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 3 p m and 6 p m —Half-day Symposium on "Input/Output Devices"

Institute of Petroleum (at 61 New Cavendish Street, London, W 1), at 5 30 p m —Mr W S Ault "Oil and Transport"

Royal Meteorological Society (at 49 Cromwell Road, London S W 7), at 5 30 p m —Mr H Charnock "Ocean Currents"

Society for Analytical Chemistry (at the Chemical Society, Burlington House, Piccadilly, London, W 1), at 7 p m —Meeting for reading of Original Papers

Thursday, November 5

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W 12), at 4 p m —Dr T Alper Dr M Ebert and Dr R H Thomlinson "Biological Effects of Radiation—General Survey" (First of six lectures Further lectures on November 12, 19, 26, December 3 and 10)*

Royal Society (at Burlington House, Piccadilly, London, W 1), at 30 p m —Prof A V Hill, F R S , and Mr J V Howarth "The Reversal of Chemical Reactions in Contracting Muscle During n Applied Stretch", Mr F W Darwin and Dr J W S Pringle, F R S "The Physiology of Insect Fibrillar Muscle 1 Anatomy and nnervation of the Basalar Muscle of Lamellicorn Beetles", Mr C E Machin and Dr J W S Pringle, F R S "The Physiology f Insect Fibrillar Muscle 2 Mechanical Properties of a Beetle Flight Muscle"

University of London (in the Physiology Theatre, University ollege, Gower Street, London, W C 1), at 5 p m —Dr P N Campbell The Synthesis of Protein by the Cytoplasmic Components of Animal ells" (First of three lectures Further lectures on November 12 nd 19)*

Institution of Electrical Engineers (at Savoy Place, London, W C 2), at 5 30 p m —Mr M C Crowley-Milling "The Application of Irradiation in Industry"

University of London (at the London School of Hygiene and ropical Medicine, Keppel Street, Gower Street, London, W C 1), at 30 p m —Prof G Pontecorvo "Genetic Analysis via Somatic Cells" (Seventh of fifteen lectures on "The Scientific Basis of Medine" organized by the British Postgraduate Medical Federation urther lectures on November 10, 12, 17, 19, December 1, 3, 8, 10)*

Society of Chemical Industry, Microbiology Group (joint eeting with the Agriculture Group, at 14 Belgrave Square, London, W 1), at 6 15 p m —Dr M E Brown "Plant Roots and Soil Micro-Organisms", Dr R M Jackson "The Ecological Significance of the Rhizosphere"

Friday, November 6

Institute of Physics (at 47 Belgrave Square, London, S W 1), at 6 p m —Mr R D Moore "The Role of Physics in the Investigation and Treatment of Heart Disease"

Society of Dyers and Colourists (at the Royal Society, Burlington House, Piccadilly, London, W 1), at 6 p m —Mr D F Anstead "The Use of Colour in Cosmetics"

Society of Chemical Industry, Fine Chemicals Group (at 14 Belgrave Square, London, S W 1), at 6 30 p m —Dr B C L Weedon "Electrolytic Methods in Preparative Organic Chemistry"

Royal Institution (at 21 Albemarle Street, London, W 1), at 9 p m —Prof H Bondi, F R S "What Goes On Inside the Stars"

Saturday, November 7

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S E 23), at 3 30 p m —Mr B B Boycott "Devilfish—Octopuses, Squids and Cuttlefishes" *

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Director and an Assistant Director of the British Institute of History and Archæology in East Africa (Headquarters at Dar es Salaam and Kampala)—The Secretary, The British Academy, Burlington House, Piccadilly, London, W 1 (November 10)

Lecturer (preferably with special experience in the field of organic chemistry) in Chemistry at Victoria University of Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (New Zealand, November 15)

Imperial Chemical Industries Fellow (preferably under 29 years of age) at Durham or Newcastle for research in Engineering, Chemistry, Physics and allied subjects, including the biological application of chemistry—The Registrar, University Office, 46 North Bailey, Durham (November 16)

Plant Physiologist (honours graduate in science or agricultural science (or equivalent) with some years relevant postgraduate research experience) at the Irrigation Research Station, C S I R O , Griffith, New South Wales, Australia, to investigate effect of water stress in plants in new laboratories containing controlled environment chambers —Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W C 2, quoting Appointment No 500/115 (November 20)

Mullard Research Fellow (preferably with a Ph D degree or equivalent research experience) in Physics for research in various branches of solid-state physics, with particular reference to defects, semiconductor or surface properties—The Registrar, University College of North Staffordshire, Keele, Staffs (November 30)

Principal (with high academic qualifications, wide experience in administration, and conversant with developments in technological education)—The Clerk to the Governing Body, Battersea College of Technology, London, S W 11 (November 30)

Senior Lecturer in Physical Chemistry in the Department of Chemistry and Chemical Engineering—Prof F Sebba, Professor of Physical Chemistry, University of the Witwatersrand, Milner Park, Johannesburg, South Africa (November 30)

Lecturer in Theoretical Physics, and a Lecturer in Physics —The Registrar (Room 22, O R B) The University, Reading (December 7)

CONFERENCES: BIG OR SMALL?

MORE science means more information, in the form of books, journals and conferences No scientist needs to be reminded of this It was estimated recently that to keep up with all the current work a physiologist would have to read nearly four hundred papers a day, Sir George Thomson has even gone so far as to suggest that it is the impossibility of absorbing the necessary information that will ultimately halt scientific progress Communication is therefore a subject that we cannot afford to neglect The purposes of books and journals are, or should be, obvious, but the functions of conferences are more complicated

Scientific conferences grew as an answer to the problem of assimilating in a reasonable time the vast quantities of information scattered throughout the journals They do provide an answer—the meeting together of workers in similar fields and the collection of their ideas are the obvious advantages But is it the best answer? The basis of a conference is the presentation of papers, but why bother to read them? The distribution of all the papers to all the members would serve the same purpose It would even have advantages it is much easier to read a foreign language than to follow it by ear, and it is difficult to grasp a complicated argument at a single hearing In fact, something of the sort often happens when preprints are issued or when the proceedings are published in book form afterwards

The preprint was introduced to save time If all his audience are armed with his complete paper, there is no need for a speaker to give more than a summary This frees time for discussion or, more frequently, more papers. But the possibility of discussion is the great advantage of conferences Questions can be asked and suggestions made in print, but it is a very slow business and what takes months in the journals may take only minutes in the conference room Conferences have other advantages, of course Meeting other workers in one's own field is an obvious one But this is really an extension of the main advantage one meets in order to discuss

Conferences are getting bigger The Fourth International Congress of Biochemistry held in Vienna last September was attended by nearly five thousand scientists and the published proceedings run to fifteen volumes Two thousand one hundred papers were submitted at the Second Geneva Conference on the Peaceful Uses of Atomic Energy, and there are thirty-three volumes of proceedings These two examples are exceptions, but they do represent a real trend, at least in international conferences The question is whether this trend is a good thing Are bigger conferences necessarily better? In particular, are they better with regard to the advantages that conferences have over other methods of communication? The answer is, surely, no It has already been pointed out that the great asset of conferences is discussion, and the value of a discussion is usually inversely proportional to the size of the group There is such a press of papers that it is difficult to find time to read them, let alone discuss them Furthermore, most big conferences have to split up into sections which meet at the same time, and so it is impossible for an active member of a section to get any idea of the conference as a whole 'Interdisciplinary cross-fertilization', as it is unhappily called, does not take place

Fortunately, many people are aware of these points, in particular, some of the research foundations, such as the Ciba Foundation in Britain which recently celebrated its tenth anniversary, and the Josiah Macy Jr Foundation in the United States, deserve mention Both these organizations sponsor symposia Membership of a symposium is restricted to a small number of experts, so that profitable discussions are possible Afterwards, the complete proceedings are published It is a pity that there are so few institutions of this type interested in the physical sciences, most of them are biological, with a bias towards medicine

The Gordon Research Conferences, many of which are held every year in the United States, illustrate yet another approach They cover both the physical and biological sciences, and the membership of any one conference is restricted to a hundred They are "intended as a means of disseminating information which otherwise would not be realized through the normal channels of publication and scientific meetings" They differ from other conferences in that nothing is published, and no information may be disclosed without the speaker's consent At first this may seem odd in connexion with a conference "intended as a means of disseminating scientific information", but it enables those present to speculate freely without feeling that hundreds of critical readers will later censure them for making suggestions not backed up by adequate evidence Speculation is a vital part of science, so it is desirable that there should be some means whereby people can do so together, as well as alone A series of meetings of the Gordon type has recently been established in Britain The first Miller conference*, on radiation chemistry, was held at Portmeirion in North Wales during April 20–24 and was a success The conferences have been named after the late Dr N Miller, of the University of Edinburgh, who did much to help establish them

Big conferences are obviously here to stay. Many important aspects of them have not been discussed here, such as their significance as social events which promote international understanding, though it is to be hoped that the tendency to compete for national prestige, evident at some recent conferences, will not have the opposite effect Nevertheless, the small informal gathering, where ideas are exchanged as freely as facts, should not be neglected

---

* Further information about the Miller conferences can be obtained from the chairman of the next meeting, which is to be held in 1961—Prof F S Dainton, School of Chemistry, The University, Leeds 2

HISTORY OF COSMOLOGY

Le Système du Monde

Histoire des Doctrines Cosmologiques de Platon à Copernic. Tome 10. Par Prof. Pierre Duhem. Pp. 528. (Paris: Hermann, 1959.) n.p.

THE great work of the late French historian of science, Pierre Duhem, on the history of cosmology from Plato to Copernicus, is now completed by the publication of Volumes 9 and 10. It will be remembered that only the first five volumes were published during the author's life in the years 1914–17. At the time there was no possibility of publishing the extant material for the remaining volumes, and it seemed that the historians of science would have to become resigned to the valuable work remaining a torso for ever. However, after the Second World War circumstances were ameliorated and so the rather rare situation could arise of the missing volumes appearing some forty years after the beginning of publication. On a previous occasion comment has been made upon the unavoidable drawback of the work becoming somewhat antiquated in the meantime. This, however, is only a slight disadvantage in comparison to the immense value to be attributed to Duhem's pioneering work, which forms the beginning of the modern interest in medieval natural science.

Of the new volumes, Volume 9 brings to completion the subject-matter of Volumes 7 and 8, mainly consisting of the Parisian physics of the fourteenth century. First, the theory of the tides is dealt with from William of Auvergne to Pierre d'Ailly; then follows the equilibrium of the Earth and the oceans, with an introduction to the idea of their centre of gravity of Greek and Arab commentators of Aristotle; the origins of geology, including the theory of the small movements of the Earth. Hereafter the important question of the rotation of the Earth is tackled, the discussion of which was inaugurated by Duhem in 1909 in his epoch-making article on Oresme as a precursor of Copernicus, in the *Revue Générale des Sciences*. This article is substantially reproduced here and is supplemented by a discussion of the views of that other great figure of medieval physics, Jean Buridan. The author repeats his former conclusion that the daily rotation of the Earth was duly discussed in the Parisian school of the fourteenth century and that in particular Oresme deserves credit for his anticipation of the ideas of Copernicus on the Earth's daily rotation. In the final chapter of Volume 9 the problems of the plurality of worlds in connexion with the possibility of the vacuum and with the variability of gravity with the distance to the centre of the world are discussed.

In Volume 10 it becomes quite clear that it is not offered to us as a complete work, but only as a compilation of fragments in greater or lesser degree of perfection. The title of the whole of Volume 10 was not chosen by Duhem himself but was added by the editors, who hoped to sum up by it the principal contents of the volume. It announces a treatment of fifteenth-century cosmology and of the schools and universities in which it was developed. The decline of the University of Paris in the first half of the fifteenth century is dealt with rather elaborately, but the treatment of the subsequent developments leaves something to be desired. The German universities of that century receive full attention, but the English and Italian ones remain somewhat in the background, although Paul of Venice (Paolo Nicoletti) has an extensive chapter devoted to him. This is also the case of Nicolaus of Cusa, the German cardinal, whose ideas are expounded at length. Finally, there are chapters on the Viennese astronomers Peurbach and Regiomontanus and on the fourteenth-century humanists Petrarca and L. Bruni, which, however, are far from dealing exhaustively with the relation of humanism to medieval philosophy.

The treatment is everywhere extremely clear and interesting; one regrets that the work was not completed by its author. E. J. DIJKSTERHUIS

RUSSIAN VIEW OF SPACE FLIGHT

Sputniks and After

By Karl Gilzin. Translated from the Russian by Pauline Rose. Pp. 285+25 photographs. (London: Macdonald and Co. (Publishers), Ltd., 1959.) 21s. net.

KARL GILZIN, a lecturer at the Moscow Aviation Institute, gives here a popular account of the past present and probable future of space flight. Brooding over the whole story is the spirit of Tsiolkovski, the 'father of astronautics', who foresaw in remarkable detail the techniques likely to prove most efficacious in space flight. Since British and American authors have scarcely done justice to this Russian pioneer, the eulogy in the present book will do no harm. It also serves to remind us how the Russians have created around the name of Tsiolkovski as patron saint, a mystique of space flight which is unparalleled in the Western world: it is no accident that experiments with animals, a necessary prelude to manned space travel, have figured so largely in the Soviet rocke and satellite programmes, or that *Sputnik* 1 was launched within a month of the centenary of Tsiolkovski's birth.

The subject-matter of the book can be divided into three sections, past, present and future. The first section expounds the principles of space flight and traces the development of rockets and other powe units in fair detail, though with a pro-Russian bias: Tsiolkovski figures in the history of the gas-turbine engine, but not Whittle. The second section, covering present developments, though it includes a good chapter on the atmosphere, is disappointing in detail: there is no new information on the Sputniks, and the meagre report of the results obtained from them (which appears to date from mid-1958) is, a little surprisingly, based largely on British radio observations reported in *Nature*. The last section is an excellent preview of space flight, which ends with an imaginary but realistic excursion to the Moon by a party of school-children.

The material is presented in an easy, expert manne and the book is well illustrated and technically reliable. There are a number of lapses and inconsistencies, however: for example, the rocket o *Sputnik* 1 is on p. 117 said to have completed its 900th circuit of the Earth on December 2, 1957 when it really came down on the previous day, as i implied on p. 131; on p. 139 Jodrell Bank is describe as an Irish radio observatory, a peccadillo startling t parochial ears; and the last paragraph on p. 10 does not follow from the one before.

The translation is competent, but too overloade with abstract nouns to be called graceful, and th phraseology sometimes conflicts with establishe usage: 'thrust' sometimes masquerades as 'traction' and 'solid fuel' as 'dry fuel'. D. G. KING-HELE

VAPOUR–LIQUID EQUILIBRIUM TREATISE

apour–Liquid Equilibrium
y Eduard Hala, Jiří Pick, Vojtěch Fried and takar Vilím Translated by G Standart (Czecho-ovak Academy of Sciences Monographs and Source aterial Chemical Section) Pp xviii+402 (London nd New York Pergamon Press, 1958) 90*s* net

THE authors have made an effort to produce a comprehensive treatise on all aspects of vapour–quid equilibrium, and certainly this is the most omplete work yet to appear on the subject It is ivided into three parts, covering respectively the hermodynamic basis for correlation of data, experi- ental techniques of measurement, and an up-to-date urvey of the relevant literature The theoretical asis of the subject is developed in four chapters, arting with general thermodynamic relations in the st chapter, introducing the concept of ideal solutions the second, and finally dealing with real solutions the third and fourth

Although the content of Chapter 1 may be found in ny text-book on thermodynamics, and will be con-dered elementary by most readers, it is useful to ave such a summary of the relations to hand, and it lso serves to introduce the symbols and nomen-ature—we learn, for example, that the Gibbs free ergy is to be referred to as the "free enthalpy". is a pity that the chapter should be marred by the mmon student's error made in passing from expres-ons involving "number of moles" to those involving ole fraction" In spite of the warning at the foot page 10, the authors themselves fall into the trap n page 11 in obtaining equation I–47 The same ror is made later in the first expression of equation -255 on page 70, while equation I–257 on the same ge is not deducible from equation I–148, but ther follows directly from equation I–147 In a milar way, equation I–141 on page 28 is in fact rrect, and is not obtained, as stated, from the roneous equation I–47 In all these cases, con-sion would be avoided if the complete set of variables volved were given for each equation, rather than nply indicating the constancy of pressure and mperature In Chapter 2, the properties of ideal lutions are adequately dealt with, and Chapter 3 troduces the concepts of activity and activity co-icient, and develops the relevant thermodynamic lations The major part of Chapter 4 is concerned th integrations of the Gibbs–Duhem equation, and is is probably the most valuable section of the ole book The treatment is systematized in the y first presented by Wohl, and forms an excellent mmary of the many empirical relations now isting, including those due to Van Laar, Margules, atchard and Hamer, and Redlich and Kister It is pity that Wohl's own contribution is represented ly by his earlier work, and that no mention is ade of his 1953 paper The value of this section is hanced by the inclusion of many worked numerical amples of the application of these equations, to-ther with comparisons of the results with direct perimental data, as well as a summarized presenta-on of all the relations in tabular form Thus, hough the authors have wisely refrained from tempting a general assessment of the relative lues of these relations, they have made it easy r the reader to make his own comparisons for any ecific case

The authors show good practical sense in following up this survey with a discussion of methods for deriving complete equilibrium data from indirect measurements, again fully supported by numerical examples Here one could perhaps wish for a little more discussion on the relative suitability of the methods for numerical solution of these particular differential equations, since two methods have been introduced somewhat arbitrarily in the examples. Some discussion of the magnitude of the errors involved in the different methods would also be welcome On reading this chapter, one is left with the impression that, since the Gibbs–Duhem equation is obeyed, all the correlations are at least thermodynamically consistent The limitation of the Gibbs–Duhem equation, as an expression of variation with composition of a single phase at constant pressure and temperature, is explicitly stated in the earlier chapters However, as is frequently done, it is later assumed in some applications to hold along the equilibrium line, which for binary mixtures must involve variation of either temperature or pressure It is only fair to the authors to say that in each case this assumption is noted, but its significance and the approximation involved are rarely sufficiently stressed, and are more often glossed over, as in the case of the derivation of the expressions for limiting relative volatilities on page 45

In view of the detailed treatment accorded to these integrations of the Gibbs–Duhem equation, it is disappointing to find only a cursory treatment of alternative methods of correlating equilibrium data. The effect of non-ideality of the vapour phase is disposed of in less than eight pages, which also contain the only reference to equilibrium-ratios, or K-values Surely the Benedict equation, and all that arises from it, is worth more than a passing reference ? The law of corresponding states is illustrated by two numerical examples, but the treatment is wholly inadequate The reader will find no mention of the 'convergence-pressure' concept, nor indeed is any indication given of the difficulties arising in correlating equilibrium data when the temperature is above the critical temperature of one or more of the components Here the absence of vapour pressure makes impossible the application of the Gibbs–Duhem integrations, or even the ideal solution laws

Part 2 is concerned with laboratory techniques, and should be considered as a review of a wide range of techniques, rather than as a detailed discussion and assessment of the different methods The five chapters cover criteria of purity, temperature and pressure measurement, vapour pressure and vapour–liquid equilibrium determinations In each case a good variety of techniques is presented, and, although there is seldom an adequate assessment of precision and the treatment is sometimes superficial—for example, the dead-weight piston pressure-balance is dealt with in six lines—there are usually sufficient references to the literature to enable one to obtain all the information required

The authors state in their preface that they have deliberately avoided description of current laboratory equipment, and on these grounds have excluded thermostats This does not seem logical for a book which includes chapters on measurement of temperature and pressure and discusses manostats in some detail One cannot deny the usefulness of these in directing attention to points which so many workers overlook, and in view of the authoritative treatment of methods of determination of vapour pressure and equilibrium compositions one feels that the authors would have much to contribute on the special problems connected with thermostats Many readers will be grateful for the extensive review of equilibrium stills, particularly because of the systematic method of classification employed, and the summarized comparison of them in a single table at the end of the chapter

Part 3 consists of an alphabetical index to more than 1,200 references to original work on the experimental determination of equilibrium data This impressive list is all the more valuable as it gives world-wide coverage of technical publications up to February 1957

Although the book falls short of a comprehensive treatise and in its present edition has a number of shortcomings, it is nevertheless an outstanding contribution to the subject, and contains so much of solid worth that most workers in the field should learn something from its pages, and find it of constant value as a reference work R SARGENT

TRANSISTOR ELECTRONICS

Junction Transistor Electronics

By Richard B Hurley Pp xvii+473 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd , 1958) 100*s* net

Transistor Electronics

By Arthur W Lo, Richard O Endres, Jakob Zawels, Fred D Waldhauer and Chung-Chih Cheng Pp xii+521 (London Macmillan and Co , Ltd , 1958) 45*s* net

ON its own Hurley's book has a certain amount to commend it is, however, difficult to understand the publishing policy of Messrs John Wiley and Sons About a year ago they published an excellent work on junction transistors edited by R F Shea, a book which received very favourable reviews Hurley covers much the same ground as Shea, differing only in detail, and although I must admit his book is possibly designed more for use as a text-book, it cannot help being a competitor to Shea's work

Introductory chapters on semi-conductor principles lead on to the small signal equivalent circuit of the transistor and the use of this circuit in the analysis of the transistor audio-amplifier A chapter is devoted to bias stabilization and another to the application of negative feedback The subject-matter of Chapter 6, "The Nature of Internal Noise Generation and Its Outward Effects", receives much better treatment than in Shea's book where it was dismissed, rather perfunctorily, in about a page

The performance of a transistor under large signal conditions is considered and this leads to the problems of the design of power amplifiers Direct-current amplifiers, video amplifiers, tuned amplifiers, automatic gain control, sinusoidal oscillators, modulation circuits all receive attention by way of separate chapters Three more chapters deal with transistors in switching applications and in their use as relaxation oscillators

Two rather special applications of the transistor, namely, in regulated power-supplies and saturable reactor-circuits, have individual chapters and receive a more detailed treatment than in Shea's work

As a book for reference it suffers from the absen of a list of symbols, and what is more serious, althoug the author himself admits it, is the use of the san symbol with entirely different, and different shad of, meaning

The presentation and reproduction is, of cours up to John Wiley's usual high standard

The work on "Transistor Electronics" by I *et al* is a reprint of a well-known book published 1955 in the United States by Prentice-Hall It h now been published in Britain by Macmillan, but t printing was carried out (and very well, too) in t Netherlands So far as I can see there are no alter tions to the original text It covers substantially t same ground as Hurley's book but of course Hurl has three extra years development to include, a in a field that is subject to continual metamorpho this gives him a considerable advantage

The authors, who were all with the Radio Corpor tion of America when the book was written, favo the four-terminal network approach to the transist equivalent circuit and deduce the performance the various circuits using this as the basis A ve useful table shows the many varied forms the fou terminal equivalent network can take and will very useful for reference The book is intended bo as a text-book for students of this subject and as reference work, but I feel that it is in the form application that it will be most useful

J W R GRIFFITHS

PROGRESS IN PHYSIOLOGY

Annual Review of Physiology

Vol 21 Edited by Victor E Hall, in associati with Frederick A Fuhrman and Arthur C Gies Pp viii+636 (Palo Alto, Calif · Annual Review Inc , and the American Physiological Society, 195 On sale by Annual Reviews, Inc) 7 dollars

WITH the publication of Vol 21, the "Annu Review of Physiology" comes of age, though it still a mere fledgling to its 28-year sister publicatio the "Annual Review of Biochemistry". Its grow over the years might be considered unphysiologic for its size at birth (705 pages) was greater than is now (636 pages) The editorial committees ha prevented the volume from becoming unmanageab large, but the question they raised last year remai unanswered whether the present policy of "ski ming one volumeful of physiological cream" can continued indefinitely With the growing output research, it means that a progressively smaller pr portion of the total published work is reviewed ye by year A similar problem exists for annual revie in other subjects Those who write the reviews a faced with the difficulty of selection If they inclu too many papers in their survey, they tend to produ little more than an annotated card index, useful f reference but almost impossible to read through they select some of the more important recent wo in their subject and give themselves room to discu it, they produce a more interesting and stimulati review but may leave out a good deal of significa research On the whole, the present reviewers ha managed to make their summaries interesting read and useful for reference

The prefatory chapter is by A V Hill and de with the heat production in muscle and nerve fro

348 (when Helmholtz made the first attempts at ıeasurement) to the outbreak of the First World 'ar The chapter is preceded by a portrait of its ıthor at work, complete with umbrella installed as a otection against floods from the laboratory above ' rof Hill discusses some of the earlier work in the ght of present-day knowledge and he includes miniscences of research at Cambridge and of some the people there and elsewhere who influenced him is good to know that this chapter will be the eginning of a future monograph

This year's volume contains the usual chapters ı the basic subjects, heart, peripheral circulation, spiration, digestion, kidney, water and electrolyte etabolism, the nervous system (four reviews) and production There are chapters on blood clotting, ne, transport through membranes, heat and cold, ıd chemical influences on cell division and development Endocrinology this time covers the adeno-pophysis and adrenal cortex, and the pancreas ısulin and glucagon)

The chapter on Russian physiology deals with etabolism and endocrinology This is the last time ıat Soviet research will be treated separately In ture, reviewers will be encouraged to make use of ıe translations of Russian papers which are becoming creasingly available, and to discuss these papers ong with the work from other countries The final ıapter, on comparative physiology, reviews work on e annual reproductive cycles of marine inverte-ates

The editorial committee pays its usual tribute to e authors (who write from six different countries) r undertaking the heavy task of preparing these ırveys, all physiologists will wish to associate emselves with this tribute, and will wish the Annual Review of Physiology" many further years useful life

D C HARRISON

RUMINATION

etabolism in the Rumen

y E F Annison and D Lewis (Methuen's Mono-aphs on Biological Subjects) Pp 184 (London ethuen and Co, Ltd, New York John Wiley d Sons, Inc, 1959) 15*s* net

HIS is an interesting, well-written and up-to-date account of the microbiology of digestion in e rumen and the resultant biochemical pathways metabolism In the rumen complex interactions ke place which account for the importance of the minant in agriculture Mammals do not secrete llulases in their digestive juices, and the degradation dietary cellulose in the rumen, its major function, achieved by the cellulolytic activities of the micro-al population This releases potential substrates om refractory plant materials and permits the rmation of metabolic end products in the rumen ıich are afterwards the main source of energy for e animal This enables ruminants to live on coarse rous foods which would otherwise not be available . other herbivora, such as the horse, there is a nilar but more limited dependence on the activities the micro-organisms of the cæcum

The production of certain essential amino-acids and tamins and the conversion of some dietary con-tituents into microbial substance are other metabolic ansformations Symbiotic relationships of a remarkable degree have thus been developed in the rumen The separate metabolic pathways can seldom be adequately examined or controlled in isolation The microbiol activities are delicately poised between catabolic and anabolic processes Thus, for example, in protein metabolism the microbial contributions may range from a rapid breakdown of excess ingested protein to ammonia and volatile fatty acids, to the extreme synthetic phase whereby urea from the circulating blood may diffuse into the rumen and be used for the growth of cellulose fermenting bacteria The techniques now becoming available to the biochemist, physiologist and microbiologist are enhancing their ability to study rumen function, one of the most fascinating and rewarding fields for their attention

It is hoped that this book will help to dispel the considerable ignorance of many biochemists, physiologists and bacteriologists concerning what happens in the ruminant The study of such animals should have its place in the normal curriculum of these subjects While some of the pioneer work was set in motion by Tappeiner in Germany and by Schalk and Amadon in North Dakota, workers in the United Kingdom have made remarkable advances in this fascinating field, and the names of Baker, Barcroft, Phillipson, Elsden, Pearson, Smith, Oxford, McDonald, Synge and Chalmers are to be listed among the pioneers But Marston in Australia, Hungate, Bryant, Doetsch, Gall and Huhtanen in the United States, Balch, Blaxter and Hobson in Great Britain have, among many others, made their mark The authors, too, have justified their position to be knowledgeable authorities in this field

A LIVING organism has a present and two pasts, one evolutionary and the other ontogenetic A study of any one of the three is ultimately comprehensive and will embrace the other two; any knowledge of one must be relevant to the others, and yet to each there is a distinctive biological approach

The developmental biology conference series, a marathon of discussion meetings held in the United States with international participation in 1956, can be said to mark the end of a period during which the developmental approach to biology has been establishing its aims and staking its frontiers Embryology, in the strict sense, is no longer granted automatic precedence, nor is morphogenesis the key problem Events in any part of the ontogenetic cycle are seen in terms of the contribution they can make to an understanding of the whole

These meetings were thus. if anything, even less restricted in scope than might be suggested by the titles of the volumes in which they are reported Though there is remarkably little repetition of one in another, between them they touch upon a substantial fraction of all experimental biology However, it was not intended that the series should be comprehensive and there are, inevitably, many gaps, some premeditated and others contingent upon the informal nature of the discussions This is not a fault, but it does mean that some of the reports will be of most value to those already familiar with the background to the themes discussed This is true, for example, of "Cytodifferentiation" and of "Environmental Influences on Prenatal Development", both of which contain stimulating presentations of recently discovered facts and recently developed ideas On the other hand, the more formal reviews in "Regeneration in Vertebrates" provide excellent and comprehensive surveys of a few selected experimental situations

These seven volumes do indeed vary greatly in character, partly because the meetings themselves took different forms and partly by editorial decision At the one extreme (for example, in "Embryonic Nutrition") we are offered an orthodox sequence of papers and discussions of them, with a complete list of the authorities referred to At the other (in "Immunology and Development") the identities of discussion leaders, participants, and absent authorities are not defined and their work is merged into a sort of collective stream-of-consciousness report Both volumes are successful, but their usefulness is clearly of different kinds

Formal considerations apart, it must be confessed that the series, viewed as a whole, lacks the intellectual coherence that the "unity of subject matter" claimed for it by its organizer, Paul Weiss, might lead one to expect We have not yet a continuous spectrum of problems in developmental biology But these meetings certainly reflected real progress towards a consciously unified approach to developmental processes, a progress that will be further stimulated by the publication of their proceedings.

THE HETEROGENEITY OF HUMAN HÆMOGLOBIN

Abnormal Hæmoglobins

A Symposium Organized by the Council for International Organizations of Medical Sciences Edited by J. H P Jonxis and J F Delafresnaye Pp ix+427. (Oxford· Blackwell Scientific Publications, Springfield, Ill Charles C Thomas, 1959) 45s net

THIS volume contains the papers and discussions of a symposium on abnormal hæmoglobins held in Istanbul in September 1957. Since Pauling's demonstration in 1949 of an electrophoretically distinct hæmoglobin in sickle-cell anæmia, the discovery of new variants has proceeded with increasin momentum so that, at present, 15 hæmoglobins hav been designated by letters of the alphabet Four sub fractions of normal adult human hæmoglobins, A_1 A_2, A_3, A_4 (A_2'), and one normal fœtal hæmoglobi are now known The complexity of the situatio is illustrated by reports of a further seven variant which are given provisional names derived from th place of discovery, in order to avoid confusion of th nomenclature

The interest in abnormal hæmoglobins is spreadin throughout the world, and involves many scientifi disciplines It is this widespread multidisciplinar interest which has brought the subject within th ambit of the Council for International Organization of Medical Sciences Participants in the symposiu included eminent workers of international repute, an others who have become recognized for their work i their own geographical localities The papers hav been grouped under two main headings "Biologica Considerations" and the "Geography of Hæmoglobins" Itano (United States) opens the symposiu with an introductory discourse on the "Genetic an Physical Factors in the Heterogeneity of Hæmoglobin" The identification of human hæmoglobin is described by Huisman (Holland), though practica details of technique are not given This paper i supplemented by Cabannes and Portier (Algiers with a description of their electrophoretic experience of the newly discovered hæmoglobins Two group of workers using two different techniques bring fort evidence that the alkali-resistant hæmoglobin o thalassæmia is not fœtal hæmoglobin a view no held by the majority of authorities Derrien (France bases his evidence on solubility experiments, whi Dianoco and Castay (Tunis) describe immunologica differences using a complement fixation test for th detection of hæmoglobin antibodies Clinical an hæmatological aspects of the various hæmoglob syndromes are described by Zuelzer (United States Chapters on fœtal and sickle cell hæmoglobin ar provided by Jonxis (Holland) and Vandepitte (Belgia Congo) respectively Fessas (Greece) described th alterations of the hæmoglobin pattern in thalassæmi The first section is concluded by chapters on th genetic aspects by Neel (United States) and o the hæmoglobin types of animals by Huisma (Holland) and his colleagues

In the part on geography, the following autho have dealt with the position of abnormal hæmoglobins in their region Aksoy (Turkey), Pouy (Iran), Silvestroni and Bianco (Italy), Fessas (Greece Vandepitte (Belgian Congo), Portier, Cabannes an Duzer (Algiers), Edington (Ghana), Chatterjea (India de Silva, Jonxis and Wickramasinghe (Ceylon), Na Nakorn (Thailand), and Lie-Injo Luan Eng (Indonesia Prof Jonxis contributes some interesting compariso of the frequencies of the sickle-cell and hæmoglob C traits in the Dutch colonies of Curacao and Surina Two chapters by Lehmann (United Kingdom) pu the subject of hæmoglobin variants in their prope geographical perspective

The nomenclature of the newer hæmoglob variants H–N is given in an appendix, togethe with the studies required before a new hæmoglob can be designated

This volume will provide a useful account of th abnormal hæmoglobin situation up to early 195 whether the reader be a hæmatologist, physicia biochemist, geneticist or anthropologist

J A M Ager

A Handbook of Lattice Spacings and Structures of Metals and Alloys

By Dr. W. B. Pearson. (International Series of Monographs on Metal Physics and Physical Metallurgy, Vol. 4.) Pp. x+1044. (London and New York: Pergamon Press, 1958.) 262*s*. 6*d*.

THIS is a formidable work of more than 1,000 pages. It is divided into two parts. The first part is an account of the methods used in the accurate determination of lattice spacings and crystal structures, and of the significance of the results in connexion with the location of phase boundaries, the application of electron theory to metals and alloys, and the effect of magnetic properties on lattice spacings. A brief mention is also made of the role of lattice parameter measurements in miscellaneous fields such as thermal expansion and superconductivity.

The second part occupies most of the book, and consists of a collection of crystallographic data. This includes the lattice spacings and crystal structures of the elements, of binary, ternary and quaternary alloys, and of borides, hydrides, carbides, nitrides and oxides. The largest section in this part is an alphabetical index of the work on metals and alloys. For each alloy system a brief description of the equilibrium diagram is given, together with a critical assessment of the various lattice parameters obtained by different workers. Sufficient practical information on the methods of obtaining the data is given to make it unnecessary in most cases to refer to the original papers. References are included up to 1957.

The labour involved in producing this work must have been considerable, and the author is to be congratulated on the result. It will prove to be of great value to the research worker, and should be in the library of all people who are interested in the physics of metals. The book is unfortunately very expensive.

J. A. CATTERALL

The Birds of Sydney (County of Cumberland), New South Wales

By K. A. Hindwood and A. R. McGill. Pp. iii+128+19 plates. (Sydney: Royal Zoological Society of New South Wales, 1958.) 12*s*. 6*d*.

THE Sydney Basin is essentially Triassic in origin and was formed by successive lake deposits overlying coal measures of Permian age. Above the coal is red shale, and above this there lies a tough sandstone surmounted by a final capping of grey shale. Here and there erosion has bared the underlying structures; in fact, the city of Sydney is built on and partly of Hawkesbury sandstone. Each geological type supports its own characteristic flora and, correspondingly, fauna. The red shale of the deep valleys has attracted an Indo-Malayan vegetation, as well as a fauna partly of northern affinity. The flowering heaths of the sandstone support many honey-eating animals and others; and in the open forests of the surviving top-shale is found a fauna which is often closer allied to that of the dry interior than to the animals in the cool valleys nearby.

Messrs. Hindwood and McGill have compiled a useful list of the 377 species of birds—both land and marine—native to this zoologically fascinating region. Under each name are five or six lines, mentioning salient points of description and the localities in which each species can be found. The compilation, therefore, remains of strictly local interest; and this is a pity. The area abounds with problems relating to the wider aspects of avian zoogeography, ecology and dispersal and it is regrettable that no attempt has been made to get to grips with such matters. The book is illustrated with a map of the area and excellent photographs of about thirty species.

A. J. MARSHALL

Food for Survival after a Disaster

By Dr. R. C. Hutchinson. Pp. ix+90+6 plates. (Carlton, N.3: Melbourne University Press; London: Cambridge University Press, 1959.) 13*s*. 6*d*.

THE disaster envisaged in the title is that of shipwreck, forced plane landing, or vehicle breakdown in a desert area, rather than the large-scale disaster of modern war, and the information given is primarily that which would be of the greatest value to individuals or small groups of survivors trying to keep alive under adverse conditions in strange surroundings. In addition to this, however, the book also contains much pertinent detail on de-salting kits and on the selection and packaging of survival rations which would be of great use to those planning scientific expeditions and to commercial shipping and air-line companies who may not have access to pamphlets prepared for the Armed Forces.

The author claims to speak from personal experience as "a survivor on both land and sea", and has certainly condensed a wealth of material into a very small space and presented it in a most readable form. The chapter on "Possible Supplementary Sources of Food" is a whole lesson in ecology in itself and one that should stimulate the interest of any school-boy. Decidedly a book to be recommended to all inveterate travellers: the day might well come when they would owe their lives to what they had learnt from its pages.

M. W. GRANT

From Microphone to Ear

Modern Sound-Recording and Reproduction Technique. By G. Slot. Second, revised and enlarged edition. Pp. ix+258. (Eindhoven: Philips' Technical Library; London: Cleaver-Hume Press, Ltd., 1959.) 21*s*.

THIS book might well be entitled "Gramophones, from *A* to *Z*", for it seems to contain everything, even (p. 82) how to remove gin spots from your records! It is obviously written by an enthusiast for enthusiasts, and its quality has been well preserved in the excellent translation. Many an amateur constructor, 'hi-fi' or stereophony fan, or even the intelligent listener with a curiosity to learn more of what gets the music on to the records and out of the loudspeaker, will find plenty of reading here. Recording techniques, studio work, tracking theory, loudspeaker dynamics, cabinet design, motor construction, care of records, negative feedback, tape recorders, sound effects, automatic record changers, needles, hum—the lot.

With this enormous coverage the treatment of much of the material will seem shallow to professionals and it would be easy to be critical, but purposeless. The book is informative, practical, well written and illustrated by many simple line diagrams and photographs. It makes a welcome and timely appearance, in these days of such increased demand for better musical recording and reproduction. Many enthusiasts want to assess the merits of this technique and that, or to judge the quality of their equipment, or to improve it; this book will help them.

COLIN CHERRY

ELECTRONIC PREDICTION OF SWARMING IN BEES

By E F WOODS*

THE honey bee is one of man's two domesticated insects (the other being the silkworm), and has been cultivated before the dawn of history, principally for the production of honey The primitive method of beekeeping revolved around the instinct of bees to swarm Each colony produced by swarming 6–15 new colonies, usually in spring, and those colonies were hived and allowed to build up in the summer, gathering and storing honey In the autumn, all but one of the colonies resulting from one mother colony were destroyed, and the honey and wax harvested The remaining colony repeated the cycle next year This system is still in use in some countries, such as Abyssinia, Palestine, and India, but is rapidly falling into disuse.

In 1851, Langstroth, in the United States of America, introduced the movable-frame hive and found that, if swarming could be prevented, the quantity and quality of the honey were enormously improved But the difficulty lay in preventing swarming, the bees' natural method of reproduction, and for a century the only method known has been meticulously to examine all colonies at regular intervals, and take appropriate action with those showing visible signs of an impending swarm, namely, queen cells This examination is made on each colony every 9 or 10 days from about mid-April to mid-July—about eight operations in a season—and takes 5–10 min for a skilled operator, who must be physically robust, since he has to lift the components of a hive weighing up to 60 lb each The repeated disturbance to the bees seriously reduces the honey crop Moreover, since only about 3 per cent of the colonies show signs of swarming, 97 per cent of this work is wasted When it is realized that this system is applied to more than 10,000,000 colonies of bees throughout the world—more than 5,000,000 in the United States alone—the tremendous waste of labour and honey becomes obvious This system is costly in labour (about £3 per colony per annum), and the loss of honey due to disturbance is also considerable, quite comparable in value with the actual outlay in labour

My work on the analysis of the sounds of activity in the hive indicated that small variants of the normal sound could be identified which were indicative of abnormality Certain characteristic sounds in particular were found to be adequate criteria for, among other possibilities, the prediction of swarming A technique was therefore developed, and an instrument designed and produced for monitoring the condition and behaviour of a colony with no disturbance to the bees whatsoever

An analysis of the sound spectrum of a large healthy colony of bees, in three conditions, is given in Fig 1, curves I, II and III. These curves were obtained by two methods by selecting the wanted sound by means of a filter circuit and relating it by ear to a similar pure tone, attenuated , and by the use of a standard wave-analyser The two methods gave similar results, and the second was adopted, being much simpler and quicker As no absolute standard is available, all sounds were related to the loudest, the flight noise

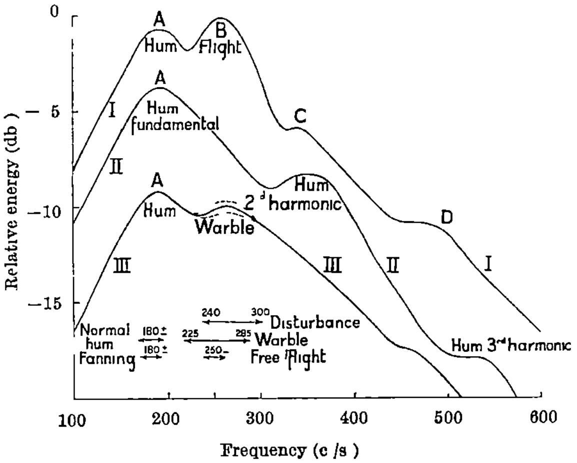

Fig 1 *Apis mellifica*, same colony July 7–8, 1959
I, 2 p m , harvesting , II, 2 a m , no flight , III, deprived of fliers and dequeened

Fig 1, curve I, represents the normal day-time spectrum *A* is the basic sound produced by the action of the spiracular valves on the inspired and expired air, varying for an individual bee in synchronism with the breathing movements, but amounting *en masse* to a steady hum at 180 ± 5 c /s *B* shows the flight sound, with a frequency of 250 ± 1 c /s *C* and *D* are harmonics of *A* and *B*, merging at high frequencies There is no supersonic component

Fig 1, curve II, refers to the same colony after dark The general sound is weaker, and the flight component is missing Curve III is from the same colony, deprived of fliers, and with the queen removed, the recording having been taken 3 hr after her removal The important component at 225–285 c /s will be noted, varying somewhat in frequency, but not more than ± 3 db in volume, which has built up steadily to a maximum It is almost a true warble technically so defined

This warble is a consequence of the removal of the queen, and the time at which it appears varies with several factors (*a*) the smaller the colony the shorter the time and vice versa , (*b*) the busier the colony, the longer it takes to appear , (*c*) the presence of numerous nurses at certain times of the year shortens the period , (*d*) the period varies with different breeds of bee, the more 'phlegmatic' dark bees tending to have slower reactions

The warble not only increases in volume, building up relatively steadily to a peak, but its nature also changes For a typical time of 5 hr from removal of the queen to maximum sound, the process would be as follows.

0–10 *min* A faint, steady rise and fall in the frequency-range 225–285 c /s , made by the nurse bees immediately attendant on the queen, probably those obtaining queen substance from her

---

* Present address 91 Manor Road South, Esher, Surrey

10 min–3 hr. A bubbly, jerky sound, in the same frequency-range, somewhat plaintive The bees act as if distressed, and are very subdued in behaviour

3–5 hr The warble, still in the range quoted becomes more jerky and fierce The bees become irritable

5 hr The sound becomes a twanging sound, and at this point the bees tend to become intractable and fierce Queen cells appear

After 5 hr The warble disappears in a few minutes and is replaced by the 'roar', a sound of frequency 180 ± 2 c /s , varying in volume by ± 20 db The bees are now usually intractable and vicious

At any time during the warbling, the queen can be replaced with little risk of loss, and at the peak, her acceptance by the colony is almost certain After the cessation of the warble, introduction of a queen is almost impossible

A large number of experiments over several years showed that the warble was produced by nurse bees. aged 4½–6 days, and that it could be related very accurately to their inability to dispose of the royal jelly, automatically produced at this age This general explanation covered every observation of the occurrence of the warble at any season and in all conditions

Partial slowing down of oviposition occurs during the 'fining down' of the queen in the pre-swarm period, giving rise to a progressively increasing warble as more and more nurse bees are thrown out of work, but it has not hitherto been noticed, because not only is it very weak, but also the fliers which comprise the swarm, no longer stimulated to fly for harvest, remain in the colony and increase the normal sound.

It therefore appeared that an increasing warble should be detectable from the start of swarm-preparation, and that a means of detecting it might afford a means of predicting the onset of swarming

It will, however, be obvious from the curves that this sound, at its very loudest, and with fliers removed, is 10 db below the general noise-level, and is never clearly audible to the unaided ear until the swarm has left the hive

A filter amplifier circuit was therefore constructed, reducing all frequencies outside the range 255 ± 30 c /s , and providing considerable amplification to the residue, and it was found that the warble was distinguishable as much as 25 days before the issue of the swarm, and clear and unmistakable about 15 days before swarming Thus with a suitable nstrument, the onset of swarming can be predicted a week or more before the visible signs—namely, queen cells—are laid down, and a fortnight before the issue of the swarm

A complication arises in that many, probably most, colonies supersede a failing queen at least once, the daughter mating and ovipositing before the mother is destroyed (by the bees) There is thus only a small decrease in egg production, but the progressive failure of the old queen, reducing the supply of queen substance, has an effect similar to egg reduction, and the nurses warble, a sound weaker but in no way different from the pre-swarm warble It is, however, quite easy to determine which process is in prospect If a colony be disturbed, it produces a characteristic hiss, and if the colony is in breeding-balance, that is to say, the eggs and young larva are fairly well equated to the nursing potential, this is a short vicious sound, lasting only tenths of a second before ceasing To get this 'shape' of sound, the stimulus must be short and apply to all bees a jerk on the hive suffices If the number of eggs is falling relatively to the nursing potential, the sound has the same character, but is reduced in peak volume and lengthened in time With a little practice it is easy to distinguish an incipient swarm from supersedure

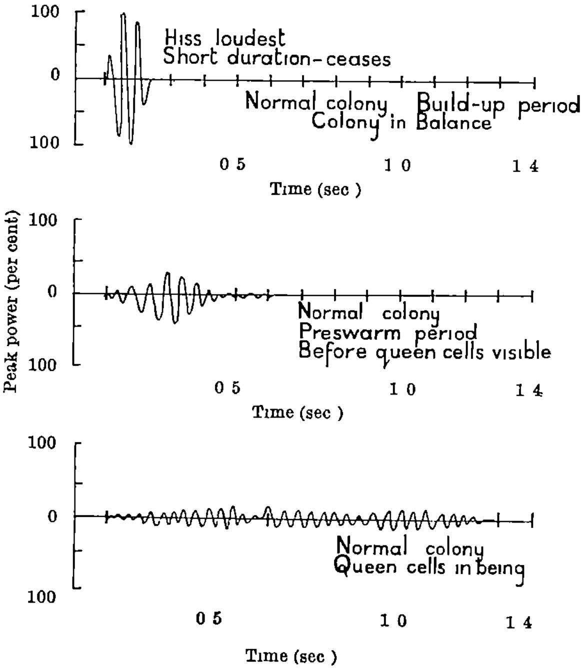

Fig 2 Hiss (diagrammatic) In the queen cell-in-being diagram (bottom) the duration grows to 10 sec or more and the power vanishes to zero

To permit the reliable assessment of the hiss—a random spectrum of sound from about 3,000 c /s upwards—a second filter was constructed The hiss was then amplified and presented to the ear in unmistakable volume Fig 2 illustrates the hiss cycle It should be noted that Fig 1 represents actual measurements on a typical colony, whereas Fig 2 is diagrammatic

Fig 3 shows the progress of a pre-swarm cycle The build up of warble can be regarded as typical, but it should be understood that it varies both in frequency, that is, it warbles, and also from instant to instant in volume The frequency excursion is now quite definite, from 225 to 285 c /s , but the instantaneous variation in volume seems to be unpredictable However, the average volume rises steadily as shown (Fig 3)

The practical utilization of these sounds requires an instrument which not only selects and amplifies them, but is also simple to operate, robust, cheap and weatherproof It must also be battery driven The recent development of transistors and 'Ferroxcube' inductors has enabled these stringent requirements to be fulfilled in an instrument patented under the name 'Apidictor'[1], of which a number have been constructed and are in regular use

Early models were portable, with a microphone on a probe, to be inserted in the entrance to the hive at the bottom of the brood-box This caused some disturbance, the stinging reaction, and also the instrument was necessarily close to the flight sound. Both these sounds are in the warble frequency-range, and considerable skill was needed to distinguish the

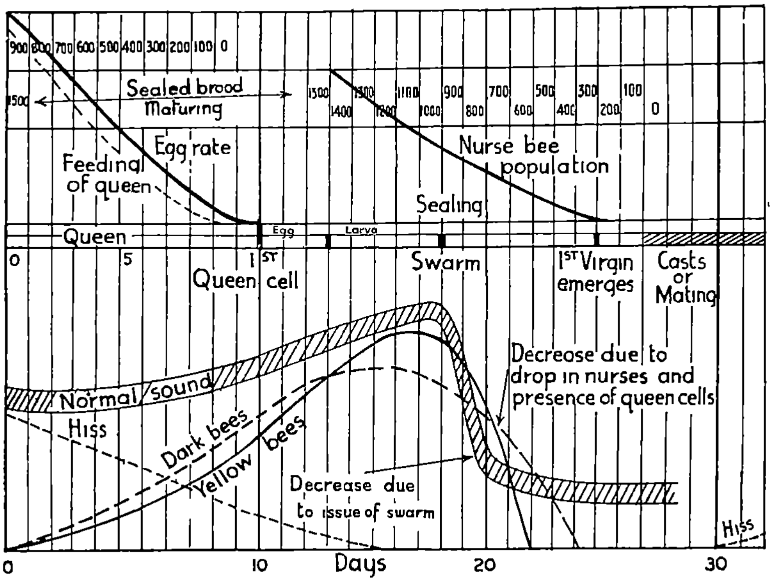

Fig 3 Swarm cycle

warble Furthermore, the warble 'radiates' from the queen, which is usually at the top of the brood-box, away from the entrance

Disturbance was eliminated, and the relative volume of the warble increased by placing a microphone permanently inside the hive at the top, but the adverse conditions of heat and humidity destroyed the (crystal) microphone fairly quickly, and the running cost of one microphone per hive per season was excessive

A scheme which has proved successful and economical utilizes a hole in the back of the brood-box at the top, with an internal screen of perforated zinc, and plugged with a rubber bung This bung is removed and the microphone, mounted in an identical bung, plugged in This third plan also removes a disadvantage of the second, namely, the variability of microphones, especially after some weeks in the hive

Headphones, of the familiar stethophone pattern, are used as a detector, but later development may permit the use of a visual indicator, at an increased cost An automatic alarm system is also possible for use in large centralized apiaries

The 'Apidictor' was primarily visualized as a swarm predictor, for which it has obvious economic advantages, but it has a great range of other uses It removes almost completely the uncertainty of queen introduction and queen cell acceptance, it detects abnormalities such as queen failure, that is, drone breeding, and it enables an accurate check to be made of the health of the colony in winter, even during heavy frost[1]

I wish to acknowledge the enthusiastic and skilled co-operation of many friends, but particularly of Mr E F Birch of Hereford, who has been working with me since 1951, and of Mr C B Dennis of Harrow, who has co-operated with me for the past three years I also wish to thank Messrs Wayne Kerr Laboratories of Surrey, for invaluable technical assistance

[1] British Patent No 729,067 (1958)

SEARCHING FOR INTERSTELLAR COMMUNICATIONS

By GIUSEPPE COCCONI* and PHILIP MORRISON†

Cornell University, Ithaca, New York

No theories yet exist which enable a reliable estimate of the probabilities of (1) planet formation , (2) origin of life , (3) evolution of societies possessing advanced scientific capabilities In the absence of such theories, our environment suggests that stars of the main sequence with a lifetime of many billions of years can possess planets, that of a small set of such planets two (Earth and very probably Mars) support life, that life on one such planet includes a society recently capable of considerable scientific investigation The lifetime of such societies is not known , but it seems unwarranted to deny that among such societies some might maintain themselves for times very long compared to the time of human history, perhaps for times comparable with geological time It follows, then, that near some star rather like the Sun there are civilizations with scientific interests and with technical possibilities much greater than those now available to us

To the beings of such a society, our Sun must appear as a likely site for the evolution of a new society It is highly probable that for a long time they will have been expecting the development of science near the Sun We shall assume that long ago they established a channel of communication that would one day become known to us, and that they look forward patiently to the answering signals from the Sun which would make known to them that a new society has entered the community of intelligence What sort of a channel would it be ?

The Optimum Channel

Interstellar communication across the galactic plasma without dispersion in direction and flight-time is practical, so far as we know, only with electromagnetic waves

Since the object of those who operate the source is to find a newly evolved society, we may presume that the channel used will be one that places a minimum burden of frequency and angular discrimination on the detector Moreover, the channel must not be highly attenuated in space or in the Earth's atmosphere Radio frequencies below ~ 1 Mc /s , and all frequencies higher than molecular absorption lines near 30,000 Mc /s , up to cosmic-ray gamma energies, are suspect of absorption in planetary atmospheres The band-widths which seem physically possible in the near-visible or gamma-ray domains demand either very great power at the source or very complicated techniques The wide radio-band from, say, 1 Mc to 10^4 Mc /s , remains as the rational choice

---

* Now on leave at CERN, Geneva

† Now on leave at the Imperial College of Science and Technology, London, S W 7

In the radio region, the source must compete with two backgrounds (1) the emission of its own local star (we assume that the detector's angular resolution is unable to separate source from star since the source is likely to lie within a second of arc of its nearby star) , (2) the galactic emission along the line of sight

Let us examine the frequency dependence of these backgrounds A star similar to the quiet Sun would emit a power which produces at a distance R (in metres) a flux of

$$10^{-15} f^2/R^2 \quad \mathrm{W\ m^{-2} (c\ /s\ )^{-1}}$$

If this flux is detected by a mirror of diameter l_d, the received power is the above flux multiplied by $l_d{}^2$

The more or less isotropic part of the galactic background yields a received power equal to

$$\left(\frac{10^{-12.5}}{f}\right) \left(\frac{\lambda}{l_d}\right)^2 (l_d)^2 \quad \mathrm{W\ (c\ /s\ )^{-1}}$$

where the first factor arises from the spectrum of the galactic continuum, the second from the angular resolution, and the third from the area of the detector Thus a minimum in spurious background is defined by equating these two terms The minimum lies at

$$f_{\min} \approx 10^4 \left(\frac{R}{l_d}\right)^{0.4} \mathrm{c\ /s}$$

With $R = 10$ light years $= 10^{17}$ m and $l_d = 10^2$ m $f_{\min} \approx 10^{10}$ c /s

The source is likely to emit in the region of this broad minimum

At what frequency shall we look ? A long spectrum search for a weak signal of unknown frequency is difficult But, just in the most favoured radio region there lies a unique, objective standard of frequency, which must be known to every observer in the universe the outstanding radio emission line at 1,420 Mc /s (λ = 21 cm) of neutral hydrogen It is reasonable to expect that sensitive receivers for this frequency will be made at an early stage of the development of radio-astronomy That would be the expectation of the operators of the assumed source, and the present state of terrestrial instruments indeed justifies the expectation Therefore we think it most promising to search in the neighbourhood of 1,420 Mc /s

Power Demands of the Source

The galactic background around the 21-cm line amounts to

$$\frac{\mathrm{d}W_b}{\mathrm{d}S\ \mathrm{d}\Omega\ \mathrm{d}f} \approx 10^{-21.5} \quad \mathrm{W\ m^{-2}\ ster^{-1}\ (c\ /s\ )^{-1}}$$

for about two-thirds of the directions in the sky In the directions near the plane of the galaxy there is a background up to forty times higher It is thus economical to examine first those nearby stars which are in directions far from the galactic plane

If at the source a mirror is used l_s metres in diameter, then the power required for it to generate in our detector a signal as large as the galactic background is

$$\frac{\mathrm{d}W_s}{\mathrm{d}f} = \frac{\mathrm{d}W_b}{\mathrm{d}S\ \mathrm{d}\Omega\ \mathrm{d}f} \left(\frac{\lambda}{l_s}\right)^2 \left(\frac{\lambda}{l_d}\right) R^2 = 10^{-24.2} R^2/l_s{}^2 l_d{}^2 \quad \mathrm{W\ (c\ /s\ )^{-1}}$$

For source and receiver with mirrors like those at Jodrell Bank ($l = 80$ m), and for a distance $R \simeq 10$ light years, the power at the source required is $10^{2.2}$ W (c /s)$^{-1}$, which would tax our present technical possibilities However, if the size of the two mirrors is that of the telescope already planned by the U S Naval Research Laboratory ($l = 200$ m), the power needed is a factor of 40 lower, which would fall within even our limited capabilities

We have assumed that the source is beaming towards all the sun-like stars in its galactic neighbourhood The support of, say, 100 different beams of the kind we have described does not seem an impossible burden on a society more advanced than our own (Upon detecting one signal, even we would quickly establish many search beams) We can then hope to see a beam toward us from any suitable star within some tens of light years

Signal Location and Band-Width

In all directions outside the plane of the galaxy the 21-cm emission line does not emerge from the general background For stars in directions far from the galactic plane search should then be made around that wave-length However, the unknown Doppler shifts which arise from the motion of unseen planets suggest that the observed emission might be shifted up or down from the natural co-moving atomic frequency by $\pm \sim 300$ kc /s (± 100 km s^{-1}) Closer to the galactic plane, where the 21-cm line is strong, the source frequency would presumably move off to the wing of the natural line background as observed from the direction of the Sun

So far as the duration of the scanning is concerned, the receiver band-width appears to be unimportant The usual radiometer relation for fluctuations in the background applies here, that is

$$\frac{\Delta B}{B} \propto \sqrt{\frac{1}{\Delta f_d\, \tau}}$$

where Δf_d is the band-width of the detector and τ the time constant of the post-detection recording equipment On the other hand, the background accepted by the receiver is

$$B = \frac{\mathrm{d}W_b}{\mathrm{d}f} \Delta f_d \text{ and } \tau \propto \frac{\Delta f_d}{(\Delta B)^2}$$

If we set ΔB equal to some fixed value, then the search time T required to examine the band F within which we postulated the signal to lie is given by

$$T = \frac{F\tau}{\Delta f_d} \propto \frac{F}{(\Delta B)^2}$$

independent of receiver band-width Δf_d

Of course, the smaller the band-width chosen, the weaker the signal which can be detected, provided $\Delta f_d \gg \Delta f_s$ It looks reasonable for a first effort to choose a band-width Δf_d normal in 21 cm practice, but an integration time τ longer than usual A few settings should cover the frequency range F using an integration time of minutes or hours

Nature of the Signal and Possible Sources

No guesswork here is as good as finding the signal We expect that the signal will be pulse-modulated with a speed not very fast or very slow compared to a second, on grounds of band-width and of rotations A message is likely to continue for a time measured in years, since no answer can return in any event for some ten years It will then repeat, from the beginning. Possibly it will contain different types of signals alternating throughout the years For indisputable identification as an artificial signal, one signal might contain, for example, a sequence of small prime numbers of pulses, or simple arithmetical sums

The first effort should be devoted to examining the closest likely stars Among the stars within 15 light years, seven have luminosity and lifetime similar to those of our Sun Four of these lie in the directions of low background They are τ Ceti, 0_2 Eridani, ε Eridani, and ε Indi All these happen to have southern declinations Three others, α Centauri, 70 Ophiucus and 61 Cygni, lie near the galactic plane and therefore stand against higher backgrounds There are about a hundred stars of the appropriate luminosity among the stars of known spectral type within some fifty light years All main-sequence dwarfs between perhaps $G0$ and $K2$ with visual magnitudes less than about +6 are candidates

The reader may seek to consign these speculations wholly to the domain of science-fiction We submit, rather, that the foregoing line of argument demonstrates that the presence of interstellar signals is entirely consistent with all we now know, and that if signals are present the means of detecting them is now at hand Few will deny the profound importance, practical and philosophical, which the detection of interstellar communications would have We therefore feel that a discriminating search for signals deserves a considerable effort The probability of success is difficult to estimate , but if we never search, the chance of success is zero

METABOLIC CHANGES INDUCED IN MAMMALIAN ERYTHROCYTES BY WHOLE-BODY X-IRRADIATION

By Prof D. A RAPPOPORT and B. W. SEWELL

Department of Biochemistry, Baylor University College of Medicine, Houston, Texas

APPLICATION of X-rays and radium in medicine, after their discovery during 1895–96, established their effectiveness in diagnosis and treatment of disease Only somewhat later were the lethal and injurious properties of these penetrating rays recognized[1] Since then, large groups of men have become exposed more frequently to man-made radiation These additional exposures to penetrating radiation have magnified the need for a reliable indicator of radiation-induced tissue damage What is precisely needed is a simple and accurate indicator which would correlate biological damage with the radiation dose[1]

The requirements of an ideal biological radiation indicator are that (*a*) a tissue or tissue component should show changes over extended periods following whole-body irradiation , (*b*) this change can be quantitatively measured It is also important that tissue samples should be available for intermittent sampling without injury to the subject and without alteration in the system under examination

Choice of Erythrocytes

Certain generalizations can be used in considering this problem in order to initiate a working hypothesis Tentatively it can be assumed that any radiation absorbed by cells will cause changes in the cell enzymes[2], but that the detection of these changes is dependent on (*a*) the sensitivity to radiation of a particular enzyme system under evaluation and (*b*) the degree of sensitivity of the analytical methods employed

Implicit in the above specifications is the fact that the tissue must be incapable of extensive internal repair if it is to reflect any post-irradiation changes This immediately eliminates tissues with large populations of mitotic cells and suggests erythrocytes as the tissue component of choice In man the erythrocyte has a life-span of 110–120 days[3], in the rat this span is 49–55 days[4], in other mammals erythrocyte life-spans are between these values[5] Since mammalian erythrocytes are enucleated, no resyntheses of proteins can occur, and any radiation damage incurred on the enzyme-proteins, such as denaturation or rupture of peptide linkage, should be detectable by changes in enzymic reactions This rationale suggests the erythrocyte enzymes for examination as a test system

If the hypothesis is held that any absorbed radiation will affect enzymes in all cells, how is it that no enzymic changes have been observed in erythrocytes after moderate whole-body irradiation ? This may be explained on the basis that up to the present time few erythrocyte enzymes have been tested after radiation treatment Erythrocyte enzymology has now been more thoroughly explored[6,7] With the complete elucidation of glycolysis, the hexosemonophosphate shunt, the transketolase and transaldolase enzymes, and nucleoside phosphorylase in erythrocyte extracts, re-examination of the radiation effect on these enzyme systems is in order

Nucleoside Metabolism

Investigators concerned with the preservation of blood have found that when inosine or adenosine is added to blood the integrity of the erythrocytes is maintained during storage and their survival following transfusion is improved[8] This was attributed to the resynthesis of metabolites essential for erythrocyte integrity

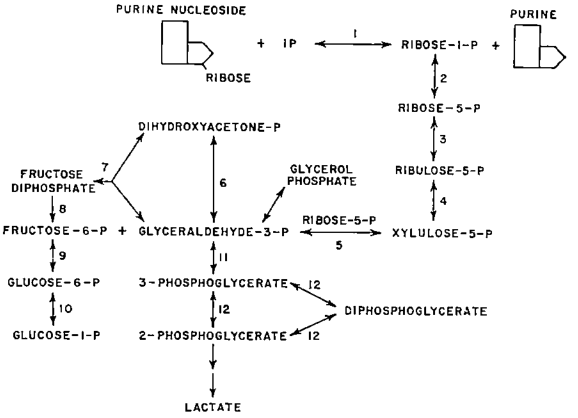

Fig 1 Diagrammatic representation of the metabolic reactions of purine nucleosides in erythrocytes The enzymes involved are (1) nucleoside phosphorylase, (2) phosphoribomutase, (3) phosphoriboisomerase, (4) phosphoketopentoepimerase, (5) transketolase, (6) triosephosphate isomerase, (7) aldolase, (8) fructose diphosphatase, (9) phosphoglucoisomerase, (10) phosphoglucomutase, (11) triosephosphate dehydrogenase, (12) phosphoglyceric mutase

The enzymes responsible for nucleoside metabolism within the erythrocyte are in the soluble portion of the cell The reactions which they catalyse are diagrammatically illustrated in Fig 1 First, the nucleoside in presence of phosphate is converted to ribose-1-phosphate and a purine base by a nucleoside phosphorylase[9] Later, the pentose phosphate is transformed to a variety of phosphate esters via the actions of transketolase, transaldolase and the glycolytic enzymes[6]

When considering nucleoside metabolism in erythrocytes as a system for evaluation of X-ray effects, it can be assumed that if any enzyme among the group of interdependent reactions is inhibited there will be an accumulation of substrate and a change in the yield of phosphate esters Complex multiple enzyme systems, such as are involved in erythrocyte metabolism of nucleosides, have certain disadvantages as well as advantages in studies of radiation effects The disadvantage in such systems is that it may be difficult to determine which particular enzyme was affected by the radiation However, the advantage n using a multiple enzyme system is that this ncreases the opportunity of finding one or more enzymes sensitive to absorbed radiation

Erythrocyte Turnover

In the studies on the enzymic changes at prolonged post-rradiation intervals, time of residence of the circulating erythrocyte is a major factor for consideration This requires that the maximum post-rradiation time-interval used for evaluation must be within the period when the irradiated erythrocyte population is not markedly altered This can be calculated from the erythrocyte life-span

Inbred strains of rats are convenient for radiological studies The 'mean life-span' of rat erythrocytes as well as the 'half-clearance time' can be used to estimate changes in erythrocyte population The mean life-span' of an erythrocyte is the average nterval of time any erythrocytes will remain in circulation, 'half-clearance time' is that time-nterval at which 50 per cent of the circulating erythrocytes will disappear from circulation Belcher and Harriss[4] have recently reported the 'mean life-span' of the rat erythrocyte as 49–55 days The 'half-clearance time' was determined as 20 7 ± 2 5 days

Since these observations are based on the mean life-span and half-clearance time of erythrocytes in the normal rats, it is important to know how these figures are altered in X-irradiated rats Total-body X-irradiation of rats in excess of 300 r causes complete inactivation of marrow and stops the extrusion of erythrocytes into circulation[10] However, the life-span and half-clearance time of the circulating erythrocytes remain relatively the same as in the unirradiated animals[11] There is evidence that random (non-senescent) destruction of erythrocytes, which in the normal rat is approximately 0 48 per cent per day[5,6], is increased in the irradiated animals but the magnitude of this change is unknown[11]

Recognizing the prolonged inactivation of marrow after an X-ray dose of 300 r or higher, we see that the erythrocyte population will consist only of irradiated cells up to and even beyond a two-week period, since no new cells are extruded by marrow during this time However, due to internal hæmorrhages and other undefined factors, random non-senescent loss of erythrocytes will be increased[11] This will cause a drop in the number of red cells, however, loss of plasma into tissue and dehydration due to vomiting and diarrhœa will tend to decrease plasma volume, hence there may be no net change in hæmatocrit values[11].

The above discussion can be summarized by the conclusion that following total-body radiation with doses at and above 300 r the erythrocyte population remains relatively undiluted and the life-span and half-clearance time remain approximately the same as in the unirradiated rat, with the exception that there is an increased random loss of erythrocytes which cannot be quantitatively evaluated at present

It is tentatively concluded that the erythrocyte is a promising tissue component as an internal mammalian X-ray indicator, since (*a*) it has a wide variety of enzymes among which some may be sensitive to radiation, (*b*) it cannot replace altered enzyme-proteins, (*c*) it has a long life-span even in irradiated animals, (*d*) it is accessible for repeated sampling

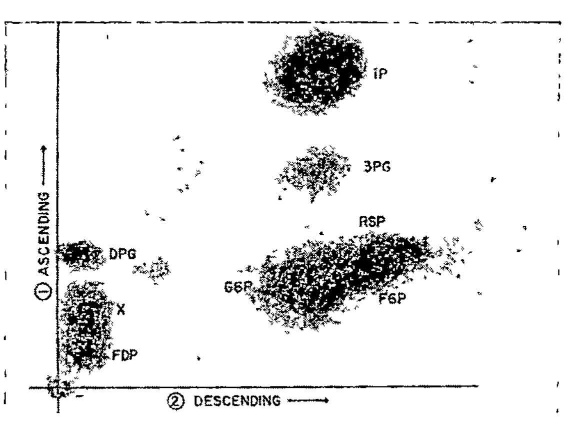

Fig 2 Radioautogram of phosphate esters separated by two-dimensional paper chromatography, (1) ascending with ethyl-acetate, acetic acid and water (3 3 1) and (2) descending with methyl ethyl ketone, methyl cellosolve, ammonia and water (7 2 0 7 2 3) *iP*, inorganic phosphate, *3PG*, 3-phosphoglycerate, *R5P*, ribose-5-phosphate, *G6P*, glucose-6-phosphate, *DPG*, 2,3-diphosphoglycerate, *X*, unidentified ester, *FDP*, fructose diphosphate

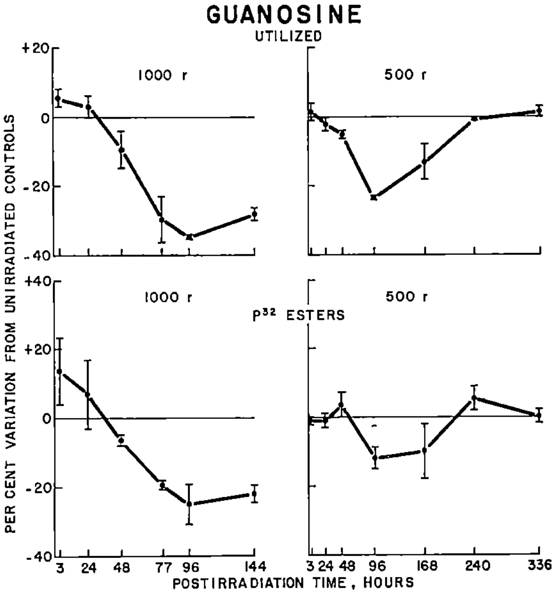

Fig 3 Comparative utilization of guanosine and formation of phosphate esters by rat erythrocyte extracts from rats irradiated with 1,000 and 500 r X-rays, respectively

The concepts discussed above were tested by measuring the changes in nucleoside metabolism by erythrocyte extracts from irradiated and unirradiated rats Our results established that following 1,000 r whole-body X-irradiation the utilization of purine nucleosides was markedly depressed up to 144 hr after irradiation Whole-body irradiation of 500 r also depressed purine nucleoside metabolism for a period of 96 hr, when the metabolism began to increase and by 240 hr reached the level of substrate utilization by erythrocyte extracts from unirradiated controls These results establish that erythrocyte enzymes are affected by moderate whole-body radiation and that these changes are detectable over a period from one to two weeks after irradiation

Experimental Results

Erythrocytes from irradiated and unirradiated Sprague–Dawley rats were separated from white cells and plasma, lysed in water dialysed overnight, extracts were then prepared by centrifugation These extracts were incubated for 2 hr in *tris* buffer at *p*H 7 4 with either guanosine inosine, or adenosine in the presence of inorganic phosphate labelled with phosphorus-32 and magnesium chloride The detailed procedures and techniques will be described elsewhere[12] After incubation, the remaining purine nucleoside was analysed, total organic phosphate was determined, and the nature of the individual phosphate esters formed was established by means of paper chromatography[13]

The reactions studied in these incubations are represented schematically in Fig 1 and the phosphate esters actually formed from guanosine and labelled inorganic phosphate are shown by the radioautogram in Fig 2 The same phosphate esters were also obtained from incubations of inosine and adenosine Enzyme activity of erythrocyte extracts from rats irradiated with 1,000 r or 500 r to the whole body were compared with extracts from unirradiated controls A decrease in substrate utilization and phosphate ester formation was observed The results of these experiments are illustrated in Figs 3, 4 and 5

Erythrocyte extracts from rats treated with 1,000 r. showed enhanced utilization of guanosine up to 24 hr after irradiation (Fig 3), but afterwards both guanosine utilization and phosphate ester formation decreased and at 96 hr reached a minimum value and remained at this level until the death of the animals in 7–8 days Extracts from the rats treated with 500 r. showed a decrease in guanosine utilization in 24 hr after irradiation and this reduced enzyme activity continued until the ninety-sixth hour (Fig 3, these are similar to the results with the 1,000 r extracts) Afterwards, the utilization of guanosine increased again and in 240 hr the level of substrate utilization was equal to that of the controls Almost identical results were obtained with inosine, as shown in Fig 4 However, utilization of inosine by erythrocyte extracts from 500 r treated rats did not reach the level of inosine utilization by the controls until 336 hr after irradiation Experiments with adenosine utilization showed results similar to those of inosine

Significance of Results

These experiments establish that erythrocyte enzymes are affected by lethal (1,000 r) and sub-lethal (500 r) whole-body X-irradiation Also the inhibitory effect of radiation persists for seven days or longer depending on the X-ray dose Since the same enzymes are involved in the metabolism of guanosine, inosine or adenosine, one would expect radiation to influence these reactions in a similar way, as they did (Figs 3, 4 and 5)

Although nucleoside metabolism by the erythrocyte extracts from rats treated with 1,000 r was inhibited during their survival (7–8 days), the extracts from the rats treated with 500 r X-rays showed a marked inhibition for the initial interval up to 7 days after radiation This was followed by the recovery of enzyme activity by 7–10 or 14 days post-irradiation This recovery of activity suggests that with 500 r whole-body radiation the inhibition was not due to

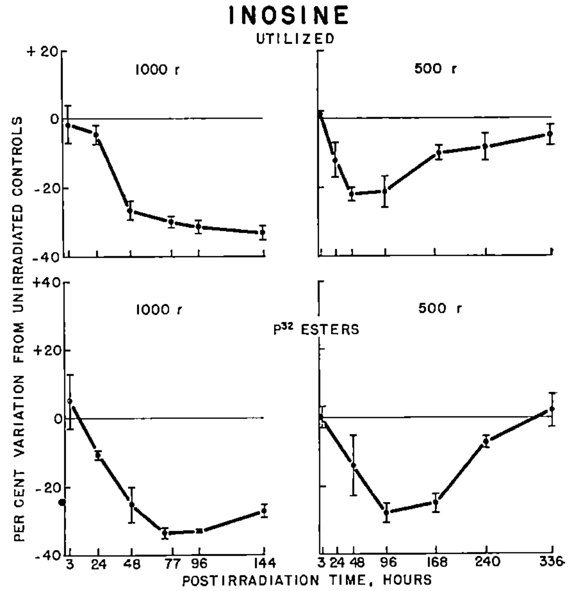

Fig 4 Comparative utilization of inosine by rat erythrocyte extracts

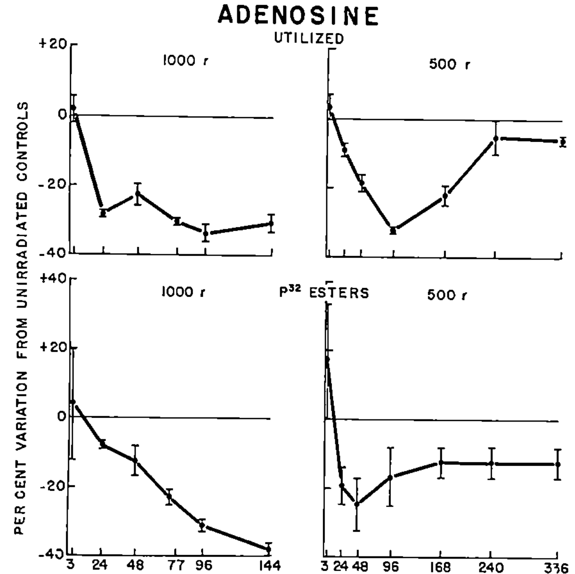

Fig 5 Comparative utilization of adenosine by rat erythrocyte extracts

irreversible protein damage, but probably to the oxidation of some essential sulphydryl groups to disulphides Since the erythrocytes contain glutathione, it is likely that the disulphide groups were gradually reduced by the glutathione during the period of recovery of enzyme activity

Although the radiation does affect the erythrocyte metabolism, how useful is this information in evaluating erythrocyte metabolism as a biological radiation indicator ? Data from Figs 3, 4 and 5 also show that the degree of inhibition, particularly for guanosine and inosine metabolism (Figs 3 and 4), is appreciably greater at 48 hr after 1,000 r irradiation than after 500 r treatment Adenosine metabolism decreased in 24 hr to a greater extent in the rats treated with 1,000 r than in those receiving 500 r The variations in erythrocyte activity described above following 1,000 r and 500 r irradiation are only the initial observations Additional data will be necessary to establish the relationship between whole-body radiation dose and degree of enzyme inhibition in erythrocyte extracts The present results suggest that the metabolism of nucleosides following radiation can serve as a gross biological indicator This information may encourage other investigators to examine the erythrocyte metabolism in other species, particularly cancer patients requiring total-body radiation treatment, in order to ascertain whether X-ray induced inhibition of rat erythrocyte metabolism also occurs in other animals, as well as in man

THE CHEMISTRY OF CLOTHING*

EVEN though clothing is one of the essential needs of human beings, it is only some fifty years since chemists and physicists, in their professional capacity, first began to give any serious thought to the subject, or even to the textile fabrics from which most clothes are made Almost everyone is, of course, interested in the æsthetics of clothing, and the fashion and style of garments often reflect the spirit of the times In the past half-century, however, quite outstanding progress has been made, not only in providing new materials for garments, but also in understanding more precisely what is required of clothing to be worn under various climatic conditions It was fitting, therefore, that at the York meeting of the British Association one session of Section B (Chemistry) was devoted to a symposium entitled "The Chemistry of Clothing"

The scope of the symposium was rather wider than its title implied, for much of the work which has been carried out is more accurately described as applied physics The principles on which the comfort and usefulness of clothing are based were discussed by Mr W H Rees of the British Cotton Industry Research Association He pointed out that in cold climates clothing acts as an insulator, thereby reducing heat lost from the body to a level which can be counterbalanced by body metabolism Since textile fibres are better conductors than air, the greater the amount of air entrapped by a fabric the more effective will it be as an insulator Rees indicated that only about 6 per cent of the volume of a blanket is occupied by fibres, the remainder being air In more compact structures this volume of air is reduced, but in most apparel fabrics it is of the order of two-thirds It is important that the entrapped air should be undisturbed and, consequently, apparel fabrics for use in windy weather should be constructed so that the wind is kept out Again, if the air in the fabric is replaced by water, as in heavy rain, the efficiency of the fabric as an insulator will fall According to Rees, therefore, clothing to be worn in wet, windy conditions should comprise "a windproof, waterproof and vapour permeable outer garment and an ample supply of inner garments having a large air content".

---

* Based on the following four papers presented at the York meeting of the British Association for the Advancement of Science
"Physical Aspects of Clothing for Comfort", by Mr W H Rees British Cotton Industry Research Association)
"The Chemical Treatment of Apparel Fabrics", by Prof C S Whewell (professor of textile technology, University of Leeds)
"Recent Advances in the Application of Cellulosic Man-Made Fibres to Clothing", by Dr H A Thomas (Messrs Courtaulds, Ltd)
"The Use of Synthetic Hydrophobic Fibres in Clothing", by Mr B Thompson (Messrs Imperial Chemical Industries, Ltd , Fibres Division)

Body heat is also lost by radiation in the far infra-red region. All textiles, whatever their colour, are virtually black bodies, with high emissivities, at least ten times as great as that of a metallic surface. To minimize radiation losses garments have, therefore, been lined with aluminium foil. The heat loss is markedly reduced, but if the layer of foil is continuous, the fabric becomes harsh and unsatisfactory and is impermeable to water vapour. By an ingenious method of perforating the film, however, it has been possible to produce in the laboratories of the British Cotton Industry Research Association a fabric which has the usual textile properties but which is extremely effective in cutting down losses by radiation.

In hot climates clothing must reflect away solar radiation and assist in keeping the body cool by the evaporation of sweat. Reflexion of radiation is clearly determined partly by the colour of the fabric, lighter coloured materials being the more effective. A white fabric will reflect away two-thirds of the incident radiation and a black one only about one-tenth. Mr. Rees has also examined the reflecting power of cotton fabrics dyed the same colour but with different types of dyes, and has found considerable differences in the infra-red. This indicates that although the reflecting power for radiations in the visible region are the same for all the fabrics, those in the infra-red are different. The chemical constitution of the dye is, therefore, important in determining the reflecting power of dyed fabrics. As would be expected, fabrics coated with aluminium foil are excellent reflectors, and if they are produced by the British Cotton Industry Research Association technique their textile properties are not impaired. In addition to being good reflectors, hot weather garments should also assist in the evaporation of sweat, and those worn next to the skin should, therefore, be absorbent and of open structure.

Modern clothing must have many characteristics other than that of being comfortable to wear. It must be æsthetically satisfying and must often have specific properties such as being fireproof, lustrous, mothproof or waterproof. In addition it must retain its appearance and essential properties during wear and after being washed or dry-cleaned. The necessity for garments to retain their essential properties throughout their life is becoming increasingly important and was stressed several times during the symposium.

Although some garments are made from skins, leather, felt and plastics, most are made from knitted, woven or bonded textiles. Fabrics available to the clothing manufacturer may contain both natural and man-made fibres. Garment manufacturing has been, however, largely based on natural fibre fabrics, but with the advent of man-made fibres, the resources of the clothing designer have been greatly increased, for there is an ever-growing production of new fibres and fabrics with interesting and novel characteristics. It was clearly not possible to discuss in the symposium new developments in all types of synthetic fibres and attention was concentrated upon specific fibre types. It must be stressed, however, that progress in the production of other fibres, for example, the acrylics, the polyolefines, and those based on fully acetylated cellulose, has been equally rapid. The development of man-made fibres has made possible the production of fabrics and garments with performance characteristics formerly considered to be unattainable. Of particular importance has been the production of fabrics which are light in weight but yet are strong and durable, and of fabrics which are easily washed and do not require ironing to restore their attractive appearance. These developments have, of course, stimulated research in the treatment and modification of fabrics made from natural fibres so that these materials also can be given some of the attractive characteristics of fabrics made from the newer fibres.

The man-made fibres can be divided into two groups—those which absorb considerable amounts of moisture, for example, viscose rayon, and those which do not, such as 'Terylene' and nylon.

Older forms of viscose rayon had several defects but now a wide range of improved regenerated cellulose fibres can be obtained. It is well known that fibres made by the viscose process have a 'skin and core' structure. The ratio between the amounts of skin and core may, however, be altered by controlling the conditions of xanthation and coagulation, and other desirable properties can be given to the filaments by stretching them immediately after they have been formed. Some of the newer products obtained by such techniques have extremely interesting properties. For example, fibres composed entirely of 'skin' are exceptionally tough and resistant to abrasion wet or dry, being stronger than cotton when wet. Filaments which are all core are obtained by spinning into a solution of ammonium sulphate and stretching the filaments by 50–100 per cent. These filaments are characterized by high strength and low extensibility when wet and are useful for making fabrics which do not shrink or stretch when they are washed. Moreover, by adjusting the spinning conditions so that one side of the fibre has a thick skin and the other a thin skin, asymmetric fibres are obtained. Because of the different swelling properties of the two sides, these fibres are crimped, and even if the crimp is pulled out during processing it will reappear on afterwards wetting the fibre. Provided that appropriate stable pigments can be ground sufficiently finely to prevent blocking the holes in the spinnerets, 'spun dyed' fibres can be produced by almost any spinning process by incorporating the pigment in the dope before it is extruded. The spun-dyed viscose rayons have been found to have some unexpected properties, for not only are the colours very fast to repeated washing and to exposure to bright sunlight, but the dispersed pigments also protect the fibre from photodegradation and deterioration in industrial atmospheres.

The introduction of the hydrophobic apparel fibres was a great step forward in textile science and technology. As Mr. A. B. Thompson pointed out, a good textile fibre must be soft without being too extensible, that is to say, it must be intermediate between a glass and a rubber. It must be elastic rather than plastic, although a plastic state is needed to ensure a satisfactory response to ironing and pressing which are essential in garment making, and often for the subsequent care of apparel fabrics. Natural fibres meet the latter requirements because they can be made plastic by application of heat and moisture. The hydrophobic fibres are much less affected by moisture and consequently retain their elasticity during use, and to achieve the plastic state heat is necessary. In general, therefore, the elastic state required in use and the plastic state needed for ironing, etc, are quite distinct This separation of the semi-flexible elastic state required in use from the more flexible plastic state needed for shaping and pressing enables garments made from the hydrophobic fibres to retain their smart appearance during wear and to be pressed or creased permanently when required

Each natural or man-made fibre has its own characteristics Many apparel fabrics are therefore made from blends of different fibres, the blend being selected so that advantage is taken of the desirable properties of each of the components Of particular significance is the blending of hydrophobic and hydrophilic fibres to produce fabrics which are light, durable, and easily cared-for, but yet comfortable to wear

Almost all fabrics are improved by suitable chemical treatment The changes brought about must, however, be 'permanent' Processes of this type were discussed by Prof C S Whewell, emphasis being laid on developments in the production of crease-resistant, 'drip-dry' and 'minimum-care' fabrics, the permanent pleating of wool fabrics, methods for obtaining textile fabrics which do not shrink or expand when they are washed, and the production of fabrics which are permanently mothproof, fireproof and waterproof

The four papers presented at the symposium formed a useful indication of some of the important trends in the production of better apparel fabrics and garments The craft of the tailor and the cloth designer is now being supplemented by the skill and resources of the scientist This combined approach to the problems associated with clothing is comparatively new, but the success which has so far been achieved is ample proof of the value of the collaboration The opportunities for research and development in this field are indeed exciting Perhaps a future meeting of the British Association will be the occasion on which the results and achievements will be discussed C S WHEWELL

RESEARCH IN THE ANTARCTIC DURING 1960

British Programme

THE Falkland Islands Dependencies Survey maintains a number of permanent scientific stations within the Falkland Islands Dependencies sector of the Antarctic Many of these have been in continuous occupation since 1944 During the International Geophysical Year they played their part with the stations of other nations in the general co-ordinated plan At the end of 1958, the Royal Society station at Halley Bay was handed over to the Survey and will continue to work like that of the other stations of the Falkland Islands Dependencies Survey, into the indefinite future

The main geophysical stations are at the Argentine Islands and Halley Bay, the two being separated by about 1,000 miles At both, daily upper-air soundings will continue, as will the surface meteorological work which is common to all bases except Port Lockroy Fluxplates and solarimeters will be in use for the study of radiation balance, and both stations will continue ozone observations using the Dobson spectrophotometer

The ionospheric work at Port Lockroy, only 40 miles from the Argentine Islands, will continue in operation, as will the recording of whistlers which forms a part of the programme initiated from Dartmouth College, New Hampshire

At Halley Bay the ionospheric equipment was not in use last year but is to be brought into commission again for 1960 On the other hand, it has been decided to abandon the seismological work there, but to continue using the Willmore short-period seismographs at the Argentine Islands

Because of the geomagnetic latitudes of the stations of the Falkland Islands Dependencies Survey, very few auroral displays are observed except at Halley Bay There an all-sky camera will continue in operation, and other studies include a small glaciological programme, observations of sea ice growth and of the measurements of marine currents

In the coming year an attempt will be made to recover cosmic spherules falling on the ice sheet, and also to obtain samples from deep within the ice Since there can be no dilution by other sedimentary materials, it may prove possible to determine a rate of deposition for this cosmic material

The other bases extend from South Georgia, where there is a purely meteorological station, through the South Orkneys and the South Shetlands along the coast of Graham Land to about lat 68° S All are manned throughout the year, the number of men varying between five and eighteen During the summer, work is to be carried out from the ships operating in the area These will be R R S *John Biscoe*, R R S *Shackleton*, H M S *Protector* and the Danish vessel *Kista Dan*, chartered for the season

John Biscoe will be committed almost entirely to relief and re-storing the bases, but it is hoped to operate a wave-recorder on board to investigate the damping effect of pack ice This is not only of academic interest, but will also be valuable when forecasting the break-up of the sea ice All bases maintain constant sea ice observations which already provide a background upon which seasonal probability charts are being built up If the protective effect of large areas of drifting pack can be assessed, ice forecasts for shipping will be materially assisted

Shackleton will be extending hydrographic surveys along the west coast of Graham Land and around the South Shetland Islands In addition, she has been fitted to tow a proton resonance magnetometer so that investigation of the Scotia Arc can be begun This work will tie up with the magnetic traverses already in progress from Hope Bay in the Trinity Peninsula area A Worden gravimeter will also be carried and put ashore for gravity observations at as many points as possible

H M S *Protector* carries helicopters and these will be used to extend the tellurometer survey where the landing of men and instruments cannot be made in any other way

The task of the *Kista Dan* is to re-establish the southernmost base on Stonington Island, which had to be evacuated last year because of bad ice conditions She will be carrying two aircraft which can be used for the transport of men and material, but if the ship is held up by bad ice conditions their first task will be to re-supply the base Then reconnaissance flights are to be made southward to select a site for a field hut which will be flown in at the end of the season Both aircraft will winter at the base and can therefore support field parties making topographical and geological surveys in the remoter regions during the early part of the 1960–61 season The *Beaver* aircraft is fitted with a Williamson vertical camera so that photographic cover can be obtained over the more inaccessible areas

Geological and topographic surveys will also continue from a number of other stations and, in addition to the glaciological programme at Halley Bay, glaciologists will be working from Hope Bay, Admiralty Bay and King George Island

In the coming year biological work will have less emphasis than in some years, but the marking and population counts of fur seals and elephant seals will continue A small project concerned with soil ecology is to begin at Signy Island Also at Halley Bay, where there is a rookery of 10,000 emperor penguins, a biologist has been appointed to continue the study of the species In particular, an examination of the endocrinology of the bird and a further collection of embryological material will be made

In each southern summer, ice conditions are different, and it is this which often hinders the planned programme Last year was a bad year, this year we hope for better things, but in any event it is certain that the only way to succeed is to keep up the pressure and be ready to take advantage of any relaxation which Nature may afford

VIVIAN FUCHS

American Programme

A STATEMENT released by the National Science Foundation gives details of grants for scientific investigations either in or associated with Antarctic regions Logistic support will again be the responsibility of a U S Navy support force under Rear Admiral David M Tyree, who has recently taken over from Rear Admiral George J Dufek The grants total 3,170,069 dollars, of which approximately one-third goes to support the meteorological programme and one-quarter to glaciological projects Greater emphasis than formerly is placed on geology, cartography and biology, which is in accord with the recommendations of the Special Committee on Antarctic Research of the International Council of Scientific Unions

Among new projects mentioned are a United States scientific expedition to the Bellinghausen Sea which will include specialists in biology, geology, cartography and oceanography

The International Geophysical Year pattern of over-snow traverse operations will be continued in Marie Byrd Land and Victoria Land Biological investigations on the ecology of the Ross Sea area and on land invertebrates of the McMurdo Sound and Hallett areas will be helped by the recently established U S Antarctic Biological Research Laboratory at McMurdo

The investigations will be spread over seven Antarctic stations of which three are fully and one jointly under the direction of the United States Co-operation with other countries in these investigations in both scientific and logistic spheres has been a notable feature of the U S Antarctic effort, and this appears likely to continue

NEWS and VIEWS

The Third Russian Space Rocket

A MULTI-STAGE space rocket was launched in the U S S R at about 02h U T on October 4 When the last stage, weighing 1,553 kgm (3,424 lb) without fuel, had reached a speed slightly less than escape speed from the Earth, an instrumented vehicle weighing 278 5 kgm (614 lb) separated from it This vehicle entered an elongated elliptic orbit which took it into the vicinity of the Moon Its nearest approach to the Moon occurred at 14h 16m U T on October 6, when it was about 7,000 km (4,300 miles) from the surface of the Moon, at selenographic longitude 137° W and latitude 12° S After leaving the vicinity of the Moon, the vehicle entered a new elliptic orbit about the Earth, with an apogee distance of 470,000 km (292,000 miles) from the surface of the Earth, attained at about 00h U T on October 11, and a perigee distance of 40,000 km (25,000 miles), attained at about 17h U T on October 18 The orbit is inclined at about 75° to the Earth's equator and the period of revolution is about 15 4 days The vehicle has been designated Earth-satellite 1959 θ The orbit of the spent rocket is not known The instrumented vehicle, which the Russians have referred to as an "automatic interplanetary station", carried apparatus to photograph the part of the Moon which is never seen from the Earth, and also apparently performed other scientific experiments, of which details have not yet been given The vehicle had radio transmitters operating on 39 986 Mc /s and 183 6 Mc /s, the power being supplied partly by chemical and partly by solar batteries

Research Association of British Paint, Colour and Varnish Manufacturers Dr L A Jordan, C B E

DR LOUIS ARNOLD JORDAN, the founder-director of the Research Association of British Paint, Colour and Varnish Manufacturers, has relinquished his appointment after thirty-three years The Paint Research Station at Teddington, at present being further extended, stands in testimony to his achievement Educated at Alderman Newton's Greencoat Foundation School, Leicester, he proceeded as a Royal scholar in 1910 to the Royal College of Science, where he was Tyndall prize-man in physics and Frank Hatton prize-man in chemistry He received the D Sc (London) in 1921 During the First World War he was concerned with explosives, and certain 'gas' problems, thence to Boots Pure Drug Co, Ltd, and later to the British Xylonite Co, Ltd, to start an investigation which resulted in the establishment of the British synthetic camphor industry From 1923 until the establishment of the Paint Research Association in 1926 he was scientific adviser to the State of Bhopal, Central India. He returned to India in 1955 at the invitation of the Government of India to inquire into matters touching the development of the lac industries. In fact, he is widely travelled (another recent journey having been to Brazil to advise on organized research in paint and related matters) and is well known internationally, for example, through his work for the Organic Coatings Division of the Applied Chemistry Section of the International Union of Pure and Applied Chemistry.

Dr Jordan has given extensive service to the Oil and Colour Chemists Association (he was president during 1947–49) and to numerous other scientific and technical organizations. He was chairman of the council of the Society of Chemical Industry during 1952–53 and medallist of the Society in 1953. As one of the Jubilee Memorial lecturers of the Society (1944) he chose as his subject "Paint, the Art and Science", reflecting his interest in the artistic as well as in the industrial and scientific aspects of paint and painting, an interest culminating in 1958 in his appointment as professor of chemistry at the Royal Academy of Arts. His work for technical education stands high in achievement and personal satisfaction. He has for long been chairman of the City and Guilds Advisory Committee on Paint Technology, and his period as a Surrey county councillor (1946–58) provided opportunities for contributions in a wider field of technical studies. He is now chairman of the governors of the Kingston Technical College, a governor of the Brunel College of Technology, and a member of the Regional Advisory Council for Technological Education for London and the Home Counties Region. He has recently been appointed to the senate of the University of London.

Botany at Hull

Prof R D'O Good

Prof Ronald Good, who has retired from the chair of botany in the University of Hull, was head of the Department of Botany from the foundation of the University College in 1928. After serving in the First World War, followed by a brilliant period at Downing College, Cambridge, he held an appointment at the British Museum (Natural History). At Hull he had much to do with the organization and equipment of his department, as well as teaching, but he has also been active as a researcher and writer. His book on the "Geography of the Flowering Plants" has had a wide circulation and is regarded as one of the chief works on the subject, while his "Handbook of the Dorset Flora" is an outstanding ecological study.

Prof N F Robertson

Dr N F Robertson, who has succeeded Prof Good, has been on the staff of the Cambridge Botany School since 1948. His interest in mycology was first aroused by Dr Malcolm Wilson at the University of Edinburgh. After graduating there in 1944, Dr Robertson was appointed a Colonial Office probationer and studied at the University of Cambridge, at Rothamsted Experimental Station and in the United States before proceeding to the West African Cacao Research Institute at Tafo late in 1946. He worked there, in collaboration with Dr A F Posnette, on insect transmission of the swollen shoot disease. Dr Robertson's first research problem at Cambridge was concerned with mycorrhizal infection of the Scots pine, and he made a notable contribution to the subject by showing that the behaviour of the mycorrhizal fungus was closely related to that of the specialized root disease fungi affecting tree crops. More recently, Dr Robertson has turned his attention to the physiology of fungal branch systems in culture, and has made what may eventually prove to be the first experimental approach to the morphogenesis of asexual spore production. With his research students, Dr Robertson has explored a much wider field, ranging from the physiology and genetics of the Fusaria in laboratory experiments to the behaviour of Fusarium wilt diseases and potato blight in the field. The University of Hull is doubly fortunate in securing Dr Robertson as professor of botany, because he has distinguished himself at Cambridge not only by his research but also as a teacher, and by the full share he has taken in other duties in the Department of Botany, where he will be greatly missed.

The World Veterinary Association

Prof W. I B Beveridge

At the recent International Veterinary Congress in Madrid a World Veterinary Association was established. The main purposes of the Association are to unify the veterinary profession throughout the world by providing a central link for national veterinary associations, and the exchange of information on matters of veterinary interest. The organs of the Association are the congress and the permanent committee.

Prof W I B Beveridge, professor of animal pathology, University of Cambridge, has been elected president of the Permanent Committee of the newly founded World Veterinary Association. He has had a distinguished career as a veterinarian who gave outstanding service to his profession in Australia and in the United Kingdom. After graduating at the University of Sydney, he was a member of the research staff of the McMaster Animal Health Laboratory in Sydney during 1931–41. During two years of that time he was the holder of a Commonwealth Fund Fellowship at the Rockefeller Institute, Princeton, and the Bureau of Animal Industry, Washington. From 1941 until his appointment as professor of animal pathology in Cambridge he worked at the Walter and Eliza Hall Institute in Melbourne. Together with Sir Macfarlane Burnet he worked on viral diseases in man and published several outstanding papers concerning cultivation of viruses. In Cambridge, Prof Beveridge's researches are mainly concerned with viral diseases of respiratory systems in animals. Unfortunately, his scientific work there was very much interrupted by administrative duties associated with the establishment of the new Veterinary School which was opened by H M the Queen and the Duke of Edinburgh in October 1955. He is the author of the book, "The Art of Scientific Investigation". Both on account of his outstanding reputation and his interest in international co-operation, he will be a most welcome president of the newly founded World Veterinary Association.

Amendments to the U S Atomic Energy Act

In a report by the United States Atomic Energy Commission (The Indemnification of Atomic Energy Activities and Operations of Advisory Committee on Reactor Safeguards, 1958–59. Report of the Joint Committee on Atomic Energy on Operations under Section 170 of the Atomic Energy Act of 1954 as Amended. Pp iii + 74. Washington, D C: United

States Atomic Energy Commission, 1959), details are given of the proposed regulations approving the form of nuclear energy liability insurance policies and Commission indemnity agreements Amendments to the indemnity proposals of the Atomic Energy Act, 1954, which it is proposed to submit to Congress, exclude liability for damage to property located at the site of, or used in connexion with, the licensed activity, and would authorize the Commission to fill a gap for a sufficient period of time in which to give the licensee reasonable opportunity to furnish the required protection The Commission is also studying the possible gaps resulting from the 'common occurrence' provision, and has entered into a contract for a study of criticality hazards as part of its continuing study of the problem of extending indemnity to materials licensees As regards foreign liability problems, the efforts of the Commission have been directed primarily to encouragement and support of the efforts of other governments to enact their own legislation and effect international arrangements

Scientific Staff in New Zealand

DURING the past twelve months, six officers of the Ruakura Animal Research Station in New Zealand have resigned to accept posts in Australia All have received an increase of salary of £A500 to £A1,000 on taking up their new posts The maxima attached to their new position in Australia is, in all cases, about twice that offered for the positions they vacated in New Zealand Another 25 individuals have resigned from Government laboratories or science departments of New Zealand universities during the past three years to accept overseas posts, mainly in Australia This figure does not include graduates in science who have gone overseas for advanced training

Both Government departments and the universities experience great difficulty in replacing the losses of scientific staff with persons of the desired quality The Soil Bureau of the Department of Scientific and Industrial Research has been seeking pedologists for some time without success, and advertisements for mycologists, entomologists, mathematicians and physiologists have failed to attract any applicants or applicants of the desired qualifications and calibre Whereas five years ago there were usually a number of highly qualified applicants for each vacancy from which selection could be made, the position has changed so that to-day only one or two such applicants and sometimes none at all apply for advertised positions

Scientific Research in British Universities

"SCIENTIFIC Research in British Universities, 1958–59", based, as in previous years, on material collected by the British Council from heads of departments of the universities, who are alone responsible for the entries, now runs to 446 pages (pp xii+446 London H M Stationery Office, 1959 25*s* net) These brief notes on scientific research in progress during the 1958–59 session indicate the nature of the projects in sufficient detail to show the scope of the research Entries are arranged in alphabetical order of university or university college, and under each institution the arrangement is alphabetically by subject The head of the department is named, with those permanent members of staff actually engaged in supervising research There are alphabetical name and subject indexes

Registration of Scientific and Technical Persons, 1958

FRESH and renewed registrations for all professional classes covered by the Technical and Scientific Register of the Ministry of Labour, with the exception of mathematicians and physicists, steadily increased during 1958, according to the Ministry's annual report At the end of December, registrations, including those seeking a change as well as those employed, were 29 per cent higher than in December 1957, a significant part of the increase comprising registrations of men in the middle age groups seeking better positions before age restricted their prospects and from ex-regular members of the Forces who had retired or anticipated premature retirement At December 8, 1958, of 4,556 on the register, compared with 3,538 in 1957, 1,326 were unemployed Premature retirements from the Services reached a peak during the year, but the Regular Forces Resettlement Service, set up by the Ministry, received encouraging support from industry and commerce, and there was no significant increase at the end of the year in the number of such applicants unemployed The report also directs attention to the establishment in July 1958 by the British Employers' Confederation, the Trades Union Congress and the boards of the nationalized industries, of the Industrial Training Council in accordance with the recommendation of the Carr Committee This Council has undertaken as its first task the encouragement of industry generally to take advantage of the opportunities provided by the 'bulge' of school-leavers to expand apprenticeship schemes and other forms of training Thirty-two appointments were made to the general factory inspectorate, and with five applicants awaiting appointment, the number of vacancies at the end of the year was nine Five additional appointments were made to the Engineering and Chemical Branches of the inspectorate On the advice of the National Advisory Committee on the Employment of Older Men and Women, the Ministry is discussing with the Department of Scientific and Industrial Research and the Medical Research Council arrangements to ensure co-operation between the Ministry, industry and research organizations and to stimulate research into problems of employment of older workers

Rubber Research

THE twenty-second "Annual Report on the Progress of Rubber Technology" covers the progress of rubber technology during the year 1958 (edited by Dr T J Drakeley Pp ix+125+xii Cambridge W Heffer and Sons, Ltd , 1959 Published for the Institution of the Rubber Industry) The report contains twenty-three sections, by different contributors, covering all aspects of the technology of rubber-like materials, both natural and synthetic, ranging from surgical goods to the use of rubber in roads The report also includes sections on historical and economic aspects, planting and production of natural rubber, fibres and fabrics used in conjunction with rubber, compounding ingredients and, for the first time, a separate section on the manufacture of synthetic rubbers The introduction of this latter section is timely since 1958 saw the opening in Italy, Germany and the United Kingdom of the first major European plants for the production of general-purpose synthetic rubber Synthetic elastomers are now firmly established as a large and important part of the rubber industry Already approximately 65 per cent of American new-rubber consumption consists of synthetics; the corresponding figure for the rest of the world (excluding Communist countries) is 25 per cent, but this is likely to increase with the opening of the new plants. The year does not appear to have produced any outstanding new technical developments but rather a steady improvement of materials and techniques. The report contains more than one thousand references to scientific and technical publications, although, as is inevitable in a work of this kind, there is some overlapping from section to section.

Aerial Photographic Exhibition of Quarries and Mines

A SPECIAL exhibition of aerial photographs of quarries and mines opened at the Geological Museum, Exhibition Road, London, S.W.7, on October 15. Admission is free. The exhibition will remain open for several months. The photographs show past and present surface aspects and effects of quarrying and mining in the United Kingdom, and illustrate the great variety of useful rocks and minerals found in Britain. All the photographs are from the Cambridge University Collection, an extensive library of air photographs specially selected to meet needs of teaching and research. They have been taken during recent years by Dr. J. K. S. St. Joseph, curator in aerial photography at Cambridge, from aircraft of the Royal Air Force on training flights.

Petroleum Industry in Great Britain

THE Petroleum Information Bureau has published under the title "U.K. Petroleum Industry Statistics relating to Consumption and Refinery Production, 1957 and 1958" (Pp. 10. London: Petroleum Information Bureau, 1959) figures covering all petroleum products, whether imported or from indigenous sources, as well as substitutes such as benzole and hydrogenated spirits. Refinery production figures do not count further treatment of finished products for special grades. The figures relate to 1957 and 1958, in which deliveries and consumption of petroleum products totalled 24,784,586 tons and 31,065,629 tons, respectively.

New Journal of Glass Technology

MORE and more problems in the physics and chemistry of glasses are being investigated in laboratories all over the world. At present the results are published in many non-specialized journals and the time has come to provide a vehicle for these papers. The Society of Glass Technology has therefore decided that from February 1960 its *Journal* should be published in two parts. These will be called *Glass Technology* and *Physics and Chemistry of Glasses*. Both journals will contain papers, abstracts, communications to the editor and book reviews. Arrangements are being made with the Abstracting Board of the International Council of Scientific Unions to ensure that papers published in these new journals will be abstracted as widely as possible and also that the abstract sections will be comprehensive. *Glass Technology* will contain reports of applied science in the glass industry, and subjects considered suitable include: control of batch compositions; corrosion of refractories; design, operation and performance of furnaces; methods of chemical and physical testing; melting processes; statistical analysis of industrial experimentation. In *Physics and Chemistry of Glasses* will be published reports of original studies of the physics and chemistry of glasses, both experimental and theoretical. Possible subjects include: electrical properties; infra-red absorption; relaxation processes; thermodynamics of the glassy state; viscosity; X-ray diffraction. Copies of the Society's notes for authors are available from Prof. R. W. Douglas, Society of Glass Technology, Thornton, Hallam Gate Road, Sheffield 10.

Plant Nematology

IT is now recognized that eelworm diseases are among the most important problems in plant health and there has been a rapid increase in the study of plant parasitic nematodes in all countries where the growing of plants has become an organized industry. Unfortunately, there is a shortage of trained specialists in nematology and of introductory literature on the subject. The Ministry of Agriculture's new Technical Bulletin No. 7 (Pp. vii+175+12 plates. London: H.M. Stationery Office, 1959. 9*s*. 6*d*. net) provides a general introduction and is based on the lectures given at a special training course held at the National Agricultural Advisory Service regional headquarters, Bristol, in 1956. It also reviews the more important nematode problems in British agriculture and is in part designed as a companion volume to Technical Bulletin No. 2 (Laboratory Methods for Work with Plant and Soil Nematodes). Although primarily designed for nematologists it should also be of interest to agricultural entomologists, plant pathologists and others who have to advise on eelworm problems and also to students and teachers of zoology, agriculture and parasitology. It contains 21 articles by research and advisory workers, arranged in six main sections covering the general structure and classification of nematodes, the more important genera, several practical and research problems with cyst-forming eelworms, control and cultural studies.

Sea Fisheries Research in East Africa

THE annual report for 1958 of the East African Marine Fisheries Research Organization (pp. 20. Nairobi: Government Printer, 1959. 4*s*.) is one that reflects great credit on the small staff at Zanzibar. Research on the fish and fish-stocks of the Indian Ocean, first at Mauritius and now at Zanzibar, has been the post-war concern of the director, Dr. R. H. Wheeler, and it is good to learn from him that the phase during which it has been of first necessity to identify species is passing. In spite of the need to do systematic work, Dr. Wheeler, operating from Mauritius with a small converted fishing vessel, had already discovered a large and potentially rewarding line fishery in the neighbourhood of Seychelles Banks. The same vessel was transferred to Zanzibar, but during 1957 it was replaced by a large and more serviceable trawler, the *Manihine*. Among other tasks assigned to *Manihine* was floating long-line fishing for yellow-fin tuna and striped marlin. Using seven miles of line and two hundred and fifty hooks on or below the thermocline at 50–70 fathoms, heavy catches were made. These results are most encouraging for all those who wish to see the Colonies, Dependencies and emerging Commonwealth countries of Africa break into the oceanic resources of pelagic fish now so largely in the hands of the Japanese.

Translocation of Amino-Acids

THE translocation of carbon-14-labelled amino-acids and amides in the stems of young soyabean plants has been investigated by C D Nelson and P R Gorham (*Canadian J Bot*, 37, 3, 431 (1959)) with the following results In all, the translocation of each of seven amino-acids and three amides was measured for periods of 5 minutes or less after introduction through the cut petiole of a primary leaf The compounds used were asparagine, urea, glutamic acid, glutamine, glycine, norleucine, arginine, serine, alanine and aspartic acid During the short times of these experiments it was found that each compound was translocated downwards as such The amount of carbon-14 in the stem decreased logarithmically from the point of introduction Each compound was translocated with unchanged velocity past a short section of stem killed with steam There was no translocation of aspartic acid through a stem that had an entire internode killed with steam Potassium cyanide (10^{-2} *M*) did not inhibit the velocity of translocation of any of the compounds although the logarithmic pattern of distribution of arginine was altered The minimum velocity of translocation was different for each compound and varied between 350 cm per hr for asparagine and 1400 cm per hr for aspartic acid The authors have also reported on the physiological control of the distribution of these substances (*Canadian J Bot*, 37, 3, 439 (1959)) From the point of introduction, translocation of each amino-acid or amide was mainly downward towards the root, very little was translocated upward Both excision of the roots and chilling decreased the velocity of downward translocation of aspartic acid, indicating that the roots exert a strong 'demand' which favours translocation in a downward direction more than an upward direction in the stem

Volcanic Activity on the Moon

In a brief article, N A Kozyrev (*Priroda*, 3, 84, 1959) describes his observations of the Moon since 1955 and provides a critical examination of the records of the Alphonse crater on November 3, 1958 In his opinion the spectrographic evidence suggests strongly that an eruption of volcanic ash did take place on that date on the Moon This eruption was followed by the emission of gases containing C_2 molecules

Astronomische Gesellschaft Star Catalogues

Between 1868 and 1908 the Astronomische Gesellschaft organized the production of a catalogue of all the stars brighter than the ninth magnitude in the northern sky A dozen observatories shared in this work, the observations being made visually using meridian circles It was later decided to repeat the whole programme photographically, and new observations were obtained during the years 1928–32 The Hamburg Observatory photographed the sky north of +20° declination, the Bonn Observatory that from +20° to −2° Observations of 14,000 reference stars were made at several observatories The measurement of the photographs and the reduction of the measures have been in progress since 1932, and publication of the results began in 1951 The results are contained in a fifteen-volume catalogue, and the last five volumes of this catalogue have recently been published The catalogue contains the positions of 180,000 stars down to magnitude 11 5 No proper motions for the stars were deduced because it was impossible to free the earlier catalogues from systematic errors The homogeneity of the results of this large undertaking represents one of its most important features, and the catalogue is, and will remain, a landmark in positional astronomy The catalogue is known as the *AGK*2

It has been decided to repeat the whole catalogue with a mean epoch of about 1960 18,000 secondary reference stars are being observed at various observatories, the photography is being performed at Hamburg and 1,939 plates will be required It is hoped to have positions and proper motions for all the 180,000 stars by 1965 This new catalogue, the *AGK*3, will enable astronomers to determine the systematic errors of old catalogues, connect the proper motions of the bright stars with those of fainter stars measured relative to the extragalactic nebulæ, and provide much data for geodetic purposes

Courses in Chemical Engineering

A new pamphlet, "Scheme for a Full-time Course in Chemical Engineering" (pp 16 London Institution of Chemical Engineers, 1959 2*s*), is a revised version of the "Scheme for a Degree Course in Chemical Engineering", originally issued in 1944, and takes account of current developments in teaching chemical engineering at technical colleges The course covers three years, and although in the first two years most of the time is spent on physical, organic and inorganic chemistry, the physics of solids, electricity, and mathematics, fluid mechanics, heat and mass transfer, the design and construction of process plant, power thermodynamics and engineering drawing are introduced at this stage and not left until the final year In this year the course comprises fluid and particle mechanics, heat and mass transfer, separation processes, applied chemical thermodynamics and kinetics, fuels and combustion and design problems Practical experience in works is regarded as an essential adjunct to the course, and the economic aspect should be introduced into lectures on chemical process principles in the first year The course should not be so rigid as to preclude transfer to chemical engineering in the earlier years by students who have commenced studies in a cognate faculty

Talanta Medal

The board of editors of *Talanta* announces a new award to be known as the Talanta Medal The publishers, Pergamon Press, are providing the funds for this Medal, which will have a value of 100 guineas and which will be awarded for outstanding contributions to analytical chemistry The Medal will not normally be awarded more frequently than once a year, but no attempt will be made to award it at any stated intervals This award will be either to analytical chemists who are responsible for major developments in the subject or to scientists whose work is judged to have contributed in a substantial way to the developments in the field of analytical chemistry Applications should be sent to the editors of *Talanta*, c/o Pergamon Press, 4–5 Fitzroy Square, London, W 1

Perkin Centenary Trust

The programme of awards for the year 1960–61 will include one Perkin Centenary Fellowship, valued at not less than £600 a year, which is available to a graduate for advanced studies, and two Perkin Centenary Scholarships at £300 a year, which are intended to give young persons employed in the industries concerned with the manufacture or the application of colouring matters the opportunity of full-time education at a university or technical college Applications are invited for the Perkin Trust Travel Grants from teachers concerned in the study of any aspects of the manufacture or applications of colouring matters at a university or technical college or other institute The purpose of the grants is to enable teachers to make short visits to comparable institutions overseas to widen their experience The secretary to the trustees is Dr J R Ruck Keene, to whom inquiries relating to awards should be addressed, at the Chemical Society, Burlington House, London, W 1

Harkness Fellowships of the Commonwealth Fund

THE awards bearing since 1925 the title Commonwealth Fund Fellowships were renamed in 1959 the Harkness Fellowships of the Commonwealth Fund All Fellowships are tenable in the United States and are offered, in separate series, to candidates from the United Kingdom, Australia and New Zealand, and Western Europe The Fund, an American philanthropic foundation, believes that international understanding may be promoted by opportunities for education and travel in the United States Thirty Fellowships are offered in 1960 to candidates from the United Kingdom who are British subjects and are either graduates or have experience in government service, the professions, the creative arts, journalism, branches of business or industry Forms of application, which must be returned before December 1, can be obtained from the Warden, Harkness House, 38 Upper Brook Street, London, W 1, from whom further details can be obtained

British Institution of Radio Engineers Awards

THE Council of the British Institution of Radio Engineers has announced the award of a number of premiums for outstanding papers published in the Institution's *Journal* during 1958 the senior award, the Clerk Maxwell Premium, goes to Mr C Powell and Mr D A Hendley (Decca Navigator Co , Ltd) for the paper, "Dectra A Long Range Radio Navigation Aid" , Heinrich Hertz Premium to Mr K Foster (Cossor Radar and Electronics, Ltd) for the paper, "The Characteristic Impedance and Phase Velocity of High-*Q* Triplate Line" , for the third successive year the Sir Louis Sterling Premium to Dr A van Weel (Philips, Eindhoven) for his paper, "Design of Detector Stages for Signals with Symmetrical or Asymmetrical Side-bands" , Sir J C Bose Premium to Dr B Ramachandra Rao, Dr M Srirama Rao and Mr C Abhirama Reddy, from Andhra University, South India, for their paper entitled "Magneto-ionic Fading in Pulsed Radio Waves reflected at Vertical Incidence from the Ionosphere" , Brabazon Premium to Prof D G Tucker, Dr V G Welsby, Mr R Kendall and Mr D E N Davies for their associated papers entitled "Electronic Sector Scanning" and "Radar Systems with Electronic Sector Scanning" , and Marconi Premium to Dr Morton B Prince and Mr M Wolf, of Hoffman Electronics, Inc , Evanston, Illinois, U S A , for their paper "New Developments in Silicon Photo-voltaic Devices"

Volume Fifty of the "Large Soviet Encyclopædia" ("Bolshaya Sovietskaya Enziclopediya")

THIS volume, part of a set of fifty, could not be sold separately when it was originally issued In 957, however, a special edition of 300,000 copies was printed, which could be sold separately Thus this finely printed and bound volume of 764 pages can be purchased in Britain for the sum of £2 It contains summary articles or reviews of all aspects of the Soviet Union and thus it is an invaluable reference book for anyone interested in this subject It is illustrated by a large number of folding and text maps, plates, text figures and tables Scientific workers will be interested in the following chapters 3, geography, geology, climate, soils, vegetable and animal worlds of the Soviet Union , 4, population , 5, history , 9, economics , 12, education , 15, science Chapters which follow deal with literature, arts and other subjects Chronological tables and a name index are placed at the end

Announcements

DR A J P MARTIN, of Elstree, Herts, Dr R L M Synge, of the Rowett Research Institute, Bucksburn, Aberdeenshire, and Dr A T James, of the National Institute for Medical Research, Mill Hill, have been awarded John Price Wetherill medals of the Franklin Institute for their development of gas–liquid (partition) chromatography

AT the sixth annual general meeting of the Association of Clinical Biochemists, held at the Royal College of Surgeons, London, on October 3, the following officers were elected *President*, Dr C P Stewart , *Chairman*, Dr A L Latner , *Hon Treasurer*, Dr J H Wilkinson , *Hon Secretary*, Dr A L Tárnoky, Royal Berkshire Hospital, Reading

A REGIONAL training course for laboratory technicians sponsored jointly by the University Institute of Chemistry, Lahore, and the Unesco South Asia Science Co-operation Office will be held at the University Institute of Chemistry, Lahore, Pakistan, during November 23–December 19 Inquiries should be addressed to the Unesco South Asia Science Co-operation Office, 21 Curzon Road, New Delhi, India

IN a written answer in the House of Commons on July 30, the Chancellor of the Exchequer stated that, to assist the Government in making a review of the control of public expenditure, he was appointing a small group to make a full examination of the whole problem, in consultation with all major departments, and to formulate proposals Lord Plowden would take general charge of this work, and besides senior officials from departments, including the Treasury, the group would include two or three persons from outside the Government service

THE Chemical Society has announced that applications for Research Fund grants should be submitted not later than November 14 Further information can be obtained from the General Secretary, Chemical Society, Burlington House, London, W 1

THE Institute of Physics is organizing a conference during November 13–14 on "Structure Analysis and Experimental Techniques" The conference is to be held at the Institution of Civil Engineers, Great George Street, London, S W 1 Further information can be obtained from Dr P T Davies, "Shell" Research, Ltd , Thornton Research Centre, P O Box 1, Chester

ERRATUM In the communication entitled "Prevention of the Onset of Seed Dormancy by Gibberellic Acid", by Dr M Black and J M Naylor, in *Nature* of August 8, p 468, in the legend to Fig 1, for "2 replicates each comprising 50 embryos" read " 2 replicates each comprising 50 caryopses"

SCIENTISTS IN THE PUBLIC SERVICE IN BRITAIN

SPECIAL PROMOTIONS

FURTHER posts have been created in the Civil Service as in previous years under provisions included in the White Paper on the Scientific Civil Service (Cmd. 6679, 1945) to provide for the promotion of individual research workers of exceptional merit. The promotions were effective from July 1, and include the following.

Deputy Chief Scientific Officer

Dr. J. S. Hey joined the Army Operational Research Group in 1940, becoming its head in 1949. In 1952 he formed a research section of what is now the Royal Radar Establishment. Both before and since going to Malvern, he made exceptionally distinguished pioneering contributions to radio astronomy which were the basis for his D.Sc. His work for the Ministry of Supply has also included important contributions on the mechanism of electromagnetic scattering and the ionization associated with discontinuities in hypersonic gas flows, all marked by originality and simple elegance in experimental technique. He is a Fellow of the Physical Society and the Royal Astronomical Society, has served on the Council of the latter and was this year awarded the Eddington Medal. He serves on Commissions of the International Astronomical Union.

Dr. H. G. Hopkins was at the Royal Aircraft Establishment during the war years, working primarily on the theory of elastic stability and of stress distribution in aircraft structure. In 1946 he returned to academic teaching and research. He joined the Armaments Research Development Establishment in 1954 and has been concerned with damage to structures, camouflet and crater formation in soils and dynamic studies in metal plasticity.

Mr. D. H. Sadler is superintendent of H.M. Nautical Almanac Office, the work of which is divided between the highest theoretical and numerical requirements of fundamental astronomy and celestial mechanics and the practical requirements of astronomical navigation. It was largely due to him that the Royal Air Force had such excellent almanacs and tables during the Second World War. Since then the provision for astronomical navigation, both at sea and in the air, has been much expanded and is now completely unified with that in the United States. Mr. Sadler has contributed much to the theoretical side of navigation and has been awarded the premier awards of both the British (Gold Medal, 1957) and the American (Thurlow Award, 1948) Institutes of Navigation; he was president of the British Institute during the period 1955–56. He is at present general secretary of the International Astronomical Union, and he was secretary of the Royal Astronomical Society during 1939–47. During the Second World War he also directed the computational side of the highly successful Admiralty Computing Service.

Senior Principal Scientific Officer

Mr. J. M. Craddock is serving in the assistant directorate of Dynamical Research in the Meteorological Office of the Air Ministry and is engaged on research into the problem of long-range weather forecasting.

Mr. F. J. Bradshaw, of the Metallurgy Department, Royal Aircraft Establishment, is a fertile research worker on the physics of metals.

Mr. A. G. Earl, of the Guided Weapons Department, Royal Aircraft Establishment, is a research engineer who has studied the fuel system and control systems of guided missiles.

Dr. H. Kolsky, of the Armament Research and Development Establishment, after a distinguished outside career devoted mainly to the mechanics of solids, has recently joined Dr. Hopkins at Fort Halstead.

Dr. E. H. Mansfield, of the Structures Department, Royal Aircraft Establishment, has studied mathematical aspects of aircraft structural research, most recently in connexion with the effects of kinetic heating.

Dr. A. H. Cook (National Physical Laboratory, Standards Division) is primarily engaged in the accurate measurement in absolute terms of certain physical quantities and constants.

Mr. C. G. Giles (Road Research Laboratory) has conducted research aimed at finding ways of reducing the number of road accidents due to skidding.

Dr. A. C. Hulme (Ditton Laboratory of the Food Investigation Board, now of the Agricultural Research Council) works on various aspects of the biochemistry and physiology of apples and other fruits, especially on biochemical changes in respiration during storage.

Mr. A. Silverleaf (National Physical Laboratory, Ship Division) is in charge of the group responsible for research and design in the fields of ship propulsion, cavitation and vibration.

Dr. E. H. Rhoderick joined the Services Electronics Research Laboratory in 1955 and is working at present on very fast switching for computers using superconductors.

Mr. S. B. Kendrick, of the Naval Construction Research Establishment, is an authority on the design of submarine pressure hulls.

Similar promotions have been made by:

(1) U.K. Atomic Energy Authority

Deputy Chief Scientific Officer

Dr. G. E. Bacon spent the war years at the Telecommunications Research Establishment on the development of ground radar equipment, particularly aerial systems. In 1946 he joined the Atomic Energy Research Establishment at Harwell, where he has worked on the application of X-ray and neutron diffraction to the study of the solid state. He is known especially for his work on the structural crystallography of graphite and for neutron studies of hydrogen bonds and thermal motion in hydrated and organic substances.

Dr W B Thompson took up a Harwell Senior Fellowship in 1950 and is now the senior theoretical physicist working on the problems of fusion reactors His section of the Theoretical Physics Division carries out mathematical investigation into the stability of high-current gas discharges, on the rates of loss of heat from gases at temperatures of more than a million degrees centigrade, and on the effects of magnetic fields on the bulk and particle motions of highly ionized plasmas The work includes interpretation of the many fundamental experiments in this field carried on in all parts of the world and assessment of its significance to the building of a theory good enough to allow final success in the fusion reactor field

Mr W Walkinshaw is one of Britain's leading particle accelerator theoreticians, joining the Telecommunications Research Establishment in 1940 where he carried out theoretical research on radar and on high-energy particle accelerators He has worked at the Atomic Energy Research Establishment, Harwell, since 1951 His section of the Theoretical Physics Division is very closely associated with the Rutherford Laboratory of the new National Institute for Nuclear Research, and has been engaged principally on the large 7,000 MeV proton synchrotron which is still under construction In addition to this continuing task, the group is charged with the duty of conceiving new types of accelerating machines and specifying designs for other machines of tested types

Senior Principal Scientific Officer

Dr K W Bagnall is at Harwell in charge of a section of the Radiochemistry Branch of the Chemistry Division which is concerned with research into the chemistry of the actinide and other heavy elements At present, the main interest is in protactinium

Dr A M Lane is part of the team of theoreticians whose task it is to ensure that the Atomic Energy Authority is fully armed with the most up-to-date and reliable knowledge of nuclear physics

(2) Agricultural Research Council
Deputy Chief Scientific Officer

Dr R L Mitchell joined the staff of the Macaulay Institute for Soil Research, Aberdeen, in 1937 He is deputy director of the Institute and head of the Department of Spectrochemistry Dr Mitchell has been responsible for the development of spectrochemical methods applicable to the analysis of soils, plants and related materials, involving the evolution of techniques and equipment for arc, spark and flame emission methods The chemical concentration technique is now quite widely used throughout the world and many overseas workers have visited the Macaulay Institute to study the spectrochemical methods developed by Dr Mitchell and his co-workers More than sixty publications describe methods employed and the valuable results obtained in the study of trace element relationships in soils and plants and of the geochemical background to their occurrence The work of his department also includes the use of infra-red and ultra-violet absorption methods for the examination of organic and inorganic soil constituents

Senior Principal Scientific Officers

Dr N J Berridge is a member of the staff of the National Institute for Research in Dairying and is well known as an authority on rennin

Dr Alan Robertson, of the Agricultural Research Unit of Animal Genetics, Edinburgh, is widely recognized as one of the most successful students of the rapidly expanding subject of population genetics

Dr V P Whittaker, of the Agricultural Research Institute of Animal Physiology, Babraham, Cambridge, has done outstanding research in the cholinesterase field

(3) Development Commission
Senior Principal Scientific Officer

Dr J W G Lund is in charge of the Freshwater Biological Association and has made important contributions to the understanding of the factors which, by controlling the annual phytoplankton cycle, determine the fertility of lakes and reservoirs

(4) Nature Conservancy ·
Senior Principal Scientific Officer

Mr J G Skellam is head of the Biometrics Branch of the Nature Conservancy, contributing to mathematical biology, and in particular to theoretical study of population dynamics and statistical ecology

CONCEPTION OF EVOLUTION

MEETING IN PARIS

The Muséum National d'Histoire Naturelle celebrated on June 5 the anniversaries of the "Precurseurs et Fondateurs de l'évolutionnisme—Buffon, Lamarck, Darwin" the 250th anniversary of Buffon's birth, the 150th anniversary of the publication of Lamarck's "Philosophie zoologique", and the centenary of Darwin's "Origin of Species". The meeting was held in the famous Grand Amphitheatre, planned during Buffon's administration, and which, reconditioned about four years ago, is again used for its original purpose A large and distinguished audience including many famous scientists, some of whom have long been retired, was present

Prof Roger Heim, director of the Museum, gave an opening discourse, first summarizing the pre-Buffon period with his customary clarity and grasp of essentials If in this he appeared to stress the views of naturalists of the old Jardin du Roi it was inevitable, for naturalist-philosophers were almost confined to France at the time—and to the Garden There were clear statements about transformism before Buffon, and equally there was a belief in the fixity of species after him An upholder of this was Bosc, one of the founders of the Linnean Society of Paris in 1788, the same year as that of London was started One of the first acts of the society was to petition for the erection of monuments in the Garden to the memory of famous scientists, beginning with that of Linnæus, later destroyed by *sans-culottes*.

Prof. Jean Piveteau, of the Sorbonne, a well-known authority on Buffon, gave an account of his personality with particular reference to his ideas on evolution, how they developed and how, at times, they seemed incompatible. A valuable commentary gave the reasons for this, both psychological and diplomatic. Few men are so misjudged in Great Britain as Buffon. He had an enormous influence on the thought of his time. He was a man of wide scientific attainments and in every way a man of the world. His Discourse on Style, delivered on his admittance to the Academy of Sciences in August 1753, has given him his place in literature. This celebrated discourse was read at the meeting by M. Toni Taffin of the Comédie-Française. The audience was obviously thrilled to hear the sonorous phrases which probably all had read—there were at least sixty editions of it in the nineteenth century.

Dr. J. Ramsbottom followed with an account of the lives and work of Jean Lamarck and Charles Darwin. Lamarck first postulated progressive evolution; Darwin put the doctrine of evolution on so sound a basis that it became generally accepted. It was a pleasing acknowledgment of Darwin's epoch-making "Origin of Species" that he should be given a prominent place in what was essentially a celebration of French achievements; moreover, it was logical in realizing that it was the book and not the preliminary announcement of natural selection which was important. So Lamarck and Darwin could be spoken of as searchers after truth without some of the nonsense which has been allowed to belittle the former. Comparing the basic ideas of the two—Lamarck held that an organism in a changing environment is stimulated to vary; Darwin that variation is independent of the environment. For both the environment—adaphic, physical and biotic factors, the last including competition, parasitism, etc.—is all-important. Natural selection is not active like artificial selection, but passive: an organism can live under certain conditions, or it cannot. Lamarck suggested that the simpler animals and plants would provide instructive facts. Evidence accumulated since the introduction of pure culture methods suggests that environmental conditions can produce definite inheritable changes, though not necessarily of the kind Lamarck propounded. The boosting up of penicillin production in *Penicillium chrysogenum* has much in common with what Darwin considered to be the effects of domestication.

Mme. G. Duprat, librarian to the Museum, then gave an account of the career of P. J. Redouté, born in 1759, who was artist to the Garden and painted many of the famous *vélins*. She showed a series of projections of portraits of Redouté and a large number of his paintings, several of which were of specimens from the Royal Botanic Garden at Kew. An exhibition was arranged in the corridor adjoining the amphitheatre showing many of Redouté's original paintings and a number of his published plates; also an announcement of his lectures. The Muséum d'Histoire Naturelle, as one of its main functions, acts as a teaching university. There are at present 24 professors who give courses of lectures covering a very wide field, but there are no degrees awarded as the result of examinations. The system is *sui generis*.

Prof. H. V. Vallois, director of the Musée de l'Homme—attached to the Natural History Museum—gave a history of the Société d'Anthropologie, founded in 1857. In spite of the date the Society's beginning was in no way connected with the publication of the "Origin of Species"; indeed, it preceded it by six months. Social and physical anthropology in the widest sense have been the scope of the Society, and its activities, as outlined, make an impressive history. It is noteworthy how Darwin's name became increasingly prominent after the publication of his "Descent of Man" in 1871. Cuvier, the great exponent of catastrophism, died in 1832, but though there was no successor to stamp out heresies his influence was such that Lamarck's beliefs were still discredited and it was not until Darwin amassed and arranged the evidence that inquiries about the status of fossil man became scientifically respectable.

The last paper, by M. Franck Bourdier, assistant chief of the Service de Muséologie, dealt with the French forerunners of evolution. They make an imposing list far outnumbering the combined total from all other countries. The notion of permanent change in organisms and that of evolutionary sequence stood out clearly. It would be useful to distinguish between them, possibly by speaking of the first as transformism and the second as evolution.

In an adjoining corridor an exhibit was arranged where the matter of this lecture could be studied at leisure and in greater detail. Here again Darwin was included as the end of the old period or as the beginning of the new.

In addition to this intellectual feast and as part of the anniversaries, an excellent exhibition was staged in the gallery of the Botanical Museum, dealing with the history of the doctrine of evolution and illustrating development up to and including man. Specimens, casts, models, photographs and all the modern methods of display provided a most instructive and convincing story.

J. Ramsbottom

X-RAY MICROSCOPY AND X-RAY MICROANALYSIS

THE second International Symposium on X-ray Microscopy and X-ray Microanalysis was an independent meeting held in Stockholm in 1959, and sponsored by the same three laboratories as were responsible for arranging the first Symposium, held in Cambridge in 1956: the Department of Medical Physics, Karolinska Institutet, Stockholm; the Departments of Physics and Biophysics, Stanford University, California; and the Electron Microscope Section of the Cavendish Laboratory, Cambridge. The attendance of 180 was 50 per cent greater than that at the previous meeting, although the number of papers presented (74) was not appreciably greater than before (66). The participants were drawn from seventeen different countries and from 120 different laboratories.

The programme was divided according to the nature of the physical techniques employed. X-ray absorption microradiography, X-ray emission microanalysis, and X-ray microdiffraction analysis Each division was sub-divided into sections on methodological aspects and equipment, technical applications and biological applications The number of communications under these three cross-divisions was 43, 10 and 21, respectively, showing that the development of techniques is still enjoying most attention and that their application in biology and medicine is ahead of that in mineralogy and metallurgy

In absorption microradiography, interest was mainly in the relative merits of the contact and projection techniques, only two contributions being concerned with the reflexion method, in which the correction of aberrations is still the main problem For qualitative microscopy, all three methods at present have about the same limit of resolving power, at about 0 25μ H H Pattee (Stanford University) has investigated a number of alternatives to the photographic emulsion for recording the X-ray image in contact microradiography, including radiosensitive dyes and plastics, some of which give images which can be enlarged in the electron microscope J H Auld and J F McNeil (Aeronautical Research and Defence Standards Laboratories, Australia) showed that xerography with liquid developers allows a resolution comparable with that given by ultra-fine grained X-ray films and at exposure times similar to those of the fastest X-ray films In the projection method, improvements are being made in the technique of focusing at very high resolution (W C Nixon, Cavendish Laboratory) and in obtaining improved contrast (S P Ong and J B Le Poole, Delft) The main emphasis, however, was on the perfection of the absorption procedure for microanalysis, whether of particular elements (sulphur, phosphorus, calcium) or simply of the dry weight of biological tissues The contact method has been developed for this purpose, especially in Swedish laboratories, and improvements in the technique were described by Howling and Fitzgerald (New York), Hydén and Larsson (Gothenburg), Lindstrom and Hoh (Stockholm) and Muller and Sandritter (Frankfurt-on-Main) The accuracy of analysis varies between 5 and 10 per cent, depending on the nature of the specimen A detailed study of all the factors involved is being made by Henke (Pomona College, California), using red blood-cells as standard specimen In the projection method direct measurements can be made with a counter on the enlarged X-ray image, thus eliminating the stages of photography and microphotometry, so that the accuracy of analysis is better In determinations of calcium in bone, Long (Cavendish Laboratory, Cambridge) obtained 2–3 per cent accuracy The smallest area which can be analysed is a few microns in diameter in either method, the limit being set by the light spot in microphotometry and by the counter aperture in projection recording The ultimate mass sensitivity is of order 10^{-11}–10^{-12} gm , since sections thinner than 10μ cannot be used

The applications of absorption microradiography, by one or the other experimental technique, covered a wide range of subjects In the inorganic sciences, papers were concerned with mineral dressing, petrography and mineralogy , in biology and medicine, with bone (six papers), vascular systems (five papers), other animal tissues (four papers, including a wide survey by Saunders, of Dalhousie University), plant tissues (two papers) and foraminifera (one paper) Most of this work was qualitative, only Lindstrom (Stockholm) and Sissons (Institute of Orthopædics, London) describing quantitative applications

X-ray emission microanalysis is more definitely a quantitative method, and rapid progress is being made with its development now that its value in metallurgy and mineralogy has been demonstrated In biological research, where compounds rather than elements are of interest, its scope is much more restricted The mechanism of emission is more complicated than that of absorption and in practice results are subject to a variety of corrections The efficiency of X-ray production by direct electron excitation was discussed by Archard (Associated Electrical Industries Research Laboratory, Aldermaston) and by Cosslett (Cavendish Laboratory, Cambridge), and the corrections for absorption and fluorescence by Philibert (Institut de Recherches de la Sidérurgie, Paris) and by Austin, Richard and Schwartz (Battelle Institute, Columbus) The factors limiting the spatial resolution (or 'localization') of the method were discussed by Duncumb (Cavendish Laboratory, Cambridge), the main factor being the very rapid decrease in electron-beam current as the focal spot is reduced to less than 1μ in diameter At present the practical limit is about 0 25μ, and further improvement must wait upon developments of the electron source, electron lenses and recording system A great gain is attainable if a proportional counter can be used for wave-length discrimination, instead of a crystal spectrometer, and Dolby and Cosslett reported promising results with a counter of wide collection angle coupled to an electrical network which can separate the pulses produced by neighbouring elements in the periodic table

Improvements in the design of microanalysers were reported from the laboratories of Associated Electrical Industries (Aldermaston) and Tube Investments (Hinxton) and from the Cavendish Laboratory The Associated Electrical Industries instrument is now being manufactured by Metropolitan-Vickers and the first model was on view during the meeting The production of the scanning microanalyser developed in the Cavendish and Tube Investments laboratories, which displays images of the distribution of selected elements in the specimen, was announced by the Cambridge Instrument Company The original static spot instrument of Castaing is in production in France, and two similar instruments are now being commercially made in the United States This activity has been stimulated by the great interest now shown in the method by metallurgists and mineralogists, which was reflected in the papers on applications by Austin, Long, Melford (Tube Investments) and Philibert All elements with atomic number greater than 11 (sodium) can already be analysed, with an accuracy in favourable cases of better than 0 1 per cent Since the localization of the analysis can be smaller than 1μ, in depth as well as in diameter, this corresponds to a minimum detectable mass of about 10^{-14} gm As the range of applications is extended, however, it is becoming clear that the limits of accuracy must be more closely investigated in each special type of alloy or mineral The work of Philibert on light alloys showed that very careful correction needs to be made for fluorescence effects as well as for absorption of X-rays from one constituent by the others present To reduce such corrections to a minimum, it will be desirable to build up a collection of reference standards so that one may be selected which is as close as possible in composition to the specimen under investigation. Comparison of the results obtained in three different laboratories, on the variation of nickel content across tænite inclusions in the same type of meteorite, indicated that standard methods of preparing the specimen must also be worked out. It was unfortunate that only an extended abstract was available of what would have been a most interesting paper by Borovski (Institute of Metallurgy, Moscow), who has independently developed the X-ray micro-analyser for metallurgical research. It appears that he has made great progress not only with standardizing the procedures, but also in the automatic recording of concentration curves. His main interest is in diffusion problems and in transfer processes between solid and liquid media.

In summary, it can be said that the emission microanalyser is leaving the stage of being an interesting piece of gadgetry and is now having to prove itself as a routine research tool, in the course of which its capabilities and limitations will become more clearly defined. In particular, it remains to be seen how far it can help in some of the main problems of ferrous metallurgy: exploratory determinations of carbon have already been made by Dolby, but what the limits of accuracy may be and whether carbon and nitrogen can be distinguished from each other are problems still to be solved.

The Symposium ended with two sessions on micro-diffraction, which becomes increasingly related technically to X-ray microscopical methods as the advantages of using micro-focus tubes are more widely appreciated. Further developments were described in the tubes themselves and in the spectrometers and micro-beam cameras used with them. The value of the method, especially in reducing exposure time to more practical limits when only very small crystals are available, emerged strongly from the work of Fournier (Centre National pour la Recherche Scientifique, Paris) on crystals from tumours, Mrs. Kennard (National Institute for Medical Research, London) on a number of clinical problems, Skertchly (Textile Physics Laboratory, Leeds) on keratinization of hair, and Wylie (Royal College of Technology, Glasgow) on the growth of crystals in balsa wood. Quite different techniques have been developed for investigating dislocations and other sub-structures in metals, by combining Bragg diffraction with X-ray microscopy. Extensions and applications of this 'Berg–Barrett' method were described by Newkirk (General Electric Laboratories, Schenectady) and Weissmann (Rutgers University, New Jersey). Shinoda and colleagues (Osaka University) had used a transmission variant of the method to investigate the recrystallization of zirconium and its alloys on the micro-scale.

A third symposium is planned for 1962, and will probably be held at Stanford University, California.

V. E. COSSLETT

THE BRITISH GELATINE AND GLUE RESEARCH ASSOCIATION

THE seventeenth meeting of the Research Panel of the British Gelatine and Glue Research Association was held on June 25, with Mr. S. G. Hudson (Richard Hodgson and Sons, Ltd.) in the chair. In the morning a review of certain aspects of the research of the Association was given by Mr. A. G. Ward, for whom it was the last meeting as director of research, and in the afternoon a discussion on gelation took place, with the main contribution from Mr. J. W. Janus (Kodak, Ltd.).

The review by Mr. Ward was entitled "The Present Position in Gelatine and Glue Research". The paper opened with a reference to a previous review given by the author to the second Research Panel meeting nine years earlier, in which considerable attention was given to those methods of polymer physics and chemistry which were applicable to the study of gelatin. The expansion of research on gelatin now made it necessary to limit the paper to the central problem of the structure of the molecules of the many different types of gelatin. This largely left on one side research on the collagen–gelatin conversion and also on gelation, except where these subjects threw light on the molecular structure of gelatin.

The chemical composition of gelatine, and animal glue, were shown to depend on the amino-acid composition of the gelatin itself, that is to say, of the collagen breakdown products, and on the occurrence and composition of rather small amounts of non-gelatin constituents. Separation procedures such as adsorption on activated charcoal, or '*IRC*50' resin, enabled small quantities of gelatin-free impurities to be obtained and analysed, and examination of fractions prepared with *iso*propyl alcohol showed that about 1 per cent of degraded protein, other than gelatin, might also be present in the residue from fractionation. Using hydroxyproline content as a measure of purity, it was suggested that a total of 3 per cent of organic impurities might be present, although the variation in hydroxyproline content could equally be the result of small differences in composition between gelatin molecules.

Revision of figures for the amide content of gelatines enabled very good agreement to be obtained between the analytical figures for the ionizable groups in gelatin and the results of titration curve determinations. This shows that, within experimental error, all the carboxyl, amino and guanidino groups are free to ionize and are not cross-linked. The accuracy attained did not make it possible to exclude the occurrence of a small number of cross-links involving these groups.

The properties of preparations of well-characterized soluble collagen extracted from calfskin, carp-swim bladder tunic and codskin, by Doty and co-workers, and their conversion of the soluble collagens to gelatin, could be explained in terms of dissociation of the triple-helix collagen structure. The gelatins obtained would, on this view, be single chains, free of cross-links. In contrast, first extract alkali process gelatins have been shown by Courts and Stainsby, using end-groups and light-scattering determinations of molecular weight, to be multichain, at least for the higher molecular weights. The relation between these results was discussed.

The problem of explaining the reduction in gel-forming ability in gelatine caused by neutral and alkaline degradation, although not by acid degradation, as distinct from any effect due to the reduction in molecular weight, still remained to be solved Suggested explanations were put forward in terms of internal re-arrangements of the protein chains which upset the ordered arrangement required for a gel bond, or alternatively, that intra-molecular cross-linking occurs progressively on heating under neutral or alkaline conditions, and interferes with subsequent gel formation

After a brief discussion Dr A Courts (British Gelatine and Glue Research Association) in moving a vote of thanks, expressed the appreciation of the staff of the help given to them by Mr Ward in his term of office Mr C F C Simeons (British Gelatine Works, Ltd), in seconding, added the thanks of the gelatine and glue industry

Mr Janus, in opening the discussion on gelation, gave a short paper on "The Formation and Structure of Gelatin Gels" He described the measured properties of gels, the rigidity of the matured gel, the melting-point and the setting time from the sol state, and showed how these depended on solution *p*H He emphasized that setting might occur in a short time even at room temperature, whereas the gel rigidity increased over long periods at 0° C The melting-point was, however, much less influenced by low-temperature maturing

The influence of guanidino content on setting time and melting-point was made clear, but not that on low-temperature rigidity Interference with setting can also be secured by alkaline copper solutions which are presumed to interact with the $\rangle$CO groups of the backbone An interaction between guanidinium groups and the backbone was therefore postulated as the mechanism of the early stage of setting To explain the continued growth of rigidity at low temperatures, reversion to the helical structure was suggested, and support was drawn from the optical rotation changes

Dr R Collison (British Baking Industries Research Association) presented a short paper by Dr G A H Elton and himself on "The Swelling of Starch" In this he described the swelling of the granules in water as the temperature is raised, and effects on the mechanical properties He also mentioned the action of surface active agents in controlling swelling, probably by forming a hydrophobic layer on the granules

Mr D D Carruthers (University of Durham) described measurements on gelatin gels at high frequency, and discussed the dependence on temperature of the mechanical properties

The general discussion was opened by Dr G Stainsby (British Gelatine and Glue Research Association), who emphasized the difficulty of establishing precisely the mechanism of gelation The vote of thanks to Mr Janus and the other speakers was moved by Mr E Bradbury (British Cotton Industry Research Association) and seconded by Dr A Jobling (British Glues and Chemicals, Ltd)

ALAN G WARD

THE TORRY RESEARCH STATION, ABERDEEN

THE Torry Research Station in Aberdeen of the Department of Scientific and Industrial Research, which was set up in 1929, together with its sub-station in Hull, the Humber Laboratory (opened in 1952), carries out research into the problems of fish preservation The occasion of the open days during June 15–17, when the Station was on show to scientists, equipment manufacturers, the fish industry and the general public, provided an opportunity both of seeing the range of practically the whole of the research in the United Kingdom into fish technology and also of assessing how the treatment of the fish we eat is likely to change in years to come

Although the fish industry has changed in numerous ways in the thirty years since Torry was opened, it nevertheless remains largely 'traditional', there are many small firms, mechanization to any substantial degree is found only in a few factories and, with the exception of deep freezing, the methods of preservation used were familiar to our grandparents Torry, which has been closely concerned in many of the changes which have occurred, is becoming more and more closely occupied with the technical development of the industry of the future Changes are occurring at an increasing tempo and the next decade is likely to see a much greater alteration in both techniques and organization than the previous 30 years have done

One of the major problems concerning our supply of white fish is that about half of it comes from Arctic waters The fishing grounds are anything from three days to one week's steaming from the Humber ports, on which almost all the long-distance trawlers are based, and this consequently sets a limit to the age of the freshest fish that can be landed Voyages are on an average of nearly three weeks duration and the fish caught first may therefore be 16–17 days old when it is landed Cod and haddock, even when properly stored in crushed ice, remain in reasonably good edible condition for only 14–15 days About ½ per cent per annum of the Arctic catch is in fact condemned at landing as unfit for human consumption After landing, the vicissitudes of the distribution chain may render passable fish unpleasant and good fish only passable

Since the Second World War, considerable attention has been paid at Torry to the problem of how to get fresher fish to the consumer A promising solution is to build a trawler capable of freezing the first third of the catch That the idea is practicable was shown in a full-scale trial carried out in 1955–56 under Torry's technical supervision and financed jointly by the Distant Water Vessel Owners' Development Committee, the White Fish Authority and H M Government A Grimsby trawler was fitted with vertical plate freezers developed at Torry and capable of operating satisfactorily in the exacting conditions of Arctic fishing, and with a − 30° C cold store The frozen fish was distributed to consumers throughout the country whose reactions were almost universally favourable The latest development is the design of a vessel of normal size and cost which would show attractive economic advantages over existing high-speed trawlers Such a vessel would be a trifle slower than the latter, the extra 1–2 knots of which are disproportionately expensive to obtain It could spend rather longer on the fishing grounds and therefore land a greater weight of fish The frozen part of the catch could be used to even out the supply from the summer glut to winter dearth

Another possible way of slowing down the rate of spoilage of fish is to use antibiotics such as chlortetracycline and oxytetracycline Much of the pioneer work has been carried out in Canada, where their use is now permitted, but they may not yet be used in the United Kingdom One of the major tasks in hand is to determine the quantities of these substances likely to get into and remain in the flesh after various types of storage, processing and cooking Even those antibiotics most effective in fish preservation have limitations ; there is little difference in the flavour of fish stored in plain water ice and in antibiotic ice up to about the tenth day, so that no more could be done than to keep fish that would otherwise become poor or very poor in a passable, but not really fresh, state

A recent survey carried out by staff of the Humber Laboratory and workers seconded by the White Fish Authority of the temperatures of fish during distribution from unloading from the trawler to sale from the fishmonger's slab has stimulated considerable interest within the trade and is already bringing about improvements in practice It represents another approach to the same problem of how the quality of fish reaching the consumer can be raised This survey is probably the first large-scale attempt in any country to obtain first-hand field data of this kind It is typical of much of the work carried out at Torry, since it was made possible only by the co-operation of the industry and was initiated by discussion with representatives of the fish trade

The Station necessarily supplements such practical applied investigations and development work with a considerable volume of basic research Thus, a greater understanding is being sought of the detailed structure and composition of fish tissues, and of their behaviour during processing such as freezing and cold storage, smoking and drying Knowledge is also being acquired of the composition of the bacterial flora of fish and the nature of the species mainly responsible for spoilage Studies since the War have contributed to improvements in the taxonomy of the marine bacteria mainly concerned and in the building up of a type culture collection now of international reputation

Solid progress in recent years in the characterization and estimation of the so-called 'extractives' of fish muscle is providing a clearer insight into the autolytic changes that take place immediately after death and during bacterial spoilage This work is of particular importance in understanding the various physico-chemical changes that occur during dehydration, freezing and subsequent storage of fish, as well as the factors which give rise to different types of spoilage flora under various conditions Recent years have also seen the accumulation of new knowledge of the main proteins of fish muscle which is serving in particular to explain the causes of textural change during freezing, cold storage and dehydration Mention should be made of the work on the Maillard 'browning' reactions which occur in dehydrated fish muscle

Considerable attention has been given to the prevention of oxidative rancidity in cold-stored fatty fish Fish fats are highly unsaturated, and frozen fatty fish such as herring remain in really edible condition for a shorter period than white fish The rate of oxidation of fish fat can be slowed down by 'glazing' ; this consists of dipping the frozen fish in water so that a layer of ice is formed around the outside Drying of fish in cold store hastens the development of rancidity , even more important, therefore, is to store fatty fish under conditions where drying is at a minimum Current work on the oxidation process may eventually lead to economic improvements It has been found that fat oxidation is catalysed by hæmatin pigments in the red lateral muscle which is present in a well-defined form only in fatty fish

Nevertheless, there are limits to the cold-storage period even of species like cod which contain considerably less than 1 per cent fat in the muscle , the fat becomes oxidized and there are progressive changes in the protein structure common to all fish Recently, a new method has been devised for assessing the development of toughness in cold-stored fish This depends upon the fact that although fresh unfrozen muscle can be macerated in dilute formalin solution to give a thick opaque suspension, there is a tendency for the fibres of frozen fish to resist maceration and this resistance increases as a function both of storage time and of storage temperature By determining the amount of light transmitted by the 'soup' of fish fibres produced under standard conditions it has been found possible to relate samples to a standard time/temperature curve This test, the validity of which requires further checking to cover a number of variables, is so simple that it could easily be adopted by the fish-freezing firms which, with one or two notable exceptions, do not employ scientifically trained staff and do not possess quality control or development laboratories

Fish freezes more rapidly than it thaws, due to the difference of thermal conductivity through frozen and unfrozen tissue For example, a block of fillets 4 in thick may freeze in 4 hr or so but may take 20 hr to thaw out in air at ambient temperatures A number of firms use large quantities of frozen fish for their products , for example, there is a variety of ready-cooked fish products prepared initially from frozen fish and sold in frozen consumer packs, and the kippering industry uses large amounts of frozen herring when fresh herring is not available At present, fish is thawed on a large scale, either by merely leaving the frozen blocks in air or by spraying with cold water The latter method, if it is carelessly carried out, may adversely affect the quality of the product, and both methods are time- and labour-consuming Attempts by workers in other countries to apply dielectric heating have not been successful, mainly due to 'runaway' heating This is the condition in which there is progressively increasing absorption of the available power in warm spots in the blocks, which become cooked , this is at the expense of the cooler portions, which remain frozen Recently this difficulty has been overcome and commercially available equipment has been slightly modified , a pilot plant has been running at Torry without trouble for the past six months or so Blocks of frozen fish can be evenly thawed in about 15 min The technological implications of this work are very wide indeed

The commercial smoking of fish is still largely carried out in the traditional smoking kiln which was developed during the early Middle Ages This is merely a chimney in which brined fish is hung and a sawdust and wood-chip fire lighted on the floor The operation takes anything up to 12 hr or more to complete The irregularity of natural convection, and the effect of warm humid weather on the functioning of the kiln, render fish-smoking an art which is difficult to practise In 1939 a mechanical kiln was developed at Torry which simplified the process and made it much easier to control Although the industry was at first slow to adopt the new kilns, an increasing number of firms are now doing so Intriguing possibilities are, however, now being suggested as a result of basic physical and chemical work on the composition of wood smoke It has been shown that virtually all the smoke constituents on smoked fish are derived from the invisible vapour phase and not the visible particulate phase The practicability of smoking fish with 'smokeless' smoke and further developments as well are envisaged

There is a continuous programme of work at Torry on the improvement of the efficiency of conventional fish-meal plant Emphasis is put upon methods of increasing production, plant efficiency and nutritive value of the product

It is important to stress that the high standing of the Torry Research Station within the fish industry itself is very largely due to the considerable amount of consultation and discussion which takes place with the industry and, not less important, the very good relationship built up between individual scientists and various people 'in the trade' Much of the development and survey work carried out within the past ten years would have been quite impossible without the close and friendly co-operation of the industry, on this personal contact between government research workers and the industry the future development of this relatively undeveloped and traditional industry, without any research organization of its own, depends

G H O Burgess

FISHERY RESEARCH

Dr BREDER has prepared a valuable review of work on social grouping in fish*, it also contains new data, though it is sometimes a little difficult to pick these out He discusses in detail the various types of groups the aggregation, where the individuals are not 'polarized', the school, where they are, and the pod, where the fish are in physical contact These types of groups are illustrated by outstandingly good photographs, those of pods and fish in 'orderly files' being the most interesting

Descriptions of new work are mainly of the effect of light intensity and colour on a number of species and the analysis of the internal structure of schools In the experiments on the effect of the wave-length of light the fish were given a choice between different colours, the intensity of the different colours being equated photometrically No attempt was made, by determining the spectral sensitivity of the fish, to equate the subjective intensity, or intensity as it appeared to the fish Of particular interest are Dr Breder's discussions on the leadership of schools, the school as a super-organism and the evolution of schooling behaviour There is also a section on schooling in terms of cybernetics, where the point is made that the survival of a species which has grouping tendencies should perhaps be considered from the point of view of how they have got over the danger involved, rather than that such tendencies automatically have survival value

Dr Loukashkin's and Dr Grant's work on *Sardinops caerulea**, a species of great commercial importance, has much in common with Dr Breder's but is more limited in extent It is again well illustrated with photographs Like other clupeoids, *Sardinops* is not an easy subject for experiment, but results have been obtained which show the importance of light for the maintenance of school formation and that fright reactions are elicited by red lights and by flashing white lights When given the choice between red, green, blue and white light, the fish avoided red and preferred blue and green to white As in Dr Breder's work, this technique has a limitation in that the intensities of the different colours were not equated subjectively but only photometrically

This type of behaviour work, which may be considered important as an aspect of fisheries research, is now being produced in much greater quantity than before the War, and it is particularly welcome to the fisheries research worker when it is concerned with species of commercial importance

THE ONTARIO RESEARCH FOUNDATION

THE annual report of the Ontario Research Foundation for 1958 (pp 36 Toronto Ontario Research Foundation, 1959) includes, besides the report of the director, Dr H B Speakman, a summary of the work of the various sections, a list of papers published during the year, the financial statement and details of the Board of Governors and professional and technical staff There is also a list of grants for postgraduate studies in science for the period 1958–59, for which grants in 1958 totalled 145,204 dollars In biochemistry three major projects, dealing with the development of an all-temperature biscuit spread for the Defence Research Medical Laboratories, tea, and the recovery of pure individual amino-acids from wheat gluten after hydrolysis, were completed, and two major studies are in progress under the Rice Mills Fellowship In chemistry, activity was maintained at a high level The three-year survey of air pollution of the Hamilton area was completed, while the development of gas chromatography proceeds apace In a study of factors controlling the crystallinity of polymers, techniques developed for preparing polymers of butane with 50 per cent of crystallinity are being used to study the relation between the type of catalyst and polymer structure A novel ion-exchange process for recovering ammonia from ammonia-base waste sulphite-liquor has been developed and a pilot plant constructed A comprehensive study has been continued of various sulphite-liquors and their fractions and has led to a patent application , there have been utilization studies on by-product lignin from the manufacture of vanillin, while research on phosphate glasses has been continued in the Na_2O—P_2O_5—H_2O system centred largely on the constitution of sodium acid glasses of intermediate composition, using filter paper chromatography

In engineering and metallurgy basic research was directed at the concentration of hæmatite by a combination of magnetic and mechanical methods or by roasting methods followed by magnetic separation In work on dry magnetic separators the 'Fast Eccentric Drum Separator' has been developed to the point of commercial production In basic research on the fatigue of metals three stages have been distinguished (*a*) the first four thousand cycles , (*b*) a slow steady decline in cyclograph (magnetic test) , and (*c*) the last 15,000–20,000 cycles in which the final crack is developing A precision camera was designed and built for stress determination in X-ray work

In the Department of Parasitology most of the work was a continuation of earlier projects, and persistent effort has provided an understanding of the prevalence and mode of transmission of some of the many parasites of Ontario's wild animals Similar studies on wild birds are in progress, and during 1958 the blood parasite of ducks, *Leucocytozoon simondi*, was successfully grown on tissue culture in test-tubes Continued studies of two types of blood parasites of birds have shown that certain types of black flies transmit them to ducks, while others transmit them to ruffed grouse In physics some fundamental work dealing with beams of electrons has been planned, while other projects included development of an atmospheric X-ray spectrometer, design procedures for dynamic pressure stages, determination of gas density by electron beams and high-energy applications of electron beams The Department of Physiography completed an extensive study of the fine sand fraction of representative soils and a five-year environmental study of soya bean is nearing completion Research on the chemical modification of wool continued in the Department of Textiles as well as a study of the colour fastness of spun-dyed viscose yarn Good progress is reported in the standardization of women's and children's garment sizes for the Canadian Government Specifications Board

INSTRUCTIONAL FILM RESEARCH IN PENNSYLVANIA

THE Pennsylvania Instructional Film Research Program was established in 1947 and terminated in 1955 Jointly sponsored by the U S Army and Navy, it represents the largest piece of co-ordinated research yet carried out on the teaching film Accounts of the early part of the research have appeared in *Nature*[1] It is the purpose of this article to complete the outline record by reviewing the last reports—now gathered into one volume[2]

The later work follows directly on the earlier, confirming it, filling in details and dealing with specific problems But some new and interesting notions of a general sort arise in this process The very last studies, 100–104, deal with training aids such as models and other apparatus that are not films Two of the studies, 46 and 50, are related to the use of films in psychotherapy These two studies, as well as study 60, are concerned with films which influence attitude The main classes of films dealt with in the research have been those which impart information and those which teach perceptual-motor skills

A number of the studies yield information of general practical use For example, study 37 by Philip Ash and Nathan Jaspen—see report *SDC* 269–7–37—examines optimum viewing conditions Using a small rear projection daylight screen in teaching a performance skill—the assembly of a gun breech block—the optimum viewing area was found to be a sector 60° wide and 12 screen-widths deep Increasing distance from the screen beyond 12 screen widths led to much sharper loss of teaching effectiveness than increasing angle of view beyond that of the 60° boundary Outside the optimum viewing area loss was greater under daylight than under dark viewing conditions These results may be compared with those found for a standard size screen and projector by J J Gibson[3] he found that within a sector up to 90° wide and 7 screen-widths deep there was no loss in teaching effectiveness

The Pennsylvania film research organization has always stressed that teaching films should be tested "with adequate samples of appropriate target audiences using reliable and valid tests", rather than by viewing panels Nevertheless, assessing teaching effectiveness by a viewing panel remains often the only practical alternative Study 57 by L P Greenhill investigates such assessing, and recommends a particular type of film analysis form (or questionnaire) , this panel testing procedure being used to select the best of several films, or to improve the teaching effectiveness of a film still under production Study 59 by A L Edwards provides a statistical methodology which might be used when assessing films by the panel method The report on study 48 about making simple demonstration films with untrained personnel includes—as an appendix—a 'manual for minimum film production'

Infra-red photography offers an excellent means of recording audience reactions—of children and others —under conditions of little or no visibility But infra-red motion photography is expensive Study 56, by L P Greenhill, investigates the less costly use of infra-red memo-motion photography This is essentially time-lapse photography The photographs were taken on 16-mm infra-red film at the rate of one a second, a rate which appears sufficiently frequent to show most types of human activity The record was synchronized with the events on the screen, by the synchronous drive of camera and projector, and more satisfactorily by the use of a mirror reflecting a small image of the screen into the camera—so as to appear at one corner of each memo record frame

In one of the earlier Pennsylvania studies[4] it was found that a rating profile for a film, showing peaks for an audience reaction of 'I am learning' and valleys for a reaction 'I am not learning', provided a valid index of learning. The subjectively based graph was found to be highly correlated with one based on the results of an objective learning test. This finding—although it has yet to be fully established—has considerable importance in connexion with film research, because it justifies a simple procedure in place of the present elaborate one of objective testing. In some measure it is further confirmed by study 55. In this study, by Richard M. Fletcher, it was found that a team of competent assessors could shorten film commentaries without reducing teaching effectiveness considerably more when aided by a learning profile than when not so aided—in one case 26 as against 11 per cent. However, Richard M. Fletcher says that the results of this study should be interpreted carefully. In an interesting discussion of results he considers the implications of the reactions 'I am learning' and 'I am not learning'.

The notion of 'realism' as a factor influencing the teaching effectiveness of films has received attention in early Pennsylvania studies, in relation to viewing angle[5], stereoscopy[6] and colour[7]. It emerges as a more conscious notion in the later work. In study 49 on the validity of pictorial tests and study 47 on the use of films in a Thematic Apperception Test, 'iconicity' is considered. This term derives from C. Morris's work. "A sign is iconic to the extent to which it itself has the properties of its denotata[8]." The study of the features and combinations of features that lead to life-likeness in films has been called by the present reviewer 'simulacrics'[9]. In listing eight hypotheses of film research it is possibly significant that the director of the Pennsylvania research should have given the sign similarity hypothesis first: "That films whose signals, signs, and symbols have high degrees of similarity ('iconicity') to the objects and situations which they represent will be more effective for most instructional purposes than films whose signals, signs, and symbols have low degrees of 'iconicity'[10]."

Report 40 provides a valuable bibliography of production, utilization and research on instructional films. It contains about 600 references dating up to the early part of 1952, arranged alphabetically by author.

One or two of the early Pennsylvania studies have been criticized on the grounds that they are directed towards findings that are obvious in the first place. Perhaps more justifiably one or two other of the Pennsylvania studies have been criticized because they have been concerned with teaching in general rather than teaching with films in particular. The Pennsylvania research includes relatively little basic research on the film medium itself. In general the method has been to carry out experiments using the prevailing current picture-cum-commentary type of instructional film, and consequently to improve that type.

But such comment on isolated studies and minor aspects of the Pennsylvania research seems almost out of place in view of the enlightened way it has been directed and all it has accomplished. In 1947 there was no body of experimentally attested principles about teaching films and no proved techniques of film research, which thanks to the Pennsylvania work exist now. This work—which might so easily have been restricted to fulfilling limited training needs—has yielded results of value to teachers generally and to psychologists. Credit is due to the associate directors C. R. Carpenter and L. P. Greenhill, who with some of their staff now form an organization at Pennsylvania State University that has already investigated the use of closed-circuit television in university teaching.

BLOOD GROUPING OF THE REMAINS OF SWEDENBORG

By MADELEINE SMITH

Anthropology Section, British Museum (Natural History), London, S.W.7

EMANUEL SWEDENBORG was born on January 29, 1688, and died in London on March 29, 1772. He was interred in the vault of the Swedish church in London. His remains were disturbed on several occasions; an account of these was given by Hultkrantz[1]. The coffin was first opened in 1790, and there is little doubt that this unauthorized action made the removal of the skull possible. The vault was opened at least nine times between this date and 1816. It has been suggested that a skull was stolen from the coffin on two occasions between 1816 and 1817. In consideration of the vogue enjoyed by phrenology at this time, this is not a remarkable fact. On the first occasion the instigator was probably the famous phrenologist Captain Holm, whose collection already included the skulls of Alexander Pope and Casimir Périer. The presence of a Swedenborg skull in his collection was disclosed to his niece in 1845, but regarded as a family secret. There is some evidence that Holm introduced a substitute into the coffin. In a letter to *The Times* of April 4, 1823, Hawkins states that the skull was removed in 1817, by Captain Granholm, a Swedish sailor, for financial gain. On his death this skull passed into the possession of Wahlin, pastor of the Swedish church in London. A skull claimed to be that of Swedenborg was in the collection of Charles Tulk, M.P., in the years prior to 1823, and it is thought possible that Wahlin gave it to him for safe keeping Tulk had casts made of this skull just before it was replaced in the coffin on March 25, 1823, in the presence of Wahlin This is the skull now present in the coffin There is no conclusive evidence as to its authenticity in the documents available In 1908 a letter was received at the Swedish Legation in London, from an individual claiming to have seen Swedenborg's skull in the collection of an antiquary in the 1870's It would seem probable that this is the skull from Holm's collection, but the evidence obtained to date is not conclusive This skull was traced, and is now in the possession of Dr Charlotte Brandt Distinction between the two skulls would appear to be possible only by means of objective scientific tests These have now been undertaken by Prof Folke Henschen and his colleagues in Stockholm, and at his request blood group analysis has been carried out at the British Museum (Natural History)

The material available from Uppsala consisted of portions of the parietal and mastoid bones of the skull (treated as one specimen in the blood grouping tests), a metacarpal bone, part of the right femur, fragments of a cervical vertebra and soft tissue from two regions of the right arm The last two samples included portions of cloth The English' skull, which has been described elsewhere[2], was entrusted to us by the present owner, Dr Charlotte Brandt Measurements of this skull are available in the records of the British Museum (Natural History) and a full description will be published with the complete account of studies on the remains of Swedenborg in the *Acta Regiae Societatis Scientiarum Upsaliensis* From this skull a section of the left parietal bone was cut out with a high-speed circular slitting saw, and diploic tissue removed with a dental drill This method has allowed replacement of the section without visible evidence of the action of the saw or drill The removal of sufficient material for testing would not have been possible from a skull by other methods without visible damage Bone from the skeleton was also prepared by drilling or by pulverizing in a mortar The flesh samples were separated as nearly as possible from the accompanying cloth with forceps

The technique of blood grouping employed is essentially similar to that discussed by Boyd and Boyd[3] and modified by Candela[4] for application to bone This technique is one in which evidence of the presence of a group specific antigen may be presumed if antiserum of suitable strength is inhibited in its activity with red cells of the appropriate group, after it has been in prolonged contact with the tissue sample Four naturally occurring human anti-A sera and four anti-B sera were used on each specimen, where the quantity of material available permitted this These were diluted to bring the resulting titres of absorbed and unabsorbed sera to a convenient level for titration purposes It was found that for any one serum these titres always fell within a range of three tubes Titrations were carried out with a fresh 2 per cent suspension of A_2 and B cells[5] In all cases these antisera were known to give satisfactory results with control material of known blood group (that is, typed during life)

Candela's technique has been slightly modified, as follows 0 2 gm of prepared tissue was placed in a 75 × 10 mm tube and 0 4 ml antiserum added to each sample After careful mixing the tubes were placed in the refrigerator for 24 hours, and at the end of that time centrifuged at moderate speed for 2–3 min The supernatant was removed to a clean tube, using a Pasteur pipette with a small cotton-wool wad around the tip[6] If bone particles had not been completely removed, the tubes were re-spun Titration was carried out as described by Boorman and Dodd[5] Buffered saline containing 1 per cent sodium azide as proservative was used throughout No result has been accepted as positive unless a consistent inhibition was observed with any one serum over the entire series of tests Results in all cases are based on a series of at least four tests on the same sample, using a technique of replacement of the same antiserum Table 1 shows the inhibition values for the femur from Uppsala, on one anti-A and one anti-B serum from the series It illustrates the standard of inhibition on which the determination of the blood group has been based

Table 1

Test No	Serum					
	Anti-A			Anti-B		
	1 16	1 32	1 64	1 64	1 128	1 256
1	+	–	–	++	+	(+)
Control	+++	++	+	++	+	w
2	+	–	–	++	++	+
Control	++	+	w	++	++	+
3	(+)	–	–	+++	++	w
Control	+++	++	+	+++	++	w
4	++	(+)	–	++	+	vw
Control	++	+	w	++	+	w

In at least one other laboratory anti-A sera are reversed with anti-B sera on each sample (Gray, personal communication) This method could be unreliable because of the presence of alcohol-soluble group substances in all sera[7], and it has not been found to give clear results in this laboratory In using a replacement technique over a series of tests it has been found possible to confirm or reject results which on first testing appear doubtful, and this method is therefore preferred

The Uppsala remains were tested together, but the 'English' skull was not obtained at the same time, and was therefore tested in conjunction with a further sample of the Uppsala skull at a slightly later date All this material had a very fresh appearance, giving a strong smell on drilling The diploic tissue of the 'English' skull, in particular, appeared to contain a large quantity of organic matter, but when allowance had been made for the different environmental conditions in which each had been preserved, no difference of sufficient significance could be observed which would allow of any distinction in the historical age of the two specimens (Table 2) Fluorescence under ultra-violet lamp showed no distinction between the two skulls in comparison with the long bones

Table 2

Nitrogen content of the material

Coffin skull	4 5–4 8 mgm	nitrogen per 100 mgm bone
'English' skull	3 9–4 1 mgm	nitrogen per 100 mgm bone
Coffin femur	4 4– mgm	nitrogen per 100 mgm bone

In discussing the results obtained on these bones, it is relevant first to consider the present-day distribution of the ABO groups in Sweden Jesper Swedberg, father of Emanuel, came from Dalekarlia although his mother was of German origin Figures for this area of Sweden are available from the paper by Beckman[8] (Table 3)

Table 3

	No.	O	A	B	AB	*p*	*q*	*r*	*D*/σ
Beckman (Kopparberg) (conscripts)	7,952	39·94	44·05	11·54	4·46	28·28	8·36	63·36	+ 1·33
London*	37,216	46·43	41·57	9·16	2·85	25·53	6·23	68·27	0·70

* Means of six series quoted in ref. 9 (the small series of Dyke being omitted).

It will be seen from these figures that a high frequency of group A is characteristic of the population. Assuming the possibility that the Uppsala skull, if a substitute, may have been English, we must also consider the distribution of the ABO groups in London (Table 3).

Inhibitions obtained from this material, although not strong, were consistent, with the exception of the flesh samples. In these, while a clear inhibition for group A was obtained, some inconsistent absorption was seen with anti-B sera. Conclusions as to the blood group of the skeleton have been based, therefore, on the results obtained from the femur, the cervical vertebra, and the metacarpal bone. These give inhibition of all anti-A sera, and none with anti-B sera. The Uppsala skull shows the same result. The 'English' skull failed to show any inhibition with any anti-B serum and with one of the four anti-A sera, and had ceased to inhibit the three remaining anti-A sera at the fourth test. In view of the very clear evidence offered with anti-B sera it is felt that the interpretation of these results may be made with confidence, and the presence of group A-specific substances postulated in all the samples. As has already been noted, the distribution of this blood group in the postulated areas of origin of the material made this result probable. It has not proved possible, therefore, to distinguish between the two skulls on the evidence afforded by blood grouping.

In considering the possibility that these results may be due to the presence of contaminants, it must be borne in mind that in consideration of the known history of the bones, it might reasonably be inferred that they had not been buried in soil. The evidence offered by Thieme, Otten and Wheeler[10] on the action on group-specific substances of certain anaerobic saccharolytic bacteria present in soil might therefore be considered irrelevant to the present study. It has been suggested that substances present in the soil, such as the Forssman antigen, may give results ascribable to group A substances[11], but no evidence has been brought forward. Other sources of bacterial activity remain possible, however, and it was thought to be of interest to submit unlabelled samples of both skulls and of the femur from the coffin to Drs. Allison and Perkins, of the National Institute for Medical Research, for the detection of bacterial contamination. Acid hydrolysates of this material were submitted to paper chromatography, for the detection of muramic acid and diaminopimelic acid. These are known to be constituents of bacterial cell-walls, but have not been detected in human tissues. These substances could not be shown to be present in the Swedenborg material. This result excludes gross bacterial contamination, but it remains to be shown whether the presence of bacteria in amounts sufficient to absorb blood group antibodies can be detected by the chromatographic technique. Should this prove to be so, the use of this technique in conjunction with the blood grouping of tissues should prove a valuable tool to the palæo-serologist.

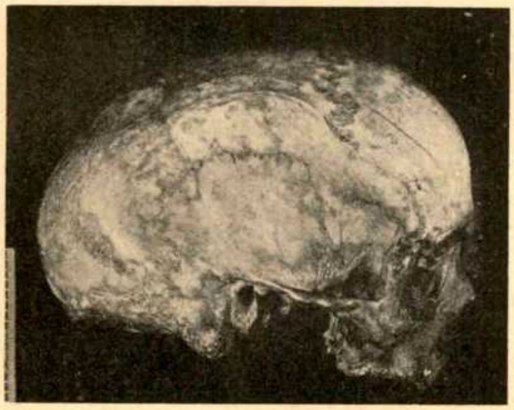

Fig. 1. The 'English' skull attributed to Emanuel Swedenborg. (*Norma lateralis*)

As it was reported (Henschen, personal communication) that large quantities of lead salts were present in the bones, a study was made on control material of known blood group to determine whether increased quantities of lead salts would affect the results of blood testing. The normal quantity of lead present in the long bones is 1·88 mgm. per 100 gm. In a series of tests this quantity was increased until it reached twice the normal value. No effects on the results of blood grouping were noted.

While the use of palæo-serological technique has proved its value in the identification of human remains, it has not contributed to any decision in the case discussed here. However, it has been established that on the basis of blood grouping the 'English' skull has an equal claim with the Uppsala skull to be that of Swedenborg, and that it should be included in further investigations. Tests being carried out in Sweden, under the direction of Prof. Henschen, may prove of greater assistance in distinguishing between the two skulls. It is expected that results of their examination will be published in the *Acta Regiae Societatis Scientiarum Upsaliensis*.

I am indebted to Mr. G. C. Ross for the estimations of nitrogen content of the bones quoted in this communication.

ABNORMAL HUMAN HÆMOGLOBINS

Human Hæmoglobin *E*: the Chemical Effect of Gene Mutation

THREE of the many abnormal variants of human adult hæmoglobin (*A*) occur in high frequency in certain areas of the world. They are sickle cell hæmoglobin (*S*), hæmoglobin *C* and hæmoglobin *E* (ref. 1). All these are thought to be caused by mutant genes inherited in a Mendelian manner. Such evidence as is available suggests that the genes for hæmoglobins *S* and *C* are allelic or closely linked[2]. The only family so far known in which hæmoglobin *E* occurred with another abnormal hæmoglobin (*S*) was one studied in Turkey by Aksoy and Lehmann[3]. The evidence for allelism, or close linkage, of the two genes was conflicting, but the authors felt that it was more in favour of allelism than against.

Comparisons of the chemical structure of hæmoglobins *S* and *C* with that of normal hæmoglobin (*A*) have not only confirmed the allelic nature of the hæmoglobin *S* and *C* genes, but have also shown the effects of these mutations on the primary chemical structure of hæmoglobin[4]. We now wish to report similar studies on hæmoglobin *E* which we undertook in order to investigate the chemical effect of this mutation and the chemical and genetic relationship between hæmoglobin *E* and the other abnormal hæmoglobins.

Hæmoglobin *E* was discovered in 1954 by Itano, Bergren and Sturgeon[5] in an American patient of Guatemalan, Spanish and Hindu origin—and in his family—by its abnormal electrophoretic mobility. The gene for hæmoglobin *E* has since been found with high incidences among Burmese and Siamese and some Indonesian, Ceylonese and Malaysian populations[6]. Single instances have been found in India, Persia, the Philippines[6], and among the Eti-Turks[3] (who have a high incidence of the sickle cell gene). It is interesting to note that the hæmoglobin *E* gene is found with high frequency in south-east Asia, whereas the hæmoglobin *S* and *C* genes are found in highest incidence among the Negroes of Africa[1]. In other words, they are geographically widely separated, but all three forms resemble one another in occurring very much more frequently than the other abnormal hæmoglobins. The chemical relationship between hæmoglobins *A*, *S* and *C* was reported by us[4] to be very close indeed, since it involved a replacement of the same glutamyl residue in hæmoglobin *A* by a valyl residue in hæmoglobin *S* and a lysyl residue in hæmoglobin *C*. Since the countries in which the hæmoglobin *S* and *C* genes occur are close together, and since the gene for hæmoglobin *E* occurs mostly in a separate region, it seemed possible that hæmoglobin *E* is not so closely related to *S* and *C*. This was found to be the case; a different part of the hæmoglobin molecule is affected by the mutational change.

On moving-boundary or paper electrophoresis at *p*H 8·6 (ref. 7) hæmoglobin *E* moves close to hæmoglobin *C* but slightly faster; on the other hand, at *p*H 6·5 its position is close to hæmoglobin *S*, though just behind it. This contrasts with the behaviour of hæmoglobins *A*, *S* and *C*, which migrate in the same relative order at *p*H 8·6 and at *p*H 6·5, hæmoglobin *A* being the fastest and hæmoglobin *C* the slowest. The intervals between them are almost equal. Hence, the effective net charge difference between hæmoglobins *A* and *E* at *p*H 6·5 cannot be the same as that between hæmoglobins *A* and *C*. The amino-acid compositions of hæmoglobins *A* and *E* are not significantly different[7]. The number of sulphydryl groups found by amperometric titration are the same in both hæmoglobins *A* and *E* (ref. 7); the solubility of hæmoglobin *E* is about the same as hæmoglobin *A* (ref. 5). Hence the difference between the hæmoglobins *A* and *E* is likely to be small and probably involves charged groups.

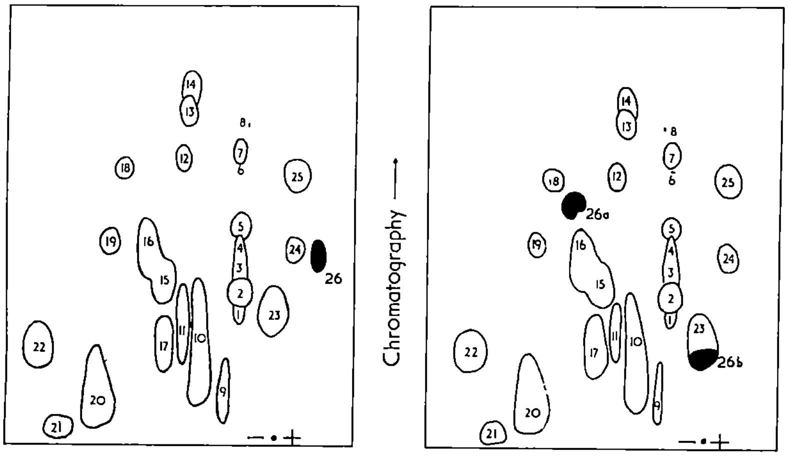
In the present work, hæmoglobin *E* from individuals known to be homozygous for the hæmoglobin *E* gene was denatured by heat at *p*H 8. It was then digested with trypsin at *p*H 8, following the course of the breakdown by alkali uptake in a *p*H-stat[4]. At the end of the reaction a core resistant to trypsin was precipitated at *p*H 6·5. Treatment with hydrochloric acid–acetone removed the hæm group from the core, which could then be completely solubilized by digestion with chymotrypsin[4].

Such tryptic and chymotryptic digests of hæmoglobin *E* yielded mixtures of peptides which were compared with those of hæmoglobin *A* in two ways. First, they were separated by fingerprinting[4], and secondly, by paper electrophoresis in the pyridine–acetic acid buffer at *p*H 6·4 (ref. 8) and examination of the peptide bands so formed by descending chromatography with *n*-butyl alcohol/acetic acid/water (4 : 1 : 5)[9].

When fingerprints of the chymotryptic and tryptic digests of hæmoglobin *E* were compared with those of hæmoglobin *A*, all the peptides occupied the same positions except peptide 26, which had been replaced by a new peptide, called 26*a*, in the hæmoglobin *E* tryptic digest (Fig. 1). Separation of the peptides by the second method revealed another new peptide, called 26*b*, in the tryptic digest of hæmoglobin *E*. It therefore appears that one peptide present in the tryptic digest of hæmoglobin *A* is replaced by two new ones in hæmoglobin *E*. No other changes have so far been found. Within the limits of our experimental method[4], the amino-acid compositions of the unchanged peptides in the tryptic and chymotryptic digests were found to be the same in hæmoglobins *A* and *E*.

The hæmoglobin peptides *A*–26, *E*–26*a* and *E*–26*b* were isolated by eluting the appropriate peptide bands obtained by paper electrophoresis of the tryptic digests at *p*H 6·4. The hæmoglobin *A* peptide 26 required no further purification. The hæmoglobin *E* peptide 26*a* was purified by repeating the electrophoresis at *p*H 6·4, and the hæmoglobin *E* peptide 26*b* by descending chromatography with *n*-butyl alcohol/acetic acid/water (4 : 1 : 5)[9].

The amino-acid sequences of the differing peptides were determined by the techniques of Sanger[10] and of Edman[11]. Quantitative amino-acid analysis by two-dimensional paper chromatography[12] showed the composition of the hæmoglobin *A* peptide 26 and those of the hæmoglobin *E* peptides 26*a* and 26*b* to



Haemoglobin A

Haemoglobin E

be as shown in Table 1 The composition of the hæmoglobin *A* peptide has been confirmed by analysis on the 'Spinco' Model 110 Moore and Stein automatic analyser When the compositions of the two hæmoglobin *E* peptides are added, they account for all the amino-acids present in the normal peptide with the addition of a single lysine residue in place of a glutamic acid

Table 1 COMPOSITION OF HÆMOGLOBIN *A* PEPTIDE 26 AND OF HÆMOGLOBIN *E* PEPTIDES 26*a* and 26*b* (EXPRESSED AS RESIDUES OF AMINO-ACID PER MOLE OF PEPTIDE)

	Hæmoglobin *A* peptide 26	Hæmoglobin *E* peptide 26*a*	26*b*
Aspartic acid	2	—	2
Glutamic acid	2	—	1
Alanine	1	1	—
Glycine	3	1	2
Leucine	1	1	—
Valine	3	—	3
Arginine	1	1	—
Lysine	—	—	1

Partial amino-acid sequences of the peptides were obtained from the results of partial acid hydrolysis, and end-group determinations of the fragments by Sanger's 1-fluoro-2,4-dinitrobenzene method[11] The N-terminal sequences of the hæmoglobin *A* peptide 26 and the hæmoglobin *E* peptide 26*b* were found by examining the dinitrophenol-peptides obtained by partial acid hydrolysis of the dinitrophenol-derivatives of the two peptides, and also by three steps of the Edman degradation[11] using the modification of Sjoquist[13] The remaining portion of the sequence of the hæmoglobin *A* peptide 26 was finally determined by digestion with elastase[14] and quantitative amino-acid analysis[12] of the resulting fragments When the peptide was heated in dilute acetic acid[15], it was found that nearly two molecules each of aspartic acid and valine had been split from the peptide, leaving the rest intact As shown in Fig 2, it is still not yet possible to give a complete sequence for the hæmoglobin *E* 26*b* peptide, although peptides of structure glu(val,gly) and val-gly must be fitted into the undetermined region in some way It is highly likely that the sequence in the hæmoglobin *E* 26*b* peptide corresponds exactly to that of the hæmoglobin *A* 26 peptide segment except that the C-terminal lysine replaces the glutamic acid in hæmoglobin *A* 26 peptide

Hæmoglobin *A* 26 val-asp-val- asp-glu-val-gly -gly - *glu* - ala-leu-gly-arg
Hæmoglobin *E* 26*b* val-asp-val-(asp-glu-val-gly)-gly - *lys*
26*a* ala-leu-gly-arg

Fig 2 Amino-acid sequences of hæmoglobin *A* peptide 26 and of hæmoglobin *E* peptides 26*a* and 26*b*

The occurrence of amide groups in these peptides has yet to be investigated, but the electrophoretic behaviour of the parent hæmoglobins *A* and *E* suggests that the glutamic acid which is replaced has a free carboxyl group

It is assumed that hæmoglobin *E* contains two equal half-molecules, as do hæmoglobins *A* and *S* (ref 16) Fig 2 shows that the change in hæmoglobin *E* resides in a replacement of a glutamyl residue of hæmoglobin *A* by a lysyl residue in hæmoglobin *E* This is the only difference so far detected among nearly 300 amino-acids of the hæmoglobin half-molecule The amino-acid substitution is like that found in hæmoglobin *C* (ref 4), involving a change of two charges, and the two proteins have a similar electrophoretic mobility at *p*H 8 6, but in this case it occurs in a different tryptic peptide and hence in a different part of the protein molecule

It is interesting to note that, just as in the case of hæmoglobins *S* and *C*, the genetic mutation which is responsible for producing hæmoglobin *E* expresses itself as a replacement of a single amino-acid by another We can only guess that this alteration is somehow functionally important, and confers a selective advantage on its bearer which is sufficiently high to account for its frequent occurrence[17] The chemical mechanism underlying the effect is as yet obscure The amino-acid change which we find explains the electrophoretic mobility of hæmoglobin *E* at *p*H 8 6, but not its behaviour at *p*H 6 5 While it cannot be stated with complete assurance that there is no other amino-acid alteration in the hæmoglobin *E* molecule, no other charge difference has so far been detected among the peptides, nor have any differences in their amino-acid compositions been found

Aksoy and Lehmann[3] have suggested that the gene for hæmoglobin *E* is an allele of, or closely linked to, the gene for hæmoglobin *S* (and hence to that for hæmoglobin *C*) In these last two proteins the change in the identical amino-acid suggests that the mutations occupy identical loci in the deoxyribonucleic acid chain forming the hæmoglobin gene The locus of the hæmoglobin *E* mutation is likely to be some distance away from the *S* and *C* loci, but may, nevertheless, be closely linked in the usually accepted genetic sense The finding that peptide 4 (hæmoglobin *S* and *C* mutations) and peptide 26 (hæmoglobin *E* mutation) are found to be in the same β-peptide chain of hæmoglobin[18] supports the idea of close linkage

We wish to thank Drs H Lehmann and E R Huehns (London) for generously supplying the samples of hæmoglobin *E* used in this investigation, Dr G Braunitzer (Munich) for his gift of a large quantity of hæmoglobin *A* peptide 26, and Drs M F Perutz and F H C Crick (Cambridge) and Dr H Lehmann for their helpful interest in this work One of us (J A H) is indebted to the Medical Research Council for a Scholarship

Hæmoglobin 'Bart's': a Fœtal Hæmoglobin without α-Chains

In a previous communication one of us reported[1] that normal fœtal hæmoglobin (*F*) consists of two kinds of polypeptide chains One of these (α) is identical with the α-chain of adult hæmoglobin, while the other (γ) is different from its adult counterpart (β) and seems to be characteristic of the fœtal form (To avoid confusion in nomenclature of the hæmoglobin chains, it has been decided to call the chains of hæmoglobin *F*, α and γ and not α and β-fœtal as in ref 1) A fœtal hæmoglobin with an abnormally high anodic electrophoretic mobility was discovered at St Bartholomew's Hospital in an infant whose red-cell morphology resembled that seen in thalassæmia[2] It was called hæmoglobin 'Bart's' We have now found that this consists of γ-chains only

Fresh blood from an infant with hæmoglobin 'Bart's' was made available by the courtesy of Dr H Kohler, of Birmingham A purified solution, containing about 4 mgm of hæmoglobin 'Bart's' in 15 ml, was obtained by elution from paper electrophoretograms This solution was adjusted to *p*H 6 9 and heated in a boiling water-bath for 20 min to precipitate the hæmoglobin This was dissolved in 0 1 *N* hydrochloric acid and the hæm extracted with acid acetone[3] The dried globin was suspended in 0 6 ml of 2 per cent ammonium bicarbonate buffer at *p*H 7 9, and digested by addition of 0 05 mgm of trypsin at 38° C After 2 hr the solution was evaporated and re-evaporated from acetic acid to sublime the ammonium carbamate formed A solution of chromatographically purified hæmoglobin *F* (ref 1) of the same concentration was treated in exactly the same way in a parallel experiment The digests were compared with a normal tryptic digest[1] of hæmoglobin *F* by both one-dimensional paper electrophoresis at *p*H 6 4 and by fingerprinting[4]

The 'fingerprint' of hæmoglobin 'Bart's' is shown in Fig 1 in comparison with those of hæmoglobin *F* and the α- and γ-chains of hæmoglobin *F* (ref 1) It is apparent that all the α-chain peptides are missing from hæmoglobin 'Bart's' and that it consists solely of γ-chains Its sedimentation constant is indistinguishable from that of *A* (R A Kekwick), which suggests that its molecular weight is about 68,000 and the globin a tetramer

Jones, Schroeder, Balog and Vinograd[5] have found that hæmoglobin *H* consists solely of β-chains of adult hæmoglobin associated in a tetramer Hæmoglobin 'Bart's', therefore, is the exact counterpart in the fœtal system of hæmoglobin *H* in the adult system Hæmoglobin *H* is only found in the presence of the gene for thalassæmia The blood picture of infants with hæmoglobin 'Bart's' is like that in thalassæmia, but this does not persist into later life, nor do the children develop an abnormal hæmoglobin There are then two possible explanations for the production of an all γ-chain hæmoglobin There may be an over-production of the γ-chains However, from our present data we cannot be certain that there does not exist a small chemical difference between the γ-chains in hæmoglobin 'Bart's' and those in hæmoglobin *F* Alternatively, the production of α-chains may be inhibited, in which case, since the children with hæmoglobin 'Bart's' do not develop hæmoglobin *H*, the α-chains of hæmoglobin *A* and *F*, although chemically identical, do not appear to be controlled by the same gene Thus in a Greek boy with thalassæmia in whom, as is typical for this condition, hæmoglobin *F* had persisted beyond the age of infancy, a small amount of hæmoglobin 'Bart's' was

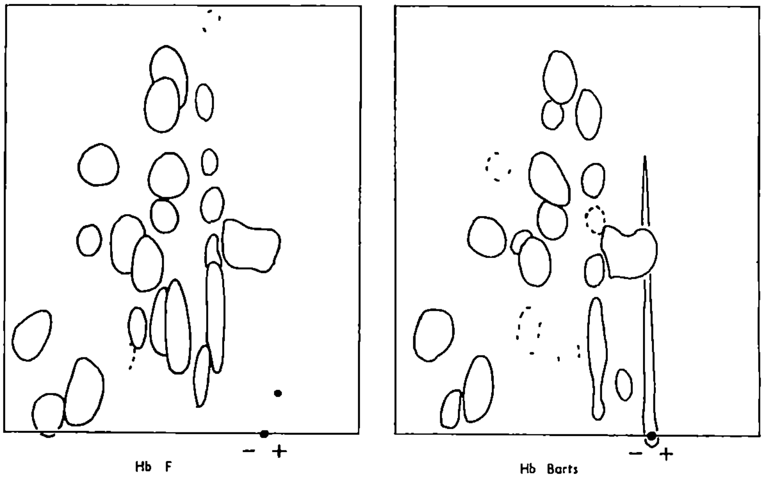

Fig 1 Tracings of fingerprints of the tryptic digestions of hæmoglobin 'Bart's' and hæmoglobin *F*

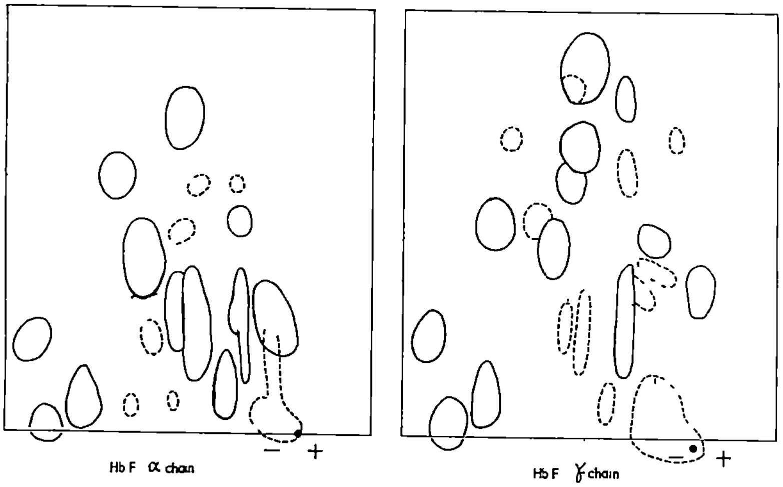

Fig 2 Tracings of fingerprints of the tryptic digestions of the chains of hæmoglobin *F*

also found but no hæmoglobin *H*[6] This could be interpreted as demonstrating the independence of the production of the α-chains for hæmoglobins *A* and *F* On the other hand, in an adult woman from Israel with a thalassæmia-like blood picture, more than 80 per cent of hæmoglobin *A* and only traces of hæmoglobin *F* were found, but 8 per cent of hæmoglobin 'Bart's' and 5 per cent of hæmoglobin *H*[7] Of her four children one also possessed hæmoglobins *A*, 'Bart's' and *H*, but only a trace of *F* This represents a strong inhibition of the fœtal α-chain formation with only a weak inhibition of that of the α-chains for hæmoglobin *A*

Several infants with hæmoglobin 'Bart's' have now been seen, always associated with normal hæmoglobin *F*, and it is interesting that in these infants the γ-chains of fœtal hæmoglobin should be capable of a separate existence, even though α-chains are being produced for both hæmoglobins *A* and *F* No reports of hæmoglobin consisting entirely of α-chains have yet appeared, but it would not be surprising if such chains could also exist on their own

MECHANISM OF IMMUNOLOGICAL UNRESPONSIVENESS

By Prof. CHARLES F CRAMPTON*, FRED R FRANKEL and Mrs J. L RODEHEAVER
Departments of Pathology and Biochemistry, College of Medicine, University of Florida, Gainesville

CONDITIONS of immunological unresponsiveness which vary in specificity, completeness and duration have been induced in new-born rabbits by administering small amounts of soluble proteins at birth[1–4], and in adult rabbits by the injection of massive doses[5] of antigens, or by the prolonged administration of moderate amounts of antigens[6,7] In the hope of emphasizing pathways of antigen distribution that are essential for the establishment of an immune response, studies were undertaken to determine whether the fate of labelled antigen in unresponsive rabbits differs from the fate in normal rabbits which are potentially responsive[8] For this purpose, New Zealand white rabbits were rendered specifically unresponsive by means of repeated intraperitoneal injections of iodoproteins begun within 12 hr of birth[9] The iodo-ovalbumin and the iodobovine serum albumin which were injected contain 8–10 per cent of iodine and when injected intraperitoneally to normal adult rabbits they consistently evoke the production of precipitating humoral antibodies specific, in part, for their determinant diiodotyrosine residues

In no case, however, were precipitating antibodies found in the sera of rabbits which had been injected repeatedly 4–6 months from the time of birth The methods used to trace the iodoproteins were essentially the same as those employed in previous studies[8] Preparations of the iodoproteins labelled with iodine-131 were injected intravenously to normal and unresponsive rabbits Measurements were made after intervals of 2 min –24 hr of that portion of the persisting iodine-131 that was insoluble in aqueous 7 per cent trichloracetic acid and in neutral alcohol and acetone Because the radioactive iodine is an integral part of the determinant groups of the iodoproteins, it is felt that measurements of protein-bound iodine-131 trace the fate of material that is potentially antigenic, possibly in contrast to measurements of the total persisting isotope It was found that the labelled iodoproteins were eliminated from the blood and distributed among the organs of unresponsive rabbits in the same way as in normal, adult rabbits After a day, less than 0 5 per cent of the total injected iodoprotein remained in the blood of rabbits of both types Since the inability to form antibody induced by the present procedures does not result in a persistence or 'tolerance' of the antigens in the unresponsive rabbits, there is no evidence that the iodoproteins are 'recognized-as-self' by the unresponsive rabbits, or that the unresponsiveness depends on a mechanism for eliminating the iodoproteins more rapidly than normal Inasmuch as the patterns of intracellular localization in the cytoplasmic granules of the livers and spleens of the unresponsive rabbits were exactly the same as those observed previously with iodo-ovalbumin and certain azoproteins[8,10], it is clear that the presence of foreign antigenic material in cytoplasmic granules, while possibly a condition that precedes or is necessary for antibody formation[11], is not in itself a condition that leads inevitably to the production of measurable amounts of precipitating antibody

---

* Scholar in Medical Science, The John and Mary R Markle Foundation

Of the many possible interpretations of these findings only one will be considered, namely, that the presence of antigen or haptenic fragments of degraded antigen may actually function to forestall antibody formation It is proposed that antibody formation is initiated as usual in a small number of susceptible cells whenever normal or unresponsive rabbits receive antigen However, the first molecules of antibody that are formed are likely to encounter cytoplasmic granules that contain residual antigen derived from the final injection, or (in the case of unresponsive rabbits) partially degraded haptenic residues remaining from previous injections of antigen Intracellular antigen–antibody reactions at appropriate loci could release the hydrolytic enzymes that are normally retained within the membranes of granules such as the lysosomes[12]

If the damage inflicted on essential structures by the reaction itself, or by the enzymes released or activated through the reaction, were sufficient to annihilate such cells, there would fail to be established a permanent line of cells that possessed the specific information necessary for antibody formation during the time when undegraded, antigenically potent antigen was still present in the rabbit Direct evidence is already at hand that the addition of antigen to tissue breis or to sera that contain specific antibody results in the activation of proteases[13–15] It is anticipated that a similar activation will follow the addition of antibody to sera, to homogenates of tissue, or to subcellular fractions that contain specific antigen Damage by proteases that are activated by immunological reactions has been suggested repeatedly over the years[14,16] as a reasonable basis for pathological changes at the tissue-level that occur in states of hypersensitivity The present suggestion is that under certain conditions such damage would not extend beyond individual cells in which antibody formation had been initiated The fact that induced immunological unresponsiveness is not permanent, unless antigen is continually administered[4], is attributed to the gradual loss (by degradation or by dilution) of haptenic residues from the potential antibody-forming cells, or to a fortuitous asymmetric distribution to daughter cells of the discrete granules that contain the antigen

Many more data are required before it will be possible to decide whether a number of phenomena already recorded in the literature are manifestations of some of the cellular events postulated here Insurmountable difficulties may confront attempts to assign microscopically visible effects unequivocally to macroscopically imposed causes, particularly when the effects that are judged as pertinent to the argument could be exceedingly rare events Nevertheless, it may be significant that degenerating, fragmented nuclei are found beside viable, primitive cells in the germinal centres of the lymphoid follicles, particularly during the natural immunization that accompanies bacterial infections[17] This paradoxical phenomenon is enhanced by immunization with antigens ordinarily regarded as innocuous Since a few molecules of antigen may be adequate to initiate antibody formation, while a relatively large amount of antigen may be required to ensure complete annihilation of antibody-forming cells, it is possible that the remarkable action of adjuvants (see ref 18) is to minimize the flood of antigen into the cytoplasmic granules of potential antibody-forming cells so that survival is more probable if the improbable events occur that culminate in antibody formation

It is noteworthy that application of the fluorescent antibody techniques of Coons to adult rabbits has shown that antibody is rarely detectable in cells that take up antigen, where devastating intracellular antigen–antibody reactions would be possible[19] Moreover, the antibody within germinal centres of stimulated lymph nodes is limited not only to individual cells, as in the medullary area, but occurs also "over an area of the follicle involving a number of cells in an indistinct way, often with a particulate distribution between the cells as well"[19] Antibody distributed in this manner may correspond to debris from cells which undertook antibody production while excessive amounts of antigen were still present in cytoplasmic particles On the other hand, antibody, but rarely antigen, is easily detected in members of the plasma cell series[19,20] The superficial injury that plasma cells are liable to suffer as a result of an extracellular antigen–antibody reaction, rather than causing cell death, may form what is frequently overlooked by many theorists, a concrete basis for the specific proliferative stimulus that must underlie the secondary response The mechanism which must be modified (or selected) in order for appreciable amounts of antibody to be formed appears to reside in cells that are highly sensitive to X-irradiation Once it is established, however, the antibody-forming mechanism is remarkably radioresistant[21] Although cells with different morphological properties appear to be involved at the beginning and at the end of the overall process of antibody formation, the striking qualitative differences of these cells with respect to radioresistance might depend upon the cellular locus of antigen–antibody reactions, rather than a fundamental change in cell type Perhaps death is an inevitable sequel to X-ray damage in cells that are also damaged by intracellular antigen–antibody reactions, while antibody-forming cells may survive X-irradiation in the absence of additional intracellular damage from antigen–antibody reactions Very recently, it was suggested[22] that X-irradiation destroys within minutes the ability of cells in lymphatic tissues to derive energy from nuclear phosphorylation reactions The intracellular antigen–antibody reactions postulated here might be expected in addition to derange alternative, cytoplasmic reactions that otherwise could have produced energy utilizable for survival and for eventual repair of the X-ray damage

Many previous theories of antibody formation have failed to provide adequate explanations for the fact that the secondary response is more intense than the primary response (for a discussion, see ref 19) On the other hand, certain versions of the 'selection theory', which currently enjoys much favour[23], appear to neglect the same fact viewed from the other direction, that the primary response is much less intense than the secondary response In the outline of the proposals presented here, the secondary response is assumed to depend upon a stimulation to proliferate that is selective for lines of cells that have inherited, or otherwise acquired, the specific information needed to synthesize antibody, which information was initially established in the few surviving cells that were modified as a result of the primary encounter with antigen The absence of a "suitable environment"[24] that was postulated to account for the failure of appreciable formation of antibody in new-born rabbits, even when competent cells were transferred from normal adult donors, may depend upon a possible deficiency of metabolites essential for survival and necessary to repair the intracellular damage caused by antigen–antibody reactions in individual cells where antibody formation was initiated

That transfer to new-born rabbits of lymphatic tissue from immunized donors is followed by formation of antibody[24] would depend upon the existence in the transferred tissue of cells in which the antibody-forming mechanism is free from potentially lethal intracellular antigen Natural tolerance towards self-materials and experimentally induced tolerance towards homografts, where many of the antigenic determinants that are involved still await chemical characterization, may also depend upon the selective destruction of cells in which auto-antibody formation is initiated The accidental survival of a few such cells, if followed by the passage of the antibody-forming mechanism into cells that are impervious to 'antigen', would explain the development of conditions of auto-immunization

The finding that iodoproteins appear to undergo the same fate in unresponsive rabbits as in normal rabbits has suggested simple mechanisms which might account for specific unresponsiveness and for a number of other immunological phenomena However, it is clear that the experiments have not clarified the ultimate problems of where and how the information necessary for the synthesis of a specific combining site is materialized, or whether this information exists in cells prior to a primary injection of the antigen.

A complete and more critical account of the experimental studies which form the basis of this discussion is being prepared for publication This work was supported by the United States Public Health Research Grants *E*-1296 and *E*-1296(*C*) We are indebted to Dr Joshua L Edwards for many informative and stimulating discussions, and for making available the opportunities and facilities that made the studies possible One of us (F R F) has received support from U S Public Health Service *RG*-4801 (*C2S*1) [May 13

HYDROGENATION OF LIPIDS BY RUMEN PROTOZOA

By DR. D E WRIGHT

Plant Chemistry Division, Department of Scientific and Industrial Research, Palmerston North, New Zealand

IT has been observed by several workers that dietary unsaturated fats are modified in the rumen by hydrogenation Shorland, Weenink and Johns[1] found that the fatty acid composition of ingested plant material was considerably changed by rumen contents In particular, the high content of linolenic acid was markedly reduced, being converted mainly to stearic acid This work was confirmed by Shorland, Weenink, Johns and McDonald[2] when they demonstrated that rumen contents *in vitro* could hydrogenate oleic, linoleic and linolenic acids Other studies on hydrogenation include those by Hoflund, Holmberg and Sellmann[3] using cows fed linolenic acid, Reiser and Reddy[4] with goats fed on a diet supplemented with unsaturated oils, and more recently Garton, Hobson and Lough[5] with sheep The type of micro-organism responsible for the hydrogenating activity has not been determined in these studies

It has been observed that some species of protozoa are able to ingest chloroplasts[6] Since chloroplasts are rich in lipid material, particularly unsaturated fatty acids, it was thought likely that these ciliates may be responsible for at least some of the hydrogenation occurring in the rumen

Rumen contents were collected from a rumen-fistulated cow fed on fresh red clover (*Trifolium pratense*) and the protozoa allowed to settle by gravity Microscopic examination of the protozoa showed a mixed population of holotrichs and oligotrichs, the latter group being mainly Epidinia Washed suspensions of the ciliates were prepared by the procedure described by Oxford[6] using an acetate–bicarbonate–phosphate buffer containing penicillin and neomycin After washing to free them of bacteria, the protozoa were suspended in the buffer with antibiotics to which the substrate and clover starch were added The flasks were incubated under carbon dioxide at 38° or 4° After overnight incubation, the lipid material was extracted from the solution by acidifying with hydrochloric acid and extracting with petroleum ether The fatty acids were isolated by the usual methods and their iodine numbers calculated by the Hanus procedure Under these

Table 1 Hydrogenation of Sodium Linoleate and Linseed Oil by a Suspension of Rumen Protozoa

Incubation temperature	Substrate	Iodine number
4°	Sodium linoleate	162 6
38°	Sodium linoleate	101 2
4°	Linseed oil	160 0
38°	Linseed oil	120 0

conditions, hydrogenation of both linoleic acid and linseed oil was found (Table 1)

The hydrogenation of chloroplast fat was next examined by incubating protozoa with chloroplasts A suspension of chloroplasts was prepared by grinding freshly picked red clover leaves in an end-runner mill with a sucrose–phosphate buffer solution[7] After removing the fibrous material by filtration through muslin, the filtrate was centrifuged at 100*g* for 10 min to remove large plant particles and the supernatant centrifuged at 1,500*g* for 20 min to sediment chloroplasts The chloroplasts were suspended in the acetate–bicarbonate–phosphate buffer plus antibiotics and equal volumes added to two 100-ml conical flasks containing washed protozoa suspensions, one of which had been placed in a boiling water-bath to destroy enzyme activity The flasks were flushed with carbon dioxide and then incubated at 38° C , provision being made for the release of gas from the flasks

After incubating overnight, the boiled control sample was still green in colour, but the test sample was coloured yellow, indicating breakdown of chlorophyll The samples were freeze-dried and the lipids extracted by boiling with diethyl ether The ether solutions were evaporated to dryness, taken up in petroleum ether and the solvent removed *in vacuo* The lipids were saponified and fractionated into water-soluble, non-saponifiable and fatty acid fractions The fatty acids were converted to the methyl esters and analysed by gas-liquid chromatography Considerable differences were noted between the test and control sample fatty acids (Table 2)

The composition of the C^{18} acids in the boiled control sample is typical of red clover chloroplast lipid (Weenink, R O , personal communication)

Table 2 Comparisons between C^{18} Fatty Acid Composition of Chloroplast Lipids incubated with Live or Dead Rumen Protozoa

Fatty acids weight per cent

Sample + Chloroplasts	Saturated	Unsaturated		
		mon-	di-	tri-ene
Live protozoa	17 5	10 6	27 6	44 3
Boiled protozoa	10 7	16 2	2 8	70 3
Difference	+6 8	−5 6	+24 8	−26 0

There has been considerable conversion of triene acid to diene acid and monoene to stearic acid Only a slight conversion of diene to monoene seems to have occurred This is rather surprising since it was shown above that protozoa could hydrogenate linoleic acid Reiser[8] suggested that rumen contents convert linolenic acid merely to linoleic acid although Shorland *et al* [1] showed further hydrogenation of linoleic acid to monoene and saturated acids Since a considerable amount of linolenic acid still remained in these protozoa experiments, there must have been an excess of unsaturated lipid present and it may be possible that the enzyme or enzymes responsible for hydrogenation show some degree of specificity and attack the triene and monoene acids preferentially Since little is known about the mechanisms of enzymic hydrogenation, this must remain speculative at the moment

The non-saponifiable material from both samples was yellow in colour, had similar intensities and spectra typical of a carotene–xanthophyll mixture In spite of the carotene being highly unsaturated, little hydrogenation of the pigment has occurred This is in agreement with the observations made by Shorland, Weenink, Johns and McDonald[2]

In spite of attempts to wash the protozoa clean of external bacteria, some bacteria were undoubtedly present inside the ciliates Their role in hydrogenation is difficult to assess , but it seems likely that they were not present in great enough numbers to have much effect Preliminary experiments using washed suspensions of rumen bacteria suggest that bacteria do not contribute a great deal to the hydrogenation occurring in the rumen It is interesting to speculate whether fluctuations in the population of protozoa could be correlated with the seasonal variation in iodine numbers of milk fat noted in New Zealand[9]

Further studies on the role of bacteria and individual species of protozoa in lipid metabolism are in progress I would like to thank Miss J Michael for technical assistance, and Dr J C Hawke and Miss J Cook, of the Fats Research Laboratory, Wellington, for the gas–liquid chromatography data

FORMATION OF THE PORPHYRIN RING

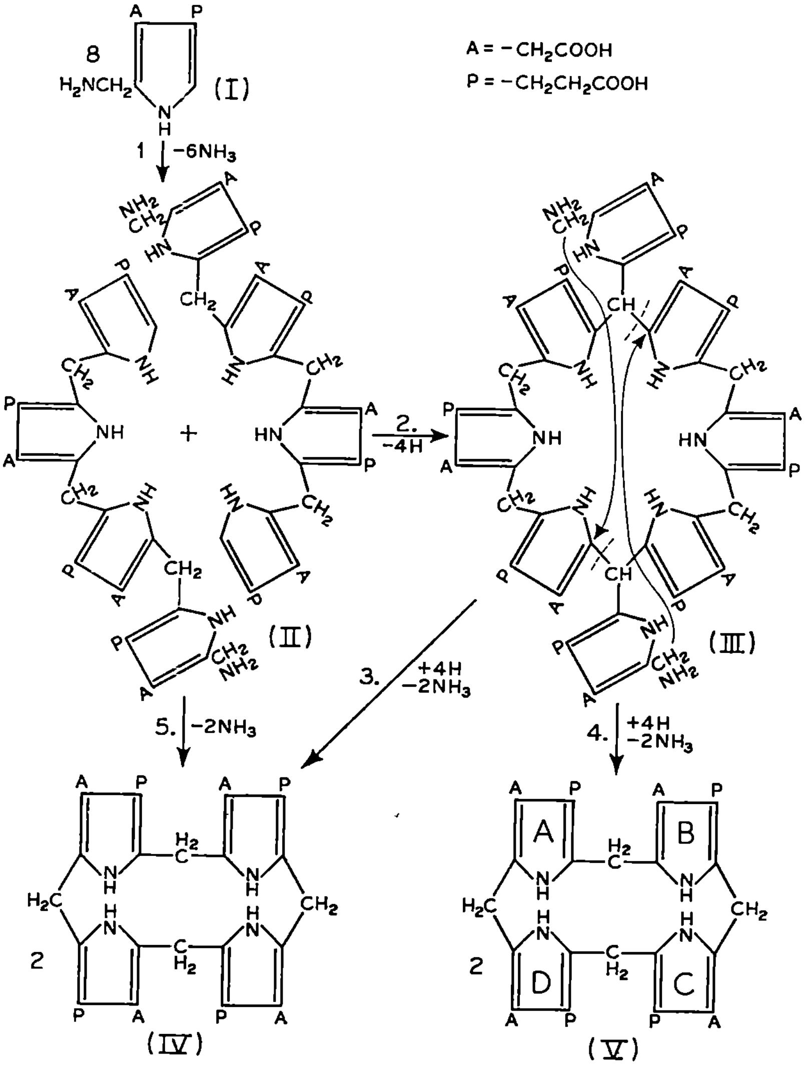
By Prof JONATHAN B. WITTENBERG*

Departments of Physiology and Biochemistry, Albert Einstein College of Medicine, New York 61, New York

IT is generally agreed that the naturally occurring porphyrins arise through the condensation of four molecules of porphobilinogen (I) However, it has proved very difficult to formulate a sequence of reactions leading uniquely from porphobilinogen to the type III and type I porphyrins Several years before any of the reactions leading to porphyrin formation were recognized, Turner[1] had realized that the essential clue to the understanding of the cyclization of the porphyrin ring was to be found in the behaviour of tripyrrylmethanes, established by Corwin *et al* [2,3] Shemin, Russell and Abramsky[4] and Bogorad and Granick[5] have elaborated these ideas In the course of the isolation of isotopically labelled hæmin from duck red blood cells[6], Shemin and I (unpublished work) encountered a colourless, stable, intensely radioactive, protein-bound material, which was thought to be a polypyrrole On the strength of this finding, compounds containing several pyrrole rings were considered as possible intermediates in the condensation of porphobilinogen (I) to the uroporphyrinogens (IV, V), the parent substances of the porphyrins If Turner's tripyrryl-methane hypothesis is coupled to the idea that the rearrangements leading to the type III porphyrins occur within a single large molecule, a mechanism for porphyrin formation emerges which not only satisfies all the chemical requirements put forth below but also provides a rational interpretation of the results of Bogorad's[7-9] elegant enzymatic studies This formulation has the virtue that it reveals the unique structure of the type III porphyrins to be a necessary consequence of the chemical structure of the key intermediate, a cyclic octapyrrole (III), in their formation

---

* Senior Research Fellow (*SF* 57), U S Public Health Service



The primary requirement to be fulfilled by the octapyrrole hypothesis is that it must lead to the formation of only type III and type I uroporphyrinogens (V and IV respectively) since type II and IV isomers are not formed enzymatically[7,8], and type II and IV porphyrins do not occur in Nature Furthermore, the isomeric specificity must be independent of the action of enzymes and reside in the chemical nature of the reaction since, in the presence of hydrochloric acid, (I) is converted largely to (V), with the formation of lesser amounts of (IV)[10,11] These conditions are met by reactions 4, 5 and 3 In addition, the octapyrrole hypothesis fulfils all the following subsidiary requirements all four pyrrole rings of the porphyrin must arise from a single common precursor (I), in agreement with the very exact equivalence of the isotope concentrations in the neutral and acidic pyrroles of hæmin formed from isotopically labelled precursors[6,12,13] All of (I) consumed in the reaction must be converted to porphyrin without the obligate formation of pyrrolic by-products, in agreement with the more than 90 per cent[14] or 80 per cent[8] conversion of (I) to porphyrins achieved enzymatically, or the 77 5 per cent conversion achieved in the presence of hydrochloric acid[11] All four of the methene bridge carbon atoms must be derived from the aminomethyl side-chain of (I), in agreement with the isotope data[6]

Most of the schemes of porphyrin formation hitherto proposed (refs 4, 5, 11, 17, and reviewed in refs 15, 16) do not account for the formation of porphyrins I and III uncontaminated by other isomers, nor can they account for the very high yields of uroporphyrin-III formed from porphobilinogen

Formaldehyde may be a product of the enzymatic and non-enzymatic conversion of (I) to porphyrin[4] This would constitute strong evidence against the present proposal only if the formaldehyde were shown to arise in stoichiometric amounts from the aminomethyl group of (I)

The octapyrrole hypothesis may be stated in conjunction with Bogorad's recent enzymatic work[7-9] He finds[7] that the enzyme porphobilinogen deaminase converts (I) to (IV) However, since a second enzyme named 'uroporphyrinogen isomerase' has as its sole substrate a product (different from IV) of the action of porphobilinogen deaminase on (I) (ref 8), it appears necessary to postulate that an as yet undetected colourless compound is the primary product of the action of porphobilinogen deaminase The structure of this material must be such that it is easily convertible, either spontaneously or under the further action of porphobilinogen deaminase, to (IV) (reaction 5) The suggestion is advanced that this unknown compound is the linear tetrapyrrole (II), and that the primary action of porphobilinogen deaminase is to convert porphobilinogen (I) to a linear tetrapyrrole (II) (reaction 1)

The enzyme 'uroporphyrinogen isomerase' acts to yield uroporphyrinogen-III (V) as its first detectable product[8,9] The suggestion is advanced that the function of this enzyme is to condense two molecules of (II) (reaction 2), thus introducing the two tripyrrylmethane structures of (III), and the primary product of its action is the cyclic octapyrrole (III) The cyclic octapyrrole is considered to undergo re-arrangement, either spontaneously or under the further action of the 'uroporphyrinogen isomerase' preparation, to yield two molecules of uroporphyrinogen-III (V) (reaction 4) (An analogous reaction leading to (IV) (reaction 3) will be shown to be less probable)

The overall result of this sequence of reactions is the interchange of the pyrrole moieties destined to form rings *D* of the porphyrins between two tetrapyrroles, with a consequent reversal of the position of the rings *D*, relative to the other pyrrole rings of the tetrapyrroles

An approximate model of (III) demonstrated that reactions 4 and 3 can take place only if the two asymmetric tripyrrylmethane carbon atoms are of the same configuration, and that if this is so the two 'branch' pyrroles must lie on the same side of the plane of the major ring The entire structure can be bent so that the 'branch' pyrroles pass each other and their aminomethyl groups are brought into apposition with the alpha positions of the pyrroles opposite in the ring The simultaneous attack of both aminomethyl groups on the appropriate pyrrole alpha carbon atoms (indicated by arrows in the figure) with consequent scission (indicated by dotted lines) of both tripyrrylmethane moieties leads to rearrangement of (III) to two molecules of (V) (reaction 4) The preferential formation of uroporphyrinogen-III (V) would appear to be a consequence of interactions between the carboxyethyl side-chains of the 'branch' pyrroles with the side-chains of the adjacent pyrroles of the major ring The model shows these to lie in close proximity

Reactions analogous to the foregoing have been described[3,18]

A formulation similar to the foregoing but involving only four pyrroles is ruled out because it was not possible to construct a model of a ring with only three pyrroles

These considerations lead to the prediction that the final ring-closure leading to the porphyrins should occur between rings *A* and *D* Bonnett *et al* [19], on the basis of structural considerations, feel that ring closure of the chromophore of vitamin B_{12} must also occur between rings *A* and *D*, the biogenesis of this molecule is certainly similar to that of the porphyrins[19-21]

Robinson[22] suggested that the initial step in the formation of the type III porphyrin is attack by the aminomethyl group of a porphobilinogen molecule (corresponding to ring *D* of the porphyrin) at the $C_{(2)}$ of a second molecule (corresponding to porphyrin ring *A*) The aminomethyl group, initially at $C_{(2)}$, is regarded as migrating to $C_{(5)}$ of the ring Repetition of the process leads to type III porphyrin, the final ring closure being facile Bullock *et al* [23] have put forward an essentially similar idea, but differing in that the initial attack is thought to be by the aminomethyl group of a porphobilinogen molecule destined to form porphyrin ring *A*, on $C_{(2)}$ of a second molecule destined to form ring *D* These latter authors invoke carbonium ions to explain the migration of the alpha-substituents Either of these chemically elegant postulations will explain the preferential formation of type III porphyrins, and, in addition, fulfil the requirements for the reaction enumerated above However, they are not consistent with the known formation of uroporphyrinogen-I from an intermediate in the enzymatic synthesis of uroporphyrinogen III Further, since the initial, rather than the final, reaction occurs between porphyrin rings *A* and *D*, these postulations cannot provide a facile explanation of the formation of vitamin B_{12}

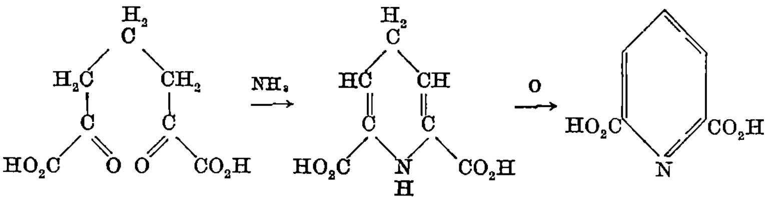
SYNTHESIS OF DIPICOLINIC ACID FROM αε-DIKETOPIMELIC ACID

The late JOAN F. POWELL and R E. STRANGE
Microbiological Research Establishment, Porton, Salisbury, Wilts

CALCIUM dipicolinate is a constituent of resting spores of *Bacillus* species and is excreted during spore germination[1] It is not found as a constituent of non-sporulating vegetative cells but is synthesized during spore formation Vegetative cells and spores of *Bacillus* species contain αε-diaminopimelic acid which, on removal of one amino-group, cyclization and oxidation, would give rise to dipicolinic acid The L-amino-acid oxidase of *Neurospora crassa* oxidizes *meso* diaminopimelic acid with the production of ammonia equivalent to the removal of one amino-group of the amino-acid[2,3] The product has no free amino- or keto-groups Work[3,4] suggests that the α-keto-ε-aminopimelic acid formed may cyclize immediately to form a six-membered ring compound If this is so, then the product without oxidation could be a reduced form of dipicolinic acid Evidence of the conversion of diaminopimelic acid to dipicolinic acid in the presence of sporulating cells of *Bacillus cereus* var *mycoides* was obtained by Perry and

Foster[5], but the efficiency of the reaction was low In the present work, αε-diketopimelic acid has been investigated as a possible intermediate in the biosynthesis of dipicolinic acid by bacteria The diketo-acid was prepared by the method of Blaise and Gault[6]

When disintegrated cells of a laboratory strain of *Bacillus cereus* were incubated in air with αε-diketopimelic acid, a slow oxidation occurred (Q_{O_2} *c* 1) and there was a decrease in free ammonia as determined by the Conway method The rate of oxidation was markedly increased (Q_{O_2} *c* 7) by the addition of ammonium chloride The reaction was allowed to proceed in Warburg flasks in 100 m*M* sodium potassium phosphate buffer, *p*H 7 3, with 10 m*M* diketopimelic acid and 20 m*M* ammonium chloride The volume of the reaction mixture was 2 5 ml and each flask also contained 40 mgm (dry weight) of freshly reaped, washed disintegrated cells from 12-hr strongly sporulating cultures in potato extract medium[7] The ultra-violet absorption spectrum of the reaction mixture showed peaks at 2700 and 2775 A , thus resembling dipicolinic acid It seemed possible that the reaction sequence was as follows



I II III

In these experiments, the production of ultra-violet light-absorbing material was measured, after protein precipitation, by taking difference spectra, that is, the difference in absorbency between reaction mixtures with and without ammonia The addition of diphosphopyridine nucleotide to the reaction mixtures did not improve the rate of oxidation of the diketo acid The reaction proceeded with the fixation of 60–80 per cent of the calculated amount of ammonia required for the complete conversion of I to II and the oxygen uptake was roughly 80 per cent of that required for the formation of one double bond, that is, for conversion of II to III The observed increase in the intensity of the ultra-violet absorption spectrum, however, approached only 50 per cent of that required for the complete conversion of I to III The highest rates of oxidation of the keto acid occurred in the presence of an ammonium salt as amino donor Glucosamine, glutamic acid and L-alanine were tested as amino donors they gave slow and less complete oxidation which was not improved by the addition of pyridoxal phosphate Glutamine, however, gave higher initial rates of oxidation than did ammonium chloride The very low Q_{O_2} values obtained for oxidation of diketopimelic acid when no ammonium chloride was added suggested that the oxidizable substrate was, in fact, a reaction product of the keto acid and ammonium ion The oxidative system was remarkably heat-stable compared with that obtained with unheated extract, the rate of oxygen uptake was actually increased in the presence of extract previously heated for 10 min at 100° and centrifuged to remove precipitated material Assuming this oxidative system is required by living cells to synthesize dipicolinate from αε-diketopimelic acid + ammonium ion it would be expected that such a system and/or the substrate are absent from vegetative non-sporulating cells When a comparison was made of the oxidative activity of cell homogenates of asporogenous and sporogenous strains of *Bacillus megaterium*, the asporogenous strain was found to give a higher rate of oxygen uptake than the sporogenous strain In another experiment, disintegrated vegetative cells of *Bacillus cereus* gave a higher rate of oxygen uptake than disintegrated sporulating cells Finally, an extract of disintegrated cells of *Escherichia coli* was examined and was found to be as active in the system as an extract of disintegrated cells of *Bacillus cereus*

When a solution of the calcium salt of diketopimelic acid and ammonium salt was incubated with buffer, *p*H 7 1, no oxygen uptake occurred However, ammonia was fixed and an ultra-violet absorption spectrum developed which was similar to but less intense than that obtained under similar conditions in the presence of cell extract A comparison of the rates of production of ultra-violet absorbing material in the presence and absence of cell extract is shown in Fig 1 After 4 hr at 37° C the yields of product for reactions in the presence and absence of extract were about 44 and 21 per cent of theoretical, respectively, based on the molar extinction coefficient of calcium dipicolinate at 2700 A Higher yields were obtained if incubation was continued for 24 hr When the reaction mixture in which ultra-violet absorbing material had been produced in the absence of cell extract was re-incubated with added cell extract, no oxygen uptake occurred The possibility existed that, in the absence of cell extract, a dihydropyridine-2 6-dicarboxylic acid was produced which gave a similar but less intense ultra-violet absorption spectrum than dipicolinate Isolation of the product was therefore attempted

αε-Diketopimelic acid (40 mgm) was dissolved in water (8 ml) and calcium carbonate (21 mgm) added to form the neutral calcium salt An equal volume

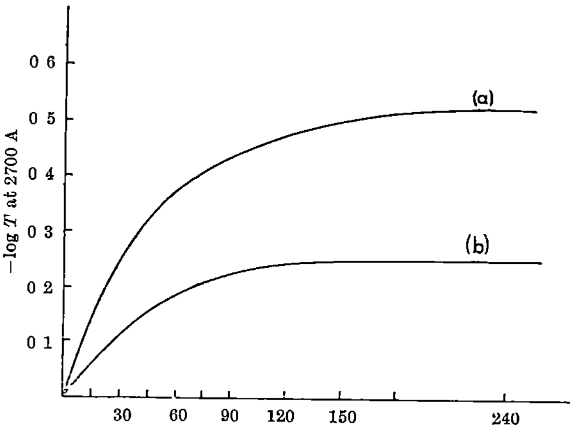


Fig 1 Rate of formation of material absorbing at 2700 A from diketopimelic acid and ammonium salt (*a*) Reaction mixture (2 ml) contained diketo acid (5 mgm), calcium carbonate (2 5 mgm), ammonium acetate (8 mgm) and heated centrifuged extract from disintegrated vegetative cells of *Bacillus cereus* (20 mgm dry wt) Control contained no diketo acid (*b*) as for (*a*) but without cell extract Control contained no ammonium acetate Samples (0 1 ml) removed at intervals after incubation at 37° C on a rotary shaker The absorption of the diluted sample (1 30) was measured in a 'Unicam' quartz spectrophotometer (*S P* 500) using the appropriate control as blank

of 0 1 M ammonium acetate solution was added and the resulting solution (pH 7 1) was incubated at 37° C for 24 hr The incubated solution was freeze-dried, which removed most of the excess ammonium acetate The product was dissolved in water (1 ml) and treated with ethanol (3 ml) The precipitate was recovered by centrifugation, dried and shaken with a small volume of 0 05 M calcium chloride solution The insoluble fraction was recovered and dissolved in the minimum volume of hot water On cooling, crystallization occurred The insoluble material was recrystallized from hot water The crystals were isolated and dried *in vacuo* at 60° C over phosphorus pentoxide Yield approximately 6 mgm Similar material was isolated from reaction mixtures containing cell extract In both cases the product was calcium dipicolinate according to the following criteria (1) appearance of the crystals , (2) extinction coefficients at 2700 and 2775 A , (3) the infra-red spectra of both products which agreed exactly with that of natural calcium dipicolinate , (4) paper chromatography using Whatman paper (No 1 or 4) and butanol/acetic acid/water (4 1 5 v/v, upper phase) as solvent The spots corresponding to the products and authentic calcium dipicolinate were visible when the dried paper was viewed with a source of ultra-violet light ('Chromalite' lamp) and had the same R_F value When the paper was sprayed with a solution containing ferrous ammonium sulphate (0 1 per cent w/v) and ascorbic acid (0 1 per cent w/v) in 0 5 M acetate buffer, pH 5 5 (ref 8), the spots turned pink

The formation of dipicolinate in the absence of oxygen uptake can only be explained in terms of an oxidation-reduction reaction occurring between the products of the reaction of diketopimelic acid with ammonia, and perhaps diketopimelic acid Identification of products other than dipicolinate has not been attempted , but paper chromatography of reaction mixtures showed that a number of compounds is produced When the effect of oxidizing agents on the reaction was studied it was found that quinone had an effect similar to that of cell extract on the rate of production and final yield of ultra-violet light absorbing product Fig 2 shows the rate of production of material absorbing at 2700 A in the presence and absence of quinone The absorbency values were affected by the formation of hydroquinone, but increased formation of dipicolinate in the presence of quinone was confirmed by paper chromatography It is possible that the oxidative system in bacterial cells acts in a similar way to quinone and the reduced system is then oxidized directly or indirectly by atmospheric oxygen

Attempts to demonstrate diketopimelic acid as a constituent of sporulating cells of *Bacillus cereus* were unsuccessful In these experiments, deproteinized cell extracts were treated with 2 4-dinitrophenylhydrazine and the keto-acid derivatives were extracted with ethyl acetate and chromatographed on paper[9] Comparison spots of the 2 4-dinitrophenylhydrazones of α-ketoglutaric, oxaloacetic, pyruvic and αε-diketopimelic acids and of acetone were run on the same paper The chromatogram showed derivatives of pyruvic acid and acetone to be present but no diketopimelic acid could be detected in 120 mgm (dry weight) of cells However, it was found that when diketopimelic acid was added to cell suspensions which were then disintegrated, treated with reagent and chromatographed, the dinitrophenylhydrazone of this keto acid could not be detected A negative result was probably due to the rapid reaction of the keto acid with endogenous ammonia when the cells were disrupted

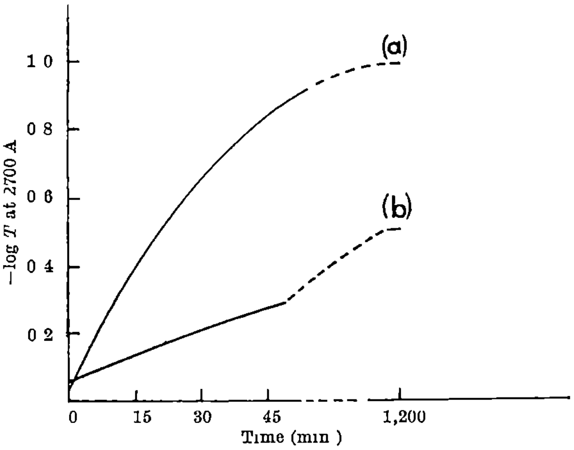

Fig 2 Effect of quinone on the formation of dipicolinic acid from diketopimelic acid and ammonium salt (*a*) Reaction mixture (1 ml) contained diketo acid (2 mgm), calcium carbonate (1 mgm), ammonium acetate (4 mgm) and quinone (0 1 ml sat aq solution) Control solution contained no diketo acid (*b*) As for (*a*) but without quinone Solutions incubated at 37° C and samples treated as in Fig 1

Attempts to implicate αε-diketopimelic acid as a precursor of αε-diaminopimelic acid in bacterial cells were unsuccessful Reaction mixtures after incubation of cell homogenate with keto acid and either ammonium chloride, glutamic acid, glutamine or aspartic acid were tested for the presence of diaminopimelic acid using the solvent system of Rhuland *et al* [10] Unheated cell homogenates were tested in these experiments and pyridoxal phosphate was added No diaminopimelic acid was detected in samples of reaction mixture initially containing 130 μgm of the keto acid

In an interesting article on the pyridine ring and the problem of its biosynthesis, Grimshaw and Marion[11] have suggested that the pyridine ring might be built directly from smaller units arising from alanine and glycine or possibly from non-nitrogenous precursors and ammonia Martin and Foster[12] have reported two possible pathways of dipicolinate synthesis in *Bacillus megaterium* involving either pyruvate and aspartate or alanine and oxaloacetate The experiments reported here are of interest in this connexion, and we consider that even though diketopimelic acid has not been demonstrated as a cell constituent, its reactions with ammonia in the presence and absence of cell extract suggest some interesting possibilities

We wish to thank Mr S Lovett for synthesizing αε-diketopimelic acid and Dr K P Norris for infra-red spectrophotometry We are grateful to Dr D H Herbert, Mr E O Powell and Major L H Kent for useful suggestions and discussion

HIGH-RESOLUTION FIBRE OPTICS USING SUB-MICRON MULTIPLE FIBRES

By Dr. N. S. KAPANY

Optics Section, Physics Division, Armour Research Foundation, Chicago 16, Illinois

In various image transmitting applications of fibre optics[1,2] using the light conduction property of fibres because of total internal reflexions, it is desired that the fibres have a high light transmission, complete optical insulation and diameter as small as possible. The information density in a perfectly insulated fibre bundle is dependent only on the fibre diameter, which has been limited by mechanical properties of the fibres and the basic diffraction phenomenon. This latter limitation, due to diffraction, has not been investigated in the past[3,4], and it had been believed that only fibres larger than 10–20 wave-lengths in diameter are capable of conducting energy. For smaller diameters, it was believed that the energy escapes from the fibre wall due to the diffracted wave striking at angles less than critical incidence.

This is found not to be true for circular cross-section straight fibres down to approximately two wave-lengths in diameter. Fibres as small as 0·75 μ in diameter have been drawn using the newly developed technique of 'multiple fibres', and found to give acceptable light transmission. Whereas diffraction effects occur for fibres of smaller diameter, it has been found that the effective numerical aperture of the emergent diffracted light cone from a straight fibre of diameter greater than two wave-lengths of light is not substantially in excess of the numerical aperture of the lens system required to resolve clearly the fibres at the image pickup end. On the other hand, all the emergent flux is received when a photodetector or photographic plate is placed in contact with the emergent end. Thus high resolution, as well as high light efficiency, is achievable using the more recent techniques in fibre optics.

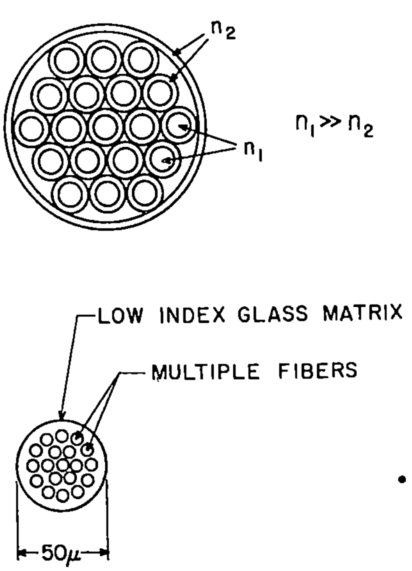

Fig. 1 Illustrating the method of drawing multiple fibres

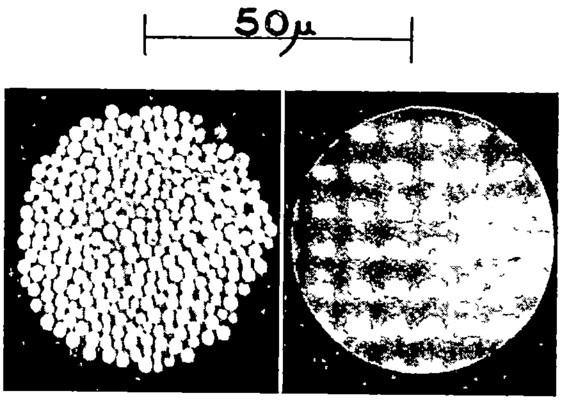

Multiple fibre Dynamic image

Fig 2 Photomicrograph of grid object through a 50μ overall diameter multiple fibre consisting of approximately 275 fibres of 2·5μ average diameter

A method for drawing high refractive index fibres coated with a glass of low refractive index consists, essentially, of placing a high-index rod in a low-index tube and pulling the assembly down to a fibre on a continuously rotating drum[5]. Fibres down to 25μ diameter with a coating thickness of 0·5–1μ have been drawn in nominal infinite lengths. In addition to optically insulating the fibre, the coating, also, eliminates surface absorption or scattering losses. A 7-ft.-long glass-coated glass fibre is found to transmit an average of 20 per cent in the visible spectrum and nearly 50 per cent in the yellow-green region. However, such fibres become very difficult to handle mechanically in diameters much smaller than 25μ.

A new type of 'multiple fibre' consisting of a large number of fibres of high refractive index in an insulating matrix of low refractive index has been developed. They have the mechanical strength of large fibres and resolution yield of much smaller fibres. Fig. 1 shows a method for drawing multiple fibres. A large number of high refractive index rods are inserted in low refractive index tubes and the entire bundle is placed in a larger tube of compatible glass. This unit is then drawn into a fibre on a continuously rotating drum. The cross-section of resultant fibres is also illustrated in Fig. 1. The ratio of the parent rod to tube thickness, etc., is maintained in the fibre form. Multiple fibres down to 50μ overall diameter, consisting of as many as 275 fibres of approximately 2·5μ diameter, have been drawn by this method. A high-information density is thus achievable. The mechanical advantages of manipulating and fusing fibres down to a few microns in diameter by this technique are obvious.

Fig. 2 shows a multiple fibre of overall diameter 50μ, with average fibre diameter of 2·5μ. A dynamic picture of a grid test object through this multiple fibre is also shown in Fig. 2. Limiting static resolution of up to 200 lines/mm. has been measured in such an assembly of multiple fibres. As is indicated by further diffraction studies, the resolution obtained thus far is not the upper limit for the fibre optical systems

In order to study the optical properties and diffraction effects in smaller fibres, multiple fibres ranging between 0 75 and 20μ in diameter have been drawn This was achieved simply by choosing parent rods and tubes of different diameters A multiple fibre was placed on a microscope in which both the numerical apertures of the condenser and the objective could be varied along with the wave-length of light Fig 3 illustrates this apparatus diagrammatically The image of the multiple fibre is formed on a photodetector for the purposes of photometry of fibres of various diameters Interference filters were introduced in the path; thus different ratios of wave-length of light to fibre diameter are obtained From elementary considerations, it is clear that due to the diffraction by the fibres, as the objective N A is decreased, the photodetector would receive less flux per unit area from fibres of smaller diameters

Multiple fibres ranging from 0 75μ to 8μ diameter, 0 2 in long, were thus studied on the above-mentioned system Two wave-lengths peaked at 386 mμ and 663 mμ with half band-width of 125 A were used The condenser numerical aperture was varied from 0 4 to 0 8 and the objective N A was varied from 0 3 to 1 33 Within this range of N A and wave-lengths, for fibres above 0 75μ diameter, no measurable difference in flux density was observed For smaller N A of the objective, however, one might expect the effects to show up On the other hand, for such small objective N A the fibres fall close to the resolution limit of the system used for image pickup Fig 4 shows various diameter multiple fibres that were examined in this manner and a 0 75μ diameter fibre is indicated by an arrow In Fig 4*a*, it should be noticed that some fibre separations are of the order of one wave-length, which is the desired thickness, in order to prevent light leakage between neighbouring fibres ($d > \lambda$) due to frustrated total reflexion[5] Very small quantities of light were observed between adjacent fibres This is attributable primarily to the diffraction effects in the microscope objective and perhaps to a lesser degree to light scattering by the low-index medium that may experience large amounts of stress In Fig 4*b* the fibre separation is not observable because the low-index coating falls near the threshold of limiting resolution of the 0 65 N A objective The optical insulation of these fibres was also tested by forming the image of a knife edge and observing the intensity gradient in the transmitted image

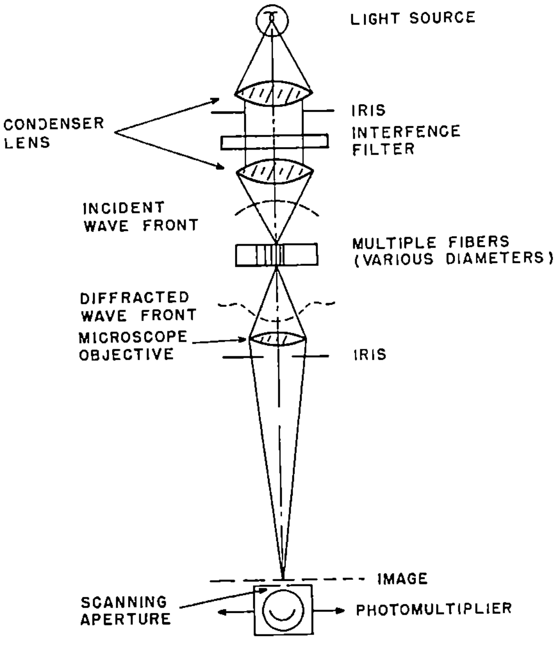

Fig 3 Illustrating the optical system for studying the flux density in the diffracted wave by multiple fibres of various diameters

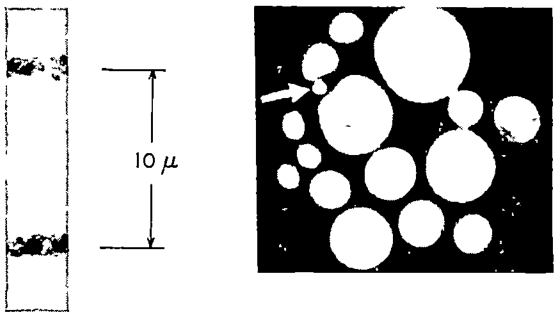
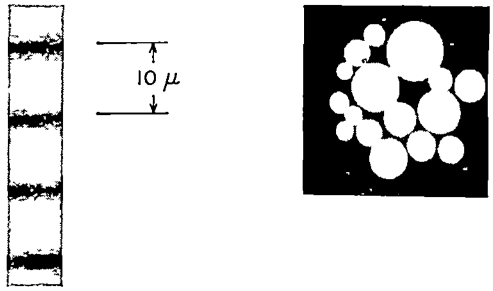


$(N\,A)_{OBJ} = 1\ 3$ WHITE LIGHT

$(N\,A)_C = 0\ 8$ (a)



$(N\,A)_{OBJ} = 0\ 65$ $\lambda = 663\ m\mu$

$(N\,A)_C = 0\ 8$ (b)

Fig 4 Photomicrograph of variable diameter multiple fibres (0 75–8μ diameter) obtained on the optical arrangement in Fig 3 A 0 75μ diameter fibre is pointed out by the arrow

From the results of these experiments, and basic theoretical studies, the following conclusions are derived To a first approximation, the diffraction in straight circular fibres above two wave-lengths in diameter occur primarily at the two ends The incoherent wave incident on a fibre suffers diffraction at the entrance dielectric aperture The diffracted wave then suffers total reflexions and phase changes along its passage in the fibre until it arrives at the emergent end, where it suffers diffraction again This, of course, assumes that the refractive index of the fibre core and surround is such that the critical angle conditions for the wave in the fibre are satisfied It is clear that for a plane monochromatic incident wave, as the diameter of the fibre decreases, so the emergent diffracted cone angle increases On the other hand, as the fibre diameter goes down, so the required N A of the optical system receiving the image from the fibres goes up, in order that full use is made of the smaller diameter fibre resolution. For smaller fibres ($d > \lambda$) the limiting resolution of the optical system is set by the fibre coating ($\simeq \lambda$) Thus, most of the energy emerging from fibres down to 1μ in diameter is received by the appropriate N.A optical system These conclusions are also substantiated by a parallel study using microwave analogues of fibre optics at 1 25 cm wave-length and polystyrene cylinders Theoretical and experimental studies of diffraction by fibres smaller than the wave-length and the boundary wave skin effect are now in progress

From the foregoing it is evident that the optical performance of fibres down to a few microns in diameter do not suffer due to diffraction effects An appropriate assembly of 1μ diameter fibres is capable of a static resolution of 500 lines/mm and dynamic resolution of nearly 1,000 lines/mm Fibre optics in the ultra-violet region are capable of even higher resolution Multiple fibres have rendered such fibre optical systems practical The impact of these investigations on such applications of fibre optics as flexible endoscopes, field flattener and image transfer from Lambertian emitters is evident These results are also relevant to some basic studies of the visual mechanism in the retinal rods and cones

PALÆOMAGNETIC STUDIES OF CENOZOIC VOLCANIC ROCKS IN NEW ZEALAND

By DR. D. S. COOMBS
Geology Department, University of Otago

AND

DR T. HATHERTON
Geophysics Division, Department of Scientific and Industrial Research, Wellington, New Zealand

POSTULATED reversals of the geomagnetic field[1] offer a potential tool for the chronological subdivision and correlation of lavas within a restricted volcanic province[2–4] On a broader scale they provide potential world-wide datum planes of virtually instantaneous time significance so far as most geological processes are concerned. For reversals to be useful for long-range correlations, not only must their reality be established, but also the length of time between reversals must not be too small in comparison with the time duration of stratigraphically separable stages An early Pleistocene reversal as postulated by Roche[5], Hospers[6], Einarsson[4] and others should prove to be of considerable importance in Pleistocene chronology if it is established that only one such simultaneous reversal occurred during Pleistocene time On the other hand, it may be much more difficult to establish contemporaneity of early- or pre-Tertiary reversals Detailed study of many well-dated suites will be required to demonstrate whether long-range correlation of reversals can be effected, and if so, to determine the date at which each reversal occurred Data from some New Zealand rocks are here recorded as a contribution towards the solution of these problems Correlations of New Zealand stages follow the table of Hornibrook[8]

1 *Pleistocene* Ignimbrite sheets of the Whakamaru district, North Island, New Zealand, are normally magnetized[9] According to J Healy (personal communication), they probably belong to the Hawera or late Castlecliffian stage (Upper Pleistocene) Tholeiitic basalt at Timaru overlying gravels of the Waitotaran (Upper Pliocene) to Nukumaruan (Lower Pleistocene) and possibly itself of Nukumaruan age (Gair, H S , personal communication) is found to have reverse magnetization (north pole directed downwards, dip 75°, declination 228°)

2 *Late Middle to Upper Miocene* The directions of magnetization have been measured of more than fifty suites of rocks from the Dunedin Volcanic Complex, which has been divided[10] into an Initial, and First, Second and Third Major Eruptive Phases Each suite consisted of 3–8 (usually 5–6) specimens collected where possible over some tens of yards of exposures in road cuts, quarries and cliff sides Results from exposed, craggy outcrops are not here considered. Collections were made from sequences of flows in localities scattered over an area of about 12 × 15 miles The results from each suite have been treated by Fisher's method to obtain the mean directions which are shown in the figures

Basalts, kaiwekite, phonolites, atlantite and trachyandesites from the First and earlier parts of the Second Major Eruptive Phase all indicate essentially normal magnetization (Fig 1) In contrast, all flows sampled from the upper part of the middle sub-phase (2 *M*) and the late sub-phase (2 *L*) of the Second Major Eruptive Phase (above flow 21 of the North Head sequence[12]) show reverse or anomalous directions of magnetization (Fig 2) Basalts, trachyandesites and phonolites are plotted, the basalts being the most consistent Dotted lines join points representing mean directions of magnetization calculated from two localities in the one

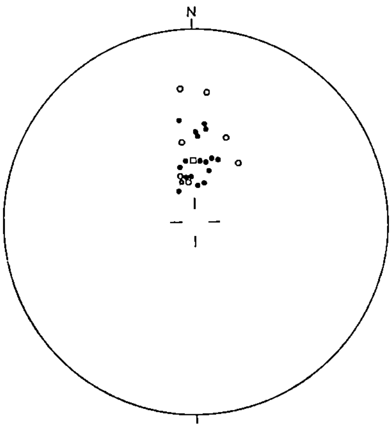

Fig 1 Directions of magnetization for lavas of First and earlier parts of Second Major Eruptive Phase Dunedin district, plotted on equal area projection ●, North pole directed upwards, radius of circle of confidence, 5 per cent level, < 12° , ○, north pole directed upwards, radius of circle of confidence, 5 per cent level, 12–15° , □, direction for symmetrical axial dipole field, latitude 46° S

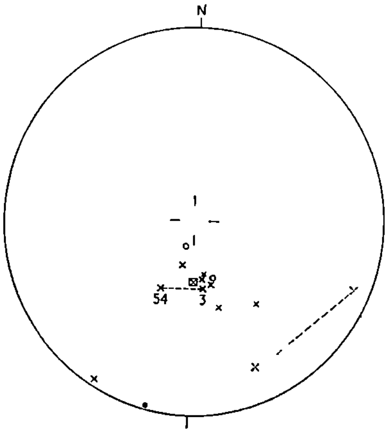

Fig 2 Directions of magnetization for lavas of the upper-middle and late sub-phases of the Second Major Eruptive Phase, Dunedin district **X**, North pole directed downwards, radius of circle of confidence, 5 per cent level, < 12°, ×, north pole directed downwards, radius of circle of confidence, 5 per cent level, 12–20°, X, north pole directed downwards, radius of circle of confidence, 5 per cent level, > 20°, ●, north pole directed upwards, radius of circle of confidence, 5 per cent level, < 12°, ○, north pole directed upwards, radius of circle of confidence, 12–20° ☐, direction for reversed symmetrical axial dipole field, latitude 46° S

flow (for example, Roslyn doleritic basalt, 3 and 54) The Leith Valley trachyandesite and some similar flows of this period are weakly and erratically magnetized in directions which are consistent only in that they are abnormal These have not been plotted We can detect no consistent trend with time for these abnormal directions, and instability is possible, although 'magnetic cleaning' experiments of several types have failed to make them significantly more consistent. Three basalts and two weakly magnetized phonolites of the Third Major Eruptive Phase give normal directions while two other weakly magnetized phonolites correlated with the same period show anomalous declinations (Fig 3)

There is thus a fairly clear sequence normal—reverse (plus anomalous)—normal in this petrographically diverse volcanic complex The age of the earlier First Phase volcanics has been established[11] as later Waiauan (latest Middle Miocene) or possibly early Tongaporutuan (earliest Upper Miocene) The upper age limit is not clear although activity probably did not extend far into the Pliocene If the hypothesis of world-wide contemporaneity of reversals is accepted, a plausible correlation of the reverse period would be with the Upper Miocene–Lower Pliocene (Pontian–basal Plaisancian) reversal reported in France[3,5], but the possibility that it represents an earlier reversal within Upper Miocene time cannot at present be eliminated

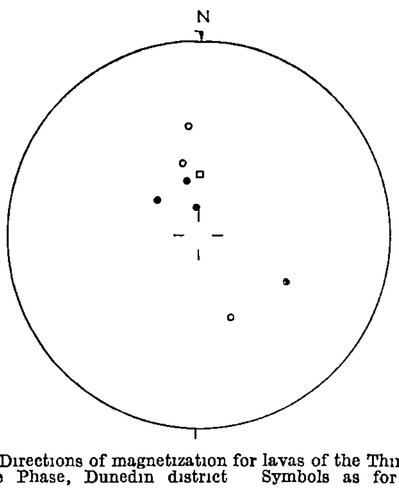

Fig 3 Directions of magnetization for lavas of the Third Major Eruptive Phase, Dunedin district Symbols as for Fig 1

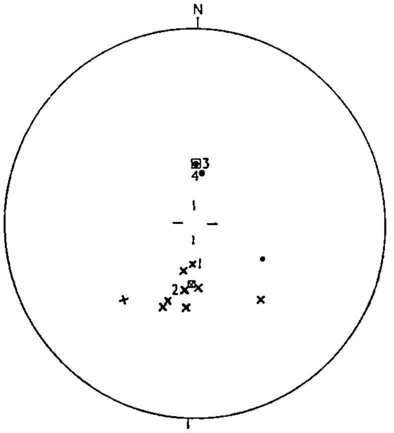

Fig 4 Directions of magnetization for Upper Eocene–Lower Oligocene volcanics of north-east Otago Symbols as for Figs 1 and 2

3. *Eocene–Lowermost Oligocene* Pillow lava (1), and a dolerite sheet (2) at Oamaru, North Otago, together with a series of dykes and other intrusions of dolerite at Moeraki Peninsula, show reverse magnetization The results plotted (Fig 4) have been corrected for post-consolidational tilting The pillow lava occurs above tuffs correlated with the Kaiatan stage and immediately below tuffs and tuffaceous limestone bands with microfaunas of Kaiatan or Runangan age, that is, earlier or later Upper Eocene (Hornibrook, N de B, and Marwick, J, personal communication) The Moeraki rocks are also placed in the Kaiatan or Runangan stages on microfaunal evidence (Scott, G. H, personal communication), whereas the Oamaru sheet is Whaingaroan (earlier Lower Oligocene)[13] A dyke (3) and sheet (4) at Enfield, North Otago, of approximately the same age have normal magnetization

An Upper Eocene period of reversal is indicated The evidence does not show whether this continued through to Lower Oligocene times, or whether one or more periods of normal magnetization intervened The North Otago results are also of interest in that, together with the later Tertiary and Pleistocene results, they do not suggest any measurable polar wandering with respect to New Zealand since Late Eocene times

We are grateful for the assistance of a number of colleagues Dr A J R White has given much help in the field, and a grant to one of us (D S C) from the University of New Zealand Research Fund is gratefully acknowledged

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, November 9

Institution of Electrical Engineers, Electronics and Communications Section (at Savoy Place, London, W C.2), at 5 30 p m —Prof A L Cullen "Theory of the Travelling-Wave Parametric Amplifier", Dr P J B Clarricoats "The Gain of Travelling-Wave Ferromagnetic Amplifiers", Mr A Jurkus and Mr P N Robson "Saturation Effects in a Travelling-Wave Parametric Amplifier"

Royal Geographical Society (at 1 Kensington Gore, London, S W 7), at 8 30 p m —Mr A J Marshall "Pearl and Cattle Country of the Kimberleys"

Tuesday, November 10

Institute of Physics (at 47 Belgrave Square, London, S W 1), at 5 30 p m —Dr F G Champion "Electronic Properties of Diamonds"

Illuminating Engineering Society (at the Federation of British Industries, Tothill Street, London, S W 1), at 6 p m —Mr A H McKeag "Research in Phosphors"

Wednesday, November 11

Institution of Gas Engineers, British Coke Research Association, and the Coke Oven Managers' Association (in the Lecture Theatre of the Institution of Civil Engineers, Great George Street, London S W 1), at 2 30 p m —Mr G W Lee "The First Year of the Coke Research Centre"

Institution of Mechanical Engineers, Lubrication Group (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Mr A D Newman "Extreme Pressure Lubricants for Marine Gears"

British Institution of Radio Engineers (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 6 30 p m —Dr R P Gannon "Physiological and Acoustical Aspects of Hearing"

Oil and Colour Chemists' Association, London Section (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W 1), at 7 p m —Mr R R Davidson "Whiting Dispersions, Particle Packing and Surface Adsorption"

Thursday, November 12

Institute of Metals, Metal Physics Committee (at the Royal Institution, 21 Albemarle Street, London, W 1), at 9 30 a m.—Symposium on "The Application of Thin-Film Techniques to the Electron-microscopic Examination of Metals"

University of London (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 1 15 p m —Dr E H S Burhop "Transient Forms of Matter" *

Royal Society (at Burlington House, Piccadilly, London, W 1), at 4 30 p m —Mr J Davis, Mr J S Greenhow and Mr J E Hall "Combined Photographic and Radio Echo Observations of Meteors", and "The Effect of Attachment on Radio Echo Observations of Meteors"

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1) at 5 30 p m —Dr M H F Wilkins "The Molecular Structure of Chromosomes" * (Ninth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation Further lectures on November 17, 19, December 1, 3, 8, 10)

Society of Chemical Industry, Heavy Organic Chemicals Group (at 14 Belgrave Square, London, S W 1), at 6 p m —Mr D G Smith "The Production of Bulk Organic Chemicals" (Inaugural Lecture)

Textile Institute (joint meeting with the Clothing Institute, at the British Colour Council, 13 Portman Square, London, W.1), at 6 45 p m —Mr J David, Dr T H Morton and Mr W Garner "Looking Ahead in the Clothing Industry"

Friday, November 13—Saturday, November 14

Institute of Physics, X-Ray Analysis Group (at the Institution of Civil Engineers, Great George Street, London, S W 1), at 10 a m on Friday and 9 30 a m on Saturday—Autumn Conference—"Structure Analysis and Experimental Techniques"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Assistant Lecturer or Lecturer in Mechanical Engineering —The Registrar, University College, Singleton Park, Swansea (November 7)

Head of the Department of Applied Physics, Head of the Department of Mathematics, Head of the Department of Aeronautical Engineering, Head of the Department of Building and Civil Engineering—The Registrar, Lanchester College of Technology, Coventry (November 9)

Senior Lecturer or Lecturer (with a good honours degree and relevant teaching experience) in Mathematics at the Nigerian College of Arts, Science and Technology—The Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W C 2 (November 13)

Research Officer (with a degree in horticulture, agriculture or economics, and preferably a knowledge of horticulture or farm crop production), to carry out investigations into the economics of horticulture—The Secretary, School of Agriculture, The University, Cambridge (November 18)

Lecturer (with good academic qualifications and experience in the field of electric power engineering, preferably electrical machines) in the Department of Electrical Engineering—The Registrar, The University, Leeds 2 (November 20)

Research Officer (honours graduate in engineering or science (or equivalent), with postgraduate experience in the design of radio and electronic equipment) in the Division of Radiophysics, Commonwealth Scientific and Industrial Research Association, Sydney, N S W, Australia, to lead the research of a small group responsible for development and application of new electronics and radio-frequency techniques, particularly in U H F and microwave receivers for use in radio astronomy observations—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W C 2, quoting Appointment No 780/199 (November 20)

Senior Lecturer, Lecturer, and an Assistant Lecturer in the Department of Electrical Engineering—The Registrar, Royal Technical College, Salford (November 21)

Assistant Librarian in the Philosophical Library—The Secretary, Philosophical Library Committee, The University, Free School Lane, Cambridge, marking envelope "Application" (November 23)

Lecturers (2) in Psychology at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, November 30)

Plant Breeder (with at least a B Sc degree in agriculture or botany and experience in plant breeding or genetics) in the Section of Plant Breeding and Genetics, for duties involving the breeding and selection of sugar-cane varieties—The Director, Mauritius Sugar Industry Research Institute, Réduit, Mauritius (November 30)

Senior Research Officer and a Research Officer (qualified zoologists with experience of fisheries research) in the Department of Zoology, University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Hong Kong, November 30)

Research Fellow (with at last two years research experience, and preferably experience in high vacuum techniques or in solid state chemistry) in the Chemistry Department, for the study of fundamental processes occurring between lead and reactive gases—The Registrar, University of Melbourne, Carlton, Victoria, Australia (December 4)

Professor of Applied Mathematics at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1, or The Registrar, University of Queensland, Brisbane, Queensland, Australia (Australia and London, December 15)

Senior Lecturer in Anthropology at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, December 15)

Waynflete Professor of Physiology—The Registrar, University Registry, Oxford (December 17)

Tucker–Price Fellow for Research in Mathematics, Natural Sciences, or an allied subject and a Rosalind Lady Carlisle Fellow, for research in any other branch of learning—The Secretary, Girton College, Cambridge (January 15)

Fisheries Officer (with a university degree in biology with emphasis on zoology, and experience of fisheries work) in the Northern Region of Nigeria for development of river fisheries and the demonstration and organization of peasant fish culture—The Director of Recruitment, Colonial Office, London, S W 1, quoting BCD 65/408/01/T

NATURE AND THE RECENT PRINTING DISPUTE

THE printing dispute which for about six weeks held up much printing and publishing in Britain is now happily over. Unfortunately, during that period it was not possible to publish *Nature*; nevertheless, contributions continued to be submitted from all parts of the world at the usual rate and volume. This meant that the Editors were able to function and face their normal duties during the dispute; but abnormal problems arose afterwards.

Now that the dispute has been resolved, type-setters, block-makers, printers and publishers throughout the country are finding themselves tied by commitments and inundated with requests. *Nature's* problem is not only to catch up as quickly as possible but also to accommodate the many contributions which have been accepted before, during and since the strike. Goodwill is prevailing among all those concerned with producing the journal, and a spirit of understanding emanates from the scientists themselves. These the Editors gratefully acknowledge.

However, in spite of all efforts being made by the printers, who have been so completely and competently in charge of the production of *Nature* for the past well-nigh thirty years, it has proved desirable to invoke the aid of other type-setters and printers, especially if the immediate aim is to be dual-purpose, that is, come up to date quickly but not at the cost of volume of work published. Again we are happy to record that everyone connected with this move and the extension of activities is co-operating closely. Nevertheless, such a project, involving as it does the transfer of some manuscripts not set, some type of those partially or completely set and the selecting of when and where these are to be sent for finishing and collating, is proving to be a heavy burden, especially on the Editors. Yet this work is being carried out successfully and in good heart; and it is to be hoped that full issues of *Nature* will soon be appearing on their appropriate dates.

Nevertheless, so complicated is this work that whereas some communications are delayed, others are being published more quickly than is normal. No doubt the authors who are suffering the longest delay are those whose manuscripts were only partially ready for printing when the dispute began. The Editors regret that in such cases they had no choice in the matter, and nobody can be blamed for this temporary set-back.

As readers of *Nature* will have noted, the present modifications of normal procedure have resulted in each issue being published in two parts—the "Letters to the Editors" appearing as a supplement.

Although this will help to expedite the publication of letters, and ease the strain on the rest of the journal, and although this will soon mean that even more communications than hitherto can be published, now is an appropriate time for enlisting the assistance of contributors and indicating how they can help—though it should be stressed that the following comments apply to any journal at any time.

When referring to the preparation of manuscripts for press, in a lecture delivered before the Royal Society of Edinburgh some years ago, Mr. L. J. F. Brimble suggested that a would-be author should ask himself the three following questions before mailing his manuscript: (1) Have I said what I really mean? (2) Have I said it in the minimum number of words? (3) Is it necessary to say it at all? The fact that this was quoted in at least eighty journals throughout the world and afterwards personally reiterated by other editors indicates that authors might well ponder such queries for the sake of themselves, their readers and their editors.

By and large, an editor reserves the right to assist an author in deciding the answer to the third question, at any rate so far as his own journal is concerned; yet, even if acceptable, articles and other communications could often be much improved before submission for publication, and for this the author and/or his advisers are entirely responsible. For example, corrections in proof are exacting for a type-setter, time-consuming for him and the printer, costly to the publisher (and in the case of some journals to the author himself) and frequently irritating to the editor, especially when the last-named knows full well that more careful preparation of the manuscript in its initial stages would have rendered many such corrections unnecessary. In the case of *Nature*, costs of corrections are borne by the publishers.

There are authors who still rush their manuscripts to an editor knowing that they have not yet said the last word on the subject, but who aim at correcting and improving (?) in proof. Recently, for example, the manuscript of a communication to *Nature* contained the following numerical values: 7·28 ± 0·82, 8·92 ± 1·09 , these were changed to 11·15 ± 1·30, 5·12 ± 0·85 in the proof.

Although in general authors are reasonable with their corrections, there are those contributors whose corrections cost more than the original setting. Perhaps the most expensive author is he who does not hesitate to make changes on the proof of an illustration which he himself had originally prepared, apparently assuming that such changes are possible. Actually, except in the case of very minor alterations, a new block has to be made, which may cost several pounds sterling.

Another problem which must now be facing all editors of scientific journals and certainly most readers of such journals is that of abbreviations. Obviously, many of these, symbols, etc., are essential to such an exact discipline as science; but among a high percentage of scientists to-day the devising of abbreviations seems to have developed into a cult. Often the straightforward full word is all that is needed; but even more important in any journal which covers all branches of science, it must be borne in mind that an abbreviation often has more than one meaning, especially between one subject and another. For example, a geologist recently submitted a communication containing the letters B.C. to mean Boulder Clay. To most biochemists PAS means periodic acid-Schiff; but to others it may mean *para*-amino-salicylic acid. The symbol H has been adopted by some to indicate histamine; but for a very long time to all scientists it has been the symbol for hydrogen. One author expected the editors to use the expression cytidylic acid-U-C^{14} to mean "uniformly labelled cytidylic acid with respect to carbon atoms contained therein". To a few authors the letters D.C.L. stand for Distillers Co., Ltd., whereas in the much wider field of academics these have a quite different connotation. Some physiologists indicate cardiac output by the abbreviation CO which might well confuse others. One author who wrote M.I.T. to mean monoiodotyrosine had apparently not heard of the Massachusetts Institute of Technology.

There is no doubt that many abbreviations are essential for they can be so exact; but there are certainly a number of authors who apparently imagine that their articles appear more 'scientific' if these are peppered with abbreviations. Although the Editors of *Nature* are now well versed in abbreviations adopted by scientific writers, such is the present height of this Tower of Babel that the former sometimes have to refer a communication back to an author asking what he means. This is, to say the least of it, a waste of time. Recently a communication received had anything from one to three abbreviations in each line (some obviously made up by the author himself). The communication defied interpretation; yet after the author had been shown the error of his ways, the revised manuscript, without a single abbreviation, revealed an elegant and interesting piece of research work. But before that communication could be published it had to pass backwards and forwards three times half-way around the world.

It is not irrelevant to point out now that, despite many efforts at achieving standardization in scientific presentation, journals vary considerably, though each one endeavours to be consistent within itself. It would save much time and, indeed, be a courtesy to any editor, if an author consulted beforehand the journal to which he proposes submitting his manuscript. He would certainly obviate the risk of errors. For example, *Nature* endeavours to be consistent in the way footnote references are inserted; yet frequently authors adopt their own methods (or those of other journals), and these, sometimes being quite different from *Nature's* custom, involve extra work on the part of the Editors and the risk of wrong quotations or citations.

Perhaps the most problematical of all authors is he who wishes to withdraw his communication after it has been submitted. The timing of such withdrawal is often very awkward. If the author withdraws at about the same time as the editor decides to reject then little harm has been done. But if the author withdraws, as he sometimes does, after the communication has been set in type, then considerable costs have been incurred and the time of editors, type-setters (and sometimes even block-makers and printers) has been wasted. Moreover, if the request to withdraw comes after the contribution has reached page-proof stage, then really difficult editorial and printing problems arise. An author is therefore well advised to ponder his communication after he has written it, and scrutinize fully the possible consequences to himself and the readers of his communication, before submitting it to any journal; for there is the ultimate risk, which sometimes occurs, that it is too late to withdraw the publication, anyhow.

The foregoing suggestions and observations should be considered carefully by all likely contributors to the columns of *Nature*, for they apply at any time, though never so urgently as at present. It is to be hoped that all authors and readers will recognize the inevitability of a certain amount of delay during this period of getting back to normal; though we have already reached the stage when genuinely urgent material can be dealt with promptly. The time is not far off now when *Nature* will again be on an even keel so far as date of publication is concerned, and equally as soon it is hoped that even more text than hitherto can be accommodated.

The Editors gratefully acknowledge the assistance given and co-operation shown by all type-setters, block-makers, printers and publishers during what has turned out to be the most exacting period in *Nature's* history; and everyone concerned with the production of the journal has been encouraged by the sympathetic understanding shown by scientists the world over.

FORTY-SEVEN AUTHORS IN SEARCH OF A CONCLUSION

Virus Growth and Variation

Ninth Symposium of the Society for General Microbiology held at the Senate House, University of London, April 1959. Edited by A. Isaacs and B. W. Lacey. Pp. viii+272. (Cambridge: At the University Press, 1959. Published for the Society for General Microbiology.) 35s. net.

Perspectives in Virology

A Symposium. Edited by Morris Pollard. Pp. xix+312+2 plates. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1959. Published for the Institute of Microbiology, Rutgers University.) 56s. net.

Advances in Virus Research

Vol. 6. Edited by Kenneth M. Smith and Max A. Lauffer. Pp. viii+382. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1959.) 10 dollars.

THE most integrated of these three volumes is the collection of essays on virus multiplication that the Society for General Microbiology expected those attending the symposium, that it arranged in April, to have bought and read before the meeting.

There is now fairly general agreement with the opinion, stressed by some when the same symposium was held in 1952, that virus multiplication cannot usefully be compared to the growth of a micro-organism on an inert medium. Rather, it is the exploitation and diversion of the pre-existing synthetic capacities of the host cell. One product of this anomalous metabolism is material that resembles the intruder. It is, however, clear from the papers by Harrison and Hoskins that the host has definite synthetic preferences. Not only is there the well-known insusceptibility of most organisms to most viruses, but there are many examples of variation induced by the host. Virus infection is a general metabolic derangement, and the derangement often precedes any apparent virus multiplication.

Luria, Kellenberger and Hirst stress the analogy between genetic processes and virus multiplication. It may well be that this is more than an analogy and that there is substance in Muller's suggestion in 1922 that viruses could be likened to free genes. Some writers, though not those quoted, have followed the analogy blindly and made it seem ridiculous. Put in sober biochemical terms, it amounts to the proposition that, among the mechanisms deranged, are those normally concerned with the production of whatever it is that genes are made of and of the nucleoproteins of chromosomes. Enthusiasts will find that a colourless way to put the matter, but this may serve to bring out the diversity of the problem. There was a time when some biochemists announced resoundingly that they were studying 'oxidations' or even 'enzyme actions'; we now have the sense to state the substrate and tissue actually used. So, too, with viruses. Different viruses in the same host interfere with different processes and the normal processes most commonly deranged vary from host to host. This book makes it abundantly clear that there is no one answer to the question, "How do viruses multiply"?

"Perspectives in Virology" is less integrated. It contains a charming essay by Dubos on the breaking of tulips; he realizes that a perspective can point in any direction. On the historical framework of the part played by this virus infection in promoting the spread of tulips around the world, he discusses the irrationality of the criteria by which we commonly distinguish symbionts from pathogens. The puzzling relations between pigs, earthworms, lungworms and the hog cholera virus are clearly and thoughtfully set out by Shope. Almost half the symposium is devoted to tumour causation. Kilham discusses transformations and points out that many effects are as likely to be the result of the failure of a restraint as of the appearance of a new capacity. Beard deals with current work on viruses as a cause of cancer. This is a sensible article marred by the isolationist syndrome that often makes American scientists concentrate on work done in their own country. Its historical perspective is also limited; thus Gye does not appear among the 114 references. Fashions in science are cyclical, so that one advantage of a knowledge of the older literature is that it gives one an up-to-date, or even advance, perspective on contemporary controversy. The names change but the issues remain much the same.

The papers making up this symposium were apparently presented in February 1958, and the discussion that followed is printed though some of it is rather slight. Verbatim treatment has, however, the immense advantage that it preserves several of Peyton Rous's reminiscences and anecdotes, and these might well have been shorn from a strictly edited version.

"Advances in Virus Research" appears annually and is, naturally, without unity. A third of this issue is devoted to a review by Sonneborn on kappa and related factors in *Paramecium*; it is comprehensive and includes a valuable survey of similar bodies found in other protozoa and in insects, and a discussion of the reasons for looking on a particle as large as kappa as a virus. In the course of this he discusses the limits of the category 'virus' and this is probably the main reason for including the essay in the volume. But it would have made an excellent 127-page book on its own. Two articles deal with the purification procedures used for plant and poliomyelitis viruses. It is useful to have all these methods collected together, but it may be that the authors under-rate the extent to which differences in the precise state of the host tissue, normally used in different laboratories, will affect the way in which these methods work in practice. Consideration is also given to the inactivation of polio virus for use as a vaccine; here it is puzzling to find attention concentrated on formaldehyde. There are many other potentially useful inactivating agents with more systematic and predictable behaviour. There are lucid articles by Brenner on phage genetics and by Broadbent and Martini on the spread of plant viruses. The latter give so many examples of transmission through seeds that we can no longer regard this as unusual.

A review of thirty-six articles is necessarily selective; a list of titles and authors alone would nearly have filled the space allowed. In general, the standard is high and it is by no means a bad thing that widely different audiences are aimed at. One wonders, however, whether such ephemeral material needs to appear with so expensive a format. The total cost of these three volumes is £8. N. W. PIRIE

FROM AXES TO ATOMS

Man the Maker

A History of Technology and Engineering. By Prof. R. J. Forbes. Pp. xvi+365+41 plates. (London: Constable and Co., Ltd., 1958.) 30s. net.

"MAN the Maker" is certainly the most flattering image of him. For whatever else may be dubious in man's relatively brief history, there is no doubt that his capacity to make (or, rather, construct for man creates nothing) has steadily increased. Beginning with no more than the power to chip and hack, endowed with an instinctive dexterity less than that of some insects, he has acquired tool after tool and mastered process after process, until he can rearrange to accord with (at least partially) predetermined patterns all the component parts of the universe within his range, from the particles of the nucleus to millions of tons of rock and water. The growth of man's power, as Prof. Forbes tells it, is the strongest confirmation of progress that history can offer. It is a story without retrogressions, without Dark Ages. Further, he is right to insist that this growing power has been used for constructive purposes, unless we would limit men to the status of feeble parasites. As the first men took flesh from animals and branches from trees, their successors have gone on to pillage the Earth and poison the air on a scale ever proportionate to their growing power, for they could not build without materials nor beautify without making ugliness. But build they did and as a result human life has become ever more secure and comfortable and its focus has moved from the stomach to the brain.

The history of technology divides into two essentially different overlapping phases. The first is the development of craftsmanship, the limit of which is whatever is best of its kind, though not necessarily for its function. Some stone axes are perfect examples of craftsmanship, but a Woolworth's one is a better tool. The second is the transfer of craftsmanship to the machine and the factory, the production of which has no limit in whatever is good or bad. Once man had learnt to hunt and grow, to carpenter, smelt, and weave, as he had by about 2,000 B.C., the early history of techniques is largely concerned with the development of the fine crafts of the potter, silversmith, silk-weaver and dyer. Such artisans possessed the most advanced skills. Under successive empires from the Egyptian to the Holy Roman they supplied their masters with beauty and luxury while the life of the peasant masses continued essentially unchanged, equally ungraced by the pottery of Corinth or Deruta, by the steel of Noricum or Toledo, by the linen of Pharaohs or the scarlet of kings. So far as the majority of humanity was aware of the finest works of ingenuity in machines, in architecture, in weapons or in pageantry, it was aware of them as arousing superstitious wonder or deferential awe. Until some 500 years ago technological progress, the use of metals and of bright colours, the building of clean, solid houses, the availability of transport and of variety of food, diffused downwards to the masses of Europe and Asia with incredible slowness. Nor in the age of craftsmanship could it be otherwise. Beginning under the Romans, however, and gathering momentum during the Middle Ages in Europe, is a new trend that will break down such restrictions, the importance of which is fully recognized by Prof. Forbes. This is the use of powered machines. The most astonishing fact in his book is given on p. 328: half the available energy in the United States is consumed by its inhabitants for their private uses, the other half being nearly evenly divided between manufacture and conversion-losses. That is the true sign of the affluent society.

The author, whose association with Royal Dutch Shell and experience as a historian of science and technology give him unique authority, has devoted more than a third of his book to the earlier phase of man's career as a maker. This section of the book, though it can enter into little detail of how things were done by the laborious craftsman, gives a clear and balanced account of the origins of the chief manufactures; nor are their social effects ignored. The later and longer section on the last five hundred years has much detail of inventions and their development. Prof. Forbes shows a wise caution in appraising the contribution of pure science to invention and the revolution in technology: the importance of science in this respect is little more than a century old. The extension of the wind- or water-driven machine from corn-milling to fulling, smelting, pumping, spinning and weaving; the use of coal as a fuel and cast iron as an engineering material; the mastery of steam and the beginnings of industrial chemistry were all effected through craft empiricism. Changes in industrial organization were scarcely less productive than the new techniques. The effects of science in the nineteenth century were wrought on a world already changed, crudely perhaps, yet reaching towards "a rational exploitation of the material world on behalf of the common good". Through machinery and power, through book-printing and cotton-manufacture, railways and precision lathes, sulphuric acid, soda and glass, quantity production was offering the earth-bound peasant more than the whole history of craftsmanship had ever provided for the few. That, one cannot deny, is progress in making.

The text of "Man the Maker", now re-issued, is identical (even to misprints) with that issued by Henry Schuman (New York) in 1950. The author has enlarged the epilogue by several pages and has revised the bibliography. Although historians of technology are not idle, the book is still the broadest, most readable and complete survey of the field. It is written with continuity, perspective and social sense. Some casual statements that will annoy specialists and a number of relatively trivial slips in date and name might have been corrected, but these are minor blemishes on a work that will open a new prospect of the past to many readers.

A. R. HALL

HEAVIER ELEMENTS

The Transuranium Elements

By Glenn T. Seaborg. (Yale University—Mrs. Hepsa Ely Silliman Memorial Lectures.) Pp. xx+328. (London: Methuen and Co., Ltd., 1958.) 50s. net.

THE material in this book was originally presented at Yale University in lecture form during 1957. After considerable expansion, it was published as one of the series of books produced by the Addison-Wesley Company and presented by the United States Government to foreign delegates at the United Nations Conference on the Peaceful Uses of Atomic Energy, Geneva, 1958. It is now available in a different binding published in Great Britain by Methuen.

Prof. Seaborg has a well-established place in the discovery and elucidation of the complex chemistry of the transuranium elements, and any new publication by him is deserving of our close attention. This book is not, however, written for the specialist in this field and is of quite a different character from the highly successful volume "The Chemistry of the Actinide Elements" written in collaboration with J. J. Katz. Moreover, much of the basic material has appeared previously.

There are four main sections. The first is historical, beginning with a detailed description of the discovery of plutonium early in 1941, and continuing through the development of methods for its large-scale separation, with some digressions on the related actinide elements. This section is not easy reading despite the introduction of a considerable number of personal recollections of important events: the inclusion of long lists of names in the running text is distracting. The emphasis is on the chemists whose contribution to the success of the war-time project for the synthesis and separation of plutonium was only briefly mentioned in the Smyth Report of 1945. Although the reviewer is not in a position to judge the accuracy of detail in the accounts given of this very early work in the United States, some errors and misleading statements were detected in the brief references to the British project. As examples, no distinction is made between R W. Spence (of Los Alamos) and R Spence (of Harwell) on p 73 and in the index, and the work of Welch and collaborators on plutonium compounds (pp 87–88) is erroneously quoted as having taken place at Harwell rather than at Windscale The brief description of the Chalk River Laboratories (p 73) does not mention the important laboratory-scale development of the Windscale plutonium separation plant during the period 1945–48

The second section of the book, in which the chemical properties of the actinide elements are discussed briefly in a correlative manner, is more digestible Although one must agree with the author that the main points of the actinide concept are now well established, there will still be many chemists reluctant to see the undiscovered element 104, instead of thorium, taking the eka-hafnium position in the periodic table At the end of the book there is a shorter fourth section in which Prof Seaborg attempts to extrapolate the generalizations he has derived to predict the chemical and nuclear properties of elements well beyond those which have yet been successfully synthesized The magnitude of the experimental problem of isolating such elements is illustrated by a detailed description of the discovery of element 101 Since an average of only one atom of element 101 was expected to be produced in each experiment, the subsequent separation and identification must rank as one of the most outstanding feats in the history of chemistry

The most valuable part of this book is the third section, which deals systematically with the nuclear properties of the trans-uranium elements However, there is here, as in the rest of the book, a complete lack of detailed reference to sources of information

In summary, the book, though containing much material of interest, is written in such a way as to fall rather awkwardly between two stools Specialists in the field will prefer other expositions on the subject by the same author, while the layman interested in scientific matters will find difficulty in following the book, as a considerable background of scientific knowledge is required for a full understanding of even the historical sections

The book is well produced, with a commendable lack of typographical errors J K DAWSON

SCIENCE EDUCATION

The Challenge of Science Education

Edited by Joseph S Roucek Pp xiii+491 (New York Philosophical Library, 1959) 10 dollars

WHEN *Sputnik* was announced to a startled world in October 1957, the reaction in the United States was immediate and vigorous, but nowhere was it more unsettling than in certain radical proposals for revolutionizing the American educational system by copying that of the U S S R This book is an attempt to make a first systematic survey of the post-*Sputnik* educational practices in the field of science in the United States, the U S S R and Britain The work is edited by a former Czech, who commences with a brilliant, short historical account of the impact of science upon human thought and behaviour More than thirty collaborators are each responsible for a chapter, and these include Dr James R Killian, lately consultant to President Eisenhower, and Dr Werner Heisenberg The contributions differ in size and value as is to be expected, and the treatment of the subject is generally diagnostic and experimental rather than conclusive Standards and content in American science education vary more by reason of geographical location, religious and political factors than they do in Britain, though so far as the last is concerned, even here it still remains to be seen whether politics, which has invaded the field of secondary education, as in Derbyshire, will prove harmful to science teaching at a high level in the grammar schools The salary-levels, which affect the recruitment of suitable men and women to teach science, operate in the United States more forcibly than in Britain, and there is the added difficulty of the lower rating in social status "Don't become a teacher," said the head of one science college in the United States, "we want to be proud of all our men "

Werner Heisenberg's defence of a background education in the classics in relation to his own mental development as a theoretical physicist is most interesting and suggestive , and so are the chapters on new approaches to mathematics teaching by using the theories of sets and probability The underlying tone of the book is by no means optimistic There is a quotation from Don K Price ("Government and Science"), who concludes that "The role of world leadership is an uncomfortable one , it requires a steadiness of purpose, an economy of our energies and a breadth of philosophy that have never been characteristic of American temper"

The short account of science education in Great Britain (though it might have been more accurate to say England) by Dr Kenneth Laybourn of Bristol and the longer account of the U S S R by L A D Dellin of Vermont are very useful summaries

The documentation at the end of each chapter is excellent Every chapter is worth reading and pondering on, particularly by those who are interested in science and mathematics teaching, but generally by those who have any interest in maintaining the free world W L SUMNER

SIR CHARLES HASTINGS

The Life and Times of Sir Charles Hastings, Founder of the British Medical Association

By William H McMenemey Pp xii+516+32 plates (Edinburgh and London E and S Livingstone, Ltd , 1959) 50*s* net

IN 1951, Dr W H McMenemey was invited by the Council of the British Medical Association to deliver the first Sir Charles Hastings memorial oration, for which task he was singularly well equipped, for he had worked for several years as pathologist at Hastings's own hospital, and in 1947 had made a name for himself with his scholarly and charmingly written "History of the Worcester Royal Infirmary" An elaboration of this oration, "The Life and Times of Sir Charles Hastings" is a huge tome to which the hackneyed phrase "labour of love" may unhesitatingly be applied It will for long remain the standard biography of the founder of the British Medical Association and of the architect of the Medical Act of 1858 Dr McMenemey possesses a scholar's conscience in consulting original sources, and he quotes extensively and happily from contemporary medical periodicals, newspapers, minutes and letters, yet he wears his learning lightly and unobtrusively, and his style is both elegant and delightful. Some readers might criticize his story on the grounds that it is too detailed and too discursive, and that the lengthy accounts of his contemporaries detract from a true appreciation of the subject proper of the biography; but even those who would have preferred a more succinct narrative will yield to none in their admiration for an invaluable work of reference.

We meet Charles Hastings as a medical student at Edinburgh, where he developed "a catarrhal inflammation of the lungs", which was treated by the distinguished physician, James Gregory, and we learn that this malady inspired his lifelong interest in diseases of the chest. In 1820 was published his classic "Treatise on Inflammation of the Mucous Membrane of the Lungs", which was translated into German two years later. We accompany him to Worcester, where he was appointed physician to the Infirmary, and watch him first using the stethoscope in the summer of 1820. We read how he founded, and edited, the *Midland Medical and Surgical Reporter* in 1828, and in 1832 launched the Provincial Medical Association, which was watched by Thomas Wakley in London "carefully and with considerable suspicion". Little did Wakley realize that one day it would grow into a British Medical Association. Hastings was "the pivot around which the Association revolved, for they all looked to him for guidance and inspiration". We are told that he narrowly escaped becoming mayor of Worcester, paying a fine of £50 for having refused office. We see him in the role of naturalist and in his company attend a dinner where twenty toasts were drunk. "When the celebrants finally arose they had completed just over six wonderful hours of feasting and conviviality." It is interesting to find that in 1844 a National Association of General Practitioners was formed with seventeen branch secretaries.

Lavishly and fascinatingly illustrated, Dr. McMenemey's book bristles with bitter controversies in "disturbed and disputatious" meetings. It concludes with a bibliography of Hastings's writings, a general bibliography, and a model index. I like the chapter headings.

W. R. BETT

PANBIOGEOGRAPHY

Panbiogeography or an Introductory Synthesis of Zoogeography, Phytogeography, and Geology, with Notes on Evolution, Systematics, Ecology, Anthropology, etc.

By Léon Croizat. Vol. 1: The New World. Pp. 1018. Vol. 2a: The Old World. Pp. iii+1–771. Vol. 2b: The Old World (continuation). Pp. iii+772–1731. (Codicote, Nr. Hitchin: Wheldon and Wesley, Ltd., 1958.) £16 10s. (paper bound).

IT is a distinct understatement to call this enormous work unusual. Published in three separate books making up two volumes which weigh something like ten pounds unbound, it contains 2,700 pages and probably at least a million words. To this must be added that it is highly prolix and repetitive; that it is written in a peculiar brand of semi-colloquial idiomatic English which often obscures the author's exact meaning; and that it contains too many animadversions on biologists with whose views Dr. Croizat is not in accord. In short, the author seems to have put almost every possible obstacle in the way of the reader who wishes first to understand and then carefully to consider his opinions. This is all a great pity because there are two excellent reasons at least why this *magnum opus* should on no account be regarded as unreadable and therefore safely to be ignored.

The first reason is that the book is a vast compendium of information about plant and animal distribution which is arranged and discussed on a geographical and not a taxonomic basis, thus making it much more valuable than it might otherwise be. Indeed, the broad sweep of its geographical background is one of the book's best features. The first volume begins with an introduction, which concludes with a remarkable piece of self-criticism by the author, and is thereafter concerned with the New World in general and then with Venezuela, Colombia, Ecuador, the West Indies and Galapagos (that is, with several crucial areas) in particular. The first book of the second volume deals with Africa, Eurasia, Malaysia and Australasia; the second book covers Polynesia and is thereafter made up of conclusions; a long epilogue on evolution; and various addenda, of which the most extensive is one on physical anthropology. The chapter of conclusions is the shortest of all the chapters but also the most readable.

The second reason is that Dr. Croizat is a man of quick intelligence who has for years pondered over many fundamental problems of biology, not only in its narrower sense, but also in its wider philosophical expression in which it comprehends the whole history of the human race and of its thought. His comments and beliefs on many such subjects are interlarded, as it were, through his immensely long recital of the data of biogeography, but they often reveal great discernment and may therefore be forgiven for any digressions they cause.

As regards biogeography Dr. Croizat's main thesis is that plant and animal distribution, using this word in its more particular sense of 'dispersal', must not be studied in isolation; it is simply one aspect of the three basic factors of evolution, namely time, space and form. To quote his own words, his book "replaces the Darwinian understanding of 'species' originating at some definite spot on the map and 'migrating' *via* 'occasional means' with a fitting understanding of form-making and translation in space as a single process".

Thus, this vast book is, in essence, a study in evolution, chiefly, but by no means only, from the biogeographical point of view. It is clearly inspired by the author's discontent with the approaches to this subject of Darwin, Wallace and some of their successors, and so it is yet another contribution to the swelling stream of opinion that the general biological outlook which we now call Darwinism, however great its value may have been in the past, is no longer a suitable vehicle for progress in the biological sciences.

The maps, with which the book is liberally supplied, are open to some criticism. Most of them might be clearer and too many of them are drawn on Mercator's projection, which is quite unsuitable for depicting biological distributions. Also, they are too plentifully supplied with arrows purporting to show movement along various 'tracks' of migration. It is easy enough to postulate tracks of this sort but it is quite another thing to produce satisfactory evidence to show which way along them movement has been.

Medical Surveys and Clinical Trials

Edited by L. J. WITTS, C.B.E.

Nuffield Professor of Clinical Medicine in the University of Oxford

During the present century a new technique of clinical research has been developed which consists of the study of disease in groups instead of—as in past centuries—in individual patients This book, which is the first to be written on this increasingly important branch of research, will prove invaluable not only to those holding full-time research appointments but also to all engaged in any branch of clinical medicine, whether as consultants or general practitioners.

The book is divided into two parts Part I, Methods and Part II, Applications The first part commences with a chapter on the general principles of group research followed by chapters on diagnosis in group research, prevalence surveys, prospective and retrospective studies, follow-up studies, prophylactic and therapeutic trials, the use of volunteers, controls, placebos, and questionnaires in clinical trials, and operational research in medicine

The second part shows how these methods may be applied in many different branches of medical science, each chapter being illustrated by a number of relevant examples which show what has already been achieved by these methods of research No attempt has been made to include all branches of clinical medicine but those selected for detailed discussion provide ample information for workers in any other branch of medicine. Part II contains chapters on genetics, the assessment of nutritive child development and health, chest diseases, cardiovascular diseases, diseases of joints, mental illness, cancer, and tropical diseases

Each chapter contains a full list of references and, in addition, a bibliography on observer variation and error has been included

Every author has written from wide personal experience and all have made a number of distinguished contributions to medical research, many of which are used as the actual working examples that appear in the different chapters of this book

Plant Growth Substances

By Prof. L. J. Audus. Second edition. (Plant Science Monographs, No. 1.) Pp. xxii+554+34 plates. (London: Leonard Hill (Books), Ltd., 1959.) 65*s*. net.

To produce within a single volume a comprehensive and up-to-date treatment of a subject which is developing so rapidly as plant growth substances is no mean achievement. Yet in this second and revised edition of his book, Audus has done this with considerable success. As in the first edition, physiological aspects of growth-regulating activity receive careful attention throughout, but in addition a new chapter on the mechanism of action of the auxins, dealing with more fundamental physiology, is now included. Other changes in the book are shown in the more detailed treatment given to flowering control and chemical control of sexual processes in lower plants and to non-auxin type growth substances. The chapter on the chemistry of the auxins has also been considerably expanded.

Although this is an excellent book, it is perhaps pertinent to ask whether it is attempting to cater for too many classes of reader. In the reviewer's opinion, most of the contents are far beyond the reach of the "non-scientific layman", whose requirements would perhaps be met better by a book written specifically for him.

With this reservation, the present volume can be confidently recommended. It is well produced with excellent photographs and diagrams. Many references to original work are given and appendixes relating to the practical use of growth substances in agriculture and horticulture are provided. R. L. Wain

The Design of Physics Research Laboratories

A Symposium held by the London and Home Counties Branch of the Institute of Physics at the Royal Institution, 27 November, 1957. Pp. 108. (London: Chapman and Hall, Ltd.; New York: Reinhold Publishing Corporation, 1959. Published on behalf of the Institute of Physics.) 21*s*. net.

The proceedings of the symposium on "The Design of Physics Research Laboratories" held on November 27, 1957, at the Royal Institution and organized by the London and Home Counties Branch of the Institute of Physics have now been published in book form. A report of the symposium appeared in *Nature* (**181**, 90; 1958). The symposium was very timely and extremely successful. It was attended by some 400 architects, physicists and others interested in the design of research laboratories, and the book contains a full account of the proceedings, including the discussion and many of the photographs which were presented as lantern slides. Nobody who is about to plan a new physics laboratory or an extension to an existing laboratory should omit to read this volume first. It contains a wealth of excellent hints and reminders, and may save much expense in assisting to avoid faulty design and much time in providing quick and accurate reference to the authoritative literature. It is difficult to summarize the contents, but all those who have had experience of planning buildings and the responsibility of supervising the construction will agree most wholeheartedly with the statements that properly planned sound construction using lasting and easily maintained materials is the most economical, and that regular site meetings should take place between the user of the building, the architect and the most essential person, whom Mr. Emmerson calls "the building supervisor" and who should be the sole official channel of communication between the various parties concerned in the building of the laboratories. S. Weintroub

Aromatic Substitution

Nitration and Halogenation. By Dr. P. B. D. de la Mare and J. H. Ridd. Pp. vii+252. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1959.) 50*s*.

This book deals with the nitration and halogenation of aromatic compounds. Two introductory chapters cover the basic principles of electronic theory and methods used to investigate reaction mechanisms. Next follows a group of four chapters dealing with methods of nitration and the mechanism of the nitration reaction, and then a further group of four chapters dealing likewise with halogenation. The authors then review substitution in diphenyl, in polycyclic hydrocarbons, in non-benzenoid hydrocarbons, and in heterocyclic systems, and substitution reactions involving displacements of groups other than hydrogen. The final chapters deal with molecular orbital calculations of reactivity and with linear free energy relationships.

The authors have succeeded in giving an excellent, well-written and critical account of their subject. Although the book is both short and readable, no important aspect seems to have been omitted and no important papers overlooked. The authors have not been afraid to express forceful opinions on a variety of controversial issues—a pleasant phenomenon in this era of depressingly uncritical compilations. The book is, moreover, very well produced and the price most reasonable. It can be strongly recommended to any chemist interested in organic reaction mechanisms. M. J. S. Dewar

Constitutional Diagrams of Uranium and Thorium Alloys

By Frank A. Rough and Arthur A. Bauer. (Addison-Wesley Physics Books.) Pp. vi+154. (Reading, Mass.: Addison-Wesley Publishing Company, Inc., 1959.) 5 dollars.

This book, which supersedes the Battelle Memorial Institute publication, "Compilation of U.S. and U.K. Uranium and Thorium Constitution Diagrams", is a new compilation of United States and United Kingdom uranium and thorium constitutional diagrams. The book is divided into two major sections, one for uranium and the other for thorium. Each section is preceded by a short account of the transformation temperatures and crystal structures of the base metal. The method of presentation is the constitution diagram, with a short account of the investigations on the system, the essential data on the crystallography of the compounds and a list of references for each alloy. Most of the references are unclassified, but in several systems, where the unclassified literature is incomplete, some classified references are given. The various systems are listed in alphabetical order and include both binary and ternary alloys. The information on each alloy is quite comprehensive and the form of presentation is neat and concise. This publication will be extremely useful as a reference book to everyone interested, either from a theoretical or practical point of view, in the alloys of uranium and thorium. D. E. R. Hughes

SHIP HYDRODYNAMICS LABORATORY, FELTHAM

ON October 19, H.R.H. the Duke of Edinburgh opened at Feltham the new Ship Hydrodynamics Laboratory of the National Physical Laboratory.

Since 1932, when No. 2 Tank was built at Teddington, test work on models of new ships has increased in volume to a point where it has seriously impeded research. At the same time, thanks to the steady investigations undertaken over the past fifty years, research requirements have themselves changed. Increasing emphasis is falling on the seagoing qualities of ships, particularly at high speeds, and the facilities at Feltham have been specially designed for these requirements. It is expected that, in general, tests of commercial ship-models in smooth water will continue to be carried out at Teddington, while tests of commercial models in rough water and a great deal of the research will be done at Feltham. This research will include theoretical and experimental studies of ship motions in regular and irregular seas, together with a study of full-scale multi-directional sea states, propeller and hydrofoil cavitation and ship vibration. Various other research projects formerly followed at Teddington will be carried over to Feltham, where larger models can be used than is possible in the existing tanks; these will include skin friction of smooth and rough surfaces, ship-model correlation, wave-making resistance and boundary-layer investigations.

The design of the new Laboratory (Fig. 1) was developed by the Ship Division of the National Physical Laboratory working in collaboration with the Chief Architect's and Chief Engineer's Divisions of the Ministry of Works. The principal facilities at Feltham comprise a towing tank, a sea-keeping and manœuvring basin and a propeller water-tunnel for cavitation research.

The ship-testing tank is the largest of its kind in Britain. It is 1,300 ft. long, 48 ft. wide and 25 ft. deep. Its length, which is almost double that of the No. 2 Tank at Teddington (680 ft.), is necessitated by the requirements of testing models in irregular seas or at high speeds and the use of larger models of multi-screw ships. In sea-keeping tests the model must be run through regular and irregular seas for long enough time to obtain complete cycles of motion and also to ensure a long enough steady run for making measurements at high speed. The original design was for a length of 1,800 ft., but this had to be reduced in order to keep within the funds available, and the present length represents the minimum for fulfilling these requirements. The site, however, has been planned so that the additional length can be added in the future.

Fig. 2. Carriage and main towing tank, 1,300 ft. long

The tank itself has been built of reinforced concrete sections. It is above ground-level, as the expense of keeping out the subsoil water would have been heavy in this area, where the water-table is very near the surface. Special care has been taken in the heating and ventilating arrangements to keep an even temperature in the building in order to maintain accurate rail alignment, avoid condensation effects on electrical equipment and ensure a reasonably constant nominal water temperature of 60° F.

The towing carriage (Fig. 2) is designed to tow ships' models up to 5 tons in weight and 40 ft. in length. The maximum speed attainable is 50 ft./sec., but this would not be used with heavy ship models. The carriage has four girders forming a square framework 50 ft. × 50 ft. externally, completely open inside, giving a space 36 ft. square. Into this centre space a fore and aft girder containing dynamometers and other instrumentation can be placed in a number of positions to give flexibility in carrying out different types of tests.

To decrease the effects of track deflexion and thus assist in providing undisturbed and uniform motion, the carriage is driven by four twin-wheel self-steering bogies on which the frame is in effect pivot-mounted via a system of rubber compression springs. Each bogie is powered by a 300 h.p. peak rating d.c. motor. The total peak power of 1,200 h.p. has been calculated to provide, with adequate margin, sufficient power to accelerate the carriage, which will weigh nearly 40 tons fully equipped, at the maximum rate without wheel slip. This value will have to be determined precisely by experiment, but will be of the order of $0 \cdot 1g$. Wind-tunnel tests have been made on a model of the carriage frame to help assess accurately the wind loadings at high speed.

The carriage is equipped with a speed-holding servo which will maintain any set test speed between 10 and 50 ft./s. within 0·1 per cent of the set speed. Much study has been given to the braking system necessary. The normal method of braking will be electrical, but at high speeds a system of mechanical friction brakes will be brought into use, which are spring operated and held off pneumatically so that they fail to safety in the event of loss of air supply. To limit the duration of the test run, track switches have been installed to bring on both electrical and mechanical brakes and bring the carriage to rest with a maximum deceleration rate of $0 \cdot 25g$. Should all these systems fail, an aircraft arrester gear has been fitted, with cables on each side of the tank. A shock-absorbing nylon harness on the underside of the carriage will engage hooks located on the inside face of the tank walls.

The investigation of the behaviour of vessels in a seaway demands the generation of regular and irregular wave systems in the tank. A wave-maker has been installed at one end of the tank capable of making waves up to 40 ft. in length and 2 ft. in height from crest to trough with an infinite variety of possible combinations within these limits. The wave-maker takes the form of a wedge-shaped plunger 17 ft. in height which spans the tank and tapers almost to a point at the bottom. The front face is curved to follow a theoretically ideal contour and is true to within $\pm \frac{1}{8}$ in. over the whole frontal area. The plunger moves vertically on slides on the end wall of the tank and is driven by hydraulic rams from a pump which operates normally on a sinusoidal pressure cycle to give a regular train of waves. By varying the pressure cycle it will be possible to generate irregular wave systems more typical of average ocean sea-states. To prevent reflexion of the waves from the other end of the tank, an end beach has been provided. This consists of a curved sloping surface, continuous below water and slotted in and above the water. It can be raised or lowered by means of buoyant chambers.

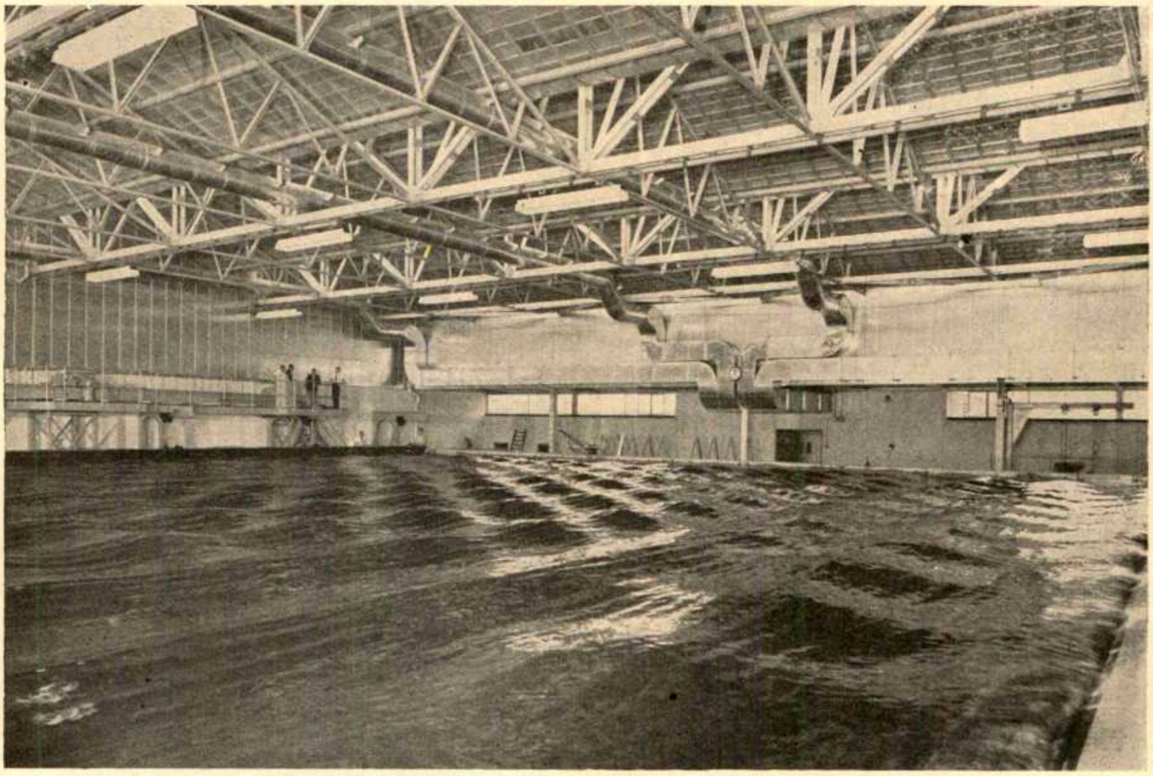
When tests are being made with a model in smooth water, she creates her own wave system, and time has to be allowed between successive runs to allow these waves to die down. In order to reduce this waiting time to a minimum, a similar beach is fitted in front of the wave-maker and can be raised to the surface when required. In addition, there are side beaches consisting of continuous lengths of curved flaps on either side of the tank which are hinged to the tank walls so that they can either be raised into a vertical position clear of the water when making waves or let down and partly submerged for still-water testing.

In long towing tanks the behaviour of models can be studied under conditions of head-on or stern-on waves. It has long been desired at the National Physical Laboratory to carry out tests in waves at different angles to the heading of the model and in confused seas and to investigate manœuvring qualities generally. This will now be possible at Feltham, with the new manœuvring and sea-keeping basin (Fig. 3), which is 100 ft. square with a depth of water of 8 ft. A plunger-type wave-maker has been fitted along one side capable of producing waves up to 15 ft. long and 9 in. high. A beach has been fitted on the opposite side. It is intended later to fit another wave-maker on an adjacent wall, and this may be articulated, to enable confused seas to be generated.

Models up to 10 ft. in length can be used in this tank, and as they are to be free-running, they must carry their own source of power and instrumentation. They must therefore combine lightness with strength, and will in general be made of fibre-glass plastic. They will be radio-controlled from shore, and the instrumentation in the models will either record its own data or telemeter them ashore. The Control Mechanisms and Electronics Division of the Laboratory is assisting in the development of a tracking system.

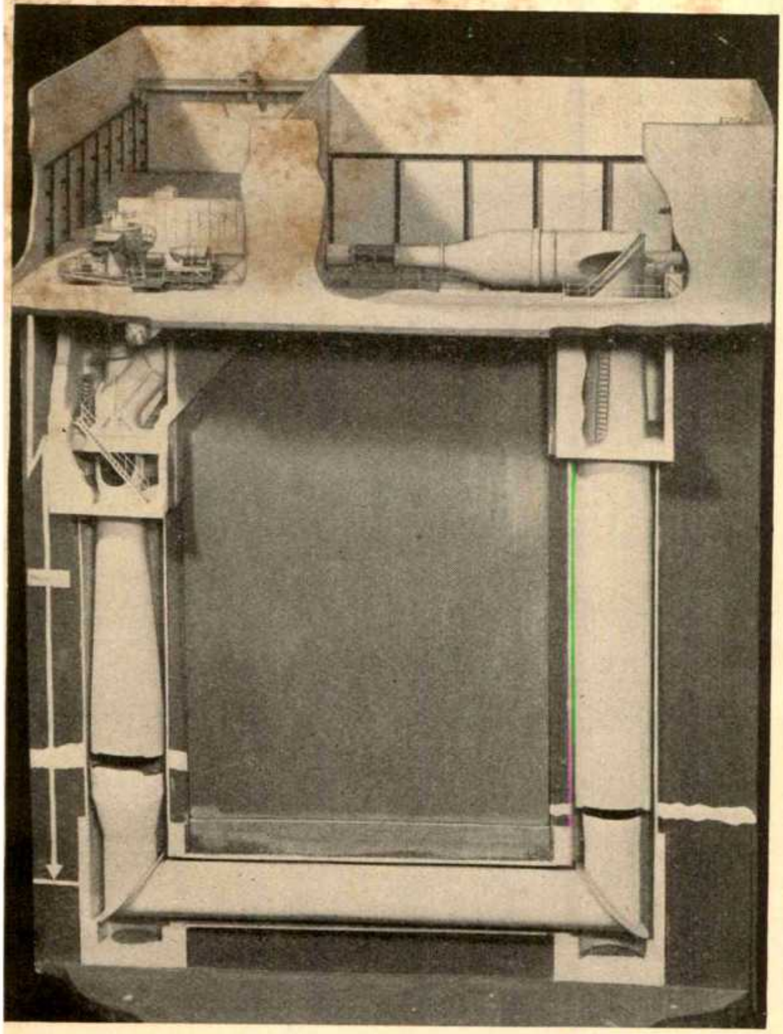
The new water tunnel (Fig. 4) is intended primarily for research work on propellers up to 24 in. in diameter and can also be adapted for testing hydrofoils and similar bodies. This work is likely to grow in importance with the increasing demand for high speeds in ships of all classes. The tunnel is one of the largest of its type, with a circular closed test section 44 in. in diameter; it is designed for a maximum water velocity in the working section of 50 ft./s.

The tunnel shell is arranged as a rectangular circuit of which the upper horizontal limb is at ground-level. This portion includes the contraction section, where the water is accelerated to the working-section velocity, the working section itself and the transition and diffuser sections, where the speed of the water is gradually reduced before entering the suction side of the pump. The remaining portions of the tunnel form a U-shaped circuit descending 180 ft. into the ground and forming a 'resorber'. This is designed to subject the water to an additional static pressure-head during transit, when all bubbles created by cavitation at the model and released into the water stream are re-absorbed into solution.



[Crown copyright reserved

Fig. 3. Sea-keeping tank



[Crown copyright reserved

Fig. 4. Model of the water-tunnel showing underground portion

The water will be circulated around the tunnel by a 92-in. diameter vertical variable-pitch pump driven at a maximum speed of 220 rev./min. by an 850 h.p. mean continuous rating vertical d.c. motor, which is equipped with automatic speed-holding equipment designed to hold any set speed with an accuracy of 0·1 per cent.

The model propeller is mounted on a downstream shaft, fitted with thrust and torque dynamometers and driven by a 300 h.p. motor. The pressure in the test section can be varied from near zero to 6 atmospheres absolute. The tunnel is fitted with stroboscopic lighting and high-speed photographic equipment.

There are a number of small laboratories devoted to the development of new instrumentation, a photographic room and a vibration laboratory containing a water tank 20 ft. by 14 ft. and 6 ft. deep for experiments on virtual mass and similar problems.

The Laboratory is fully equipped with workshops for making wax, wood and plastic hull models, and casting and finishing propeller models in bronze. The office block includes a handsome library, a dining room and kitchens. The offices and workshops have been occupied since August 1958, and much of the new instrumentation has been built in the shops.

The new Ship Hydrodynamics Laboratory will be under the personal direction of Dr. F. H. Todd, superintendent of the Ship Division of the National Physical Laboratory.

LOCALIZATION AND ASSAY OF RESPIRATORY ENZYMES IN SINGLE LIVING CELLS

Absorbancy Measurements on the *Nebenkern*

By Dr. ROBERT P. PERRY*, Dr. Bo THORELL, Dr. LENNART ÅKERMAN
and Prof. BRITTON CHANCE

Johnson Research Foundation, University of Pennsylvania, Philadelphia, Pennsylvania,
and Department of Pathology, Karolinska Institute, Stockholm

A STUDY and selection of appropriate optical, electronic, and photoelectric components now permits remarkable sensitivity in the detection of small changes of absorbancy caused by enzyme reactions in living materials. In the case of suspensions of whole cells or cell particles, a detectability of 10^{-11} mole can be achieved without difficulty in a 1-c.c. cuvette of a recording spectrophotometer[1]. Microspectrophotometry affords an even more favourable situation for the study of small amounts of biological materials in that measurements can be localized to specific parts of single living cells, and the cells themselves may be selected on the basis of temporal or morphological criteria. Hitherto, however, it has been used mainly for the evaluation of substances present in relatively high concentrations, such as proteins and nucleic acids[2], and for studies of the formation of hæmoglobin in erythroid cells[3,4]. So far only limited success has been had in measuring those pigments of the single cell which are present in 'enzyme' concentrations, since this requires sensitivities in measuring changes of absorbancy between one-tenth and one per cent over an aperture of about a micron.

---

* Present address: Laboratory of Animal Morphology, Free University of Brussels, Belgium.

This communication reports the application of a combination of a highly sensitive recording circuit and the microscopic technique[5] which permits the assay of the cytochromes localized in single mitochondrial aggregates, particularly the 5-μ diameter *Nebenkern* of grasshopper spermatids, with an accuracy of several per cent. This sensitivity allows the detection of 10^{-20} mole or 6,000 molecules of the cellular enzyme, cytochrome *b*. The following communication describes localized measurement of the fluorescence of pyridine nucleotide of the *Nebenkern* and that of mitochondrial aggregates of other types of cells with a sensitivity comparable to that of this instrument.

The optical system used is similar to that described by Thorell and Åkerman[4]. It employs a 250-mm. focus, grating monochromator, a 1·6-mm. Grey reflecting water-immersion condenser and objective (N.A. = 1·0), and a 3·5 × quartz ocular which projects the beam on to a vibrating mirror assembly. The photomultiplier is type 1*P*28 and operates in the range of total voltage 400–650 V. The tungsten lamp is given an overvoltage of approximately 30 per cent to provide adequate illumination. The spectral interval of the monochromator is approximately 3 mμ. The amplitude of the vibrating mirror corresponds to approximately 12μ. The hole in front of the photocell corresponds to a 1·5-μ diameter aperture.

The electronic circuit incorporates the dynode feedback circuit of Picard[6] as previously used by Yang[7] and Åkerman[8]. The circuit is insensitive to grid and dark currents, and will operate at very low signal-to-noise ratios due to a switching circuit that adds a signal to the phototube output exactly equal to that of the reference signal (~ 1 V.). Thus the output wave-form consists of alternate pulses: reference beam, dark, measuring beam, dark, in a balanced wave-form with no 'pips' for equal reference and measurement signals (Fig. 1). This signal can be highly amplified without amplifier overload and demodulated to give appropriate signals for control of the dynode voltage (reference minus dark) or measurement of absorbancy (reference minus measure). The noise-level of the spectrophotometer at 420 mμ is about 10^{-4} in optical density units with a 2·5-sec. time constant.

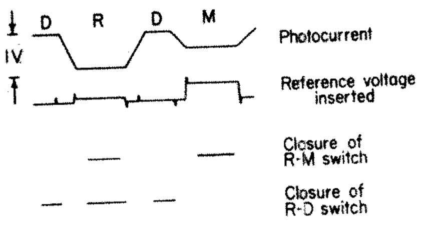


Fig. 1. Wave-form diagram illustrating the principle of operation of the electronic circuit of the microspectrophotometer. As indicated in the left-hand scale, the amplitude of the wave-form is slightly less than 1 V. The top trace represents the wave-form of the photocurrent after electron amplification. The portions labelled *D* are those corresponding to the dark interval and those labelled *R* and *M* refer to the intervals during which the light passes through the material in the reference and measuring areas. The second trace represents the wave-form after 1 V. has been inserted into the wave-form at intervals *R* and *M*. A measurement of the absorbancy difference between the *R* and *M* optical paths is made by a closure of the *R* – *M* switch. Control of the dynode voltage for the photocell in response to any deviation of the *R* – *D* difference from 1 V. is measured by the closure of the *R* – *D* switch (*MD* – 82)

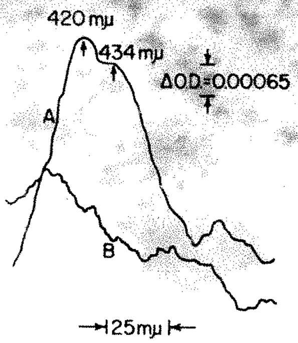

Fig. 2. Spectrum of anaerobic spermatid. Trace *A* represents the difference of absorbancy between the *Nebenkern* and the adjoining free space. Trace *B* represents the difference between the cytoplasm of the cell and the adjacent free space. The recording is on a linear wave-length scale (*RP* – 1)

Spermatid preparations were made from mature grasshoppers by Belar's method[9]. The cells were confined between a slide and coverslip suspended in about 3 μl. of buffer. Aerobic conditions were obtained in glucose-free suspensions for approximately 1½ hr. observation. Thereafter cell respiration exhausted the oxygen and the material contained in the suspension became anaerobic. By this simple method it was possible to obtain, in one experiment on a single *Nebenkern*, spectra corresponding to the oxidized and reduced forms of the cytochromes. If glucose was added to the buffer, anaerobic conditions were attained a few minutes after preparation. The anaerobiosis was monitored by the inclusion of some human erythrocytes under the coverslip, and the time of anaerobiosis was checked from measurements of the characteristic shift of the hæmoglobin absorption bands[4].

Fig. 2 shows two traces obtained from a single anaerobic spermatid in a preparation treated with glucose. Curve *A* illustrates the absorbance of the *Nebenkern* measured with respect to the surrounding free space; curve *B* records the absorbance of the cytoplasm of the spermatid, also with respect to the surrounding free space. The *Nebenkern* shows an absorption maximum at 420 mμ with a distinctive shoulder at 434 mμ.

Observations of the *Nebenkern* in a glucose-free suspension 70 min. after closing the preparation with a coverslip show a single peak at approximately 413 mμ, such as that shown in Fig. 3. Other experiments in which the spermatid respiration was inhibited by iodoacetate show, for a considerable interval, the single peak characteristic of the cytochromes, mainly in the oxidized state.

The measurement of the *Nebenkern* under aerobic or anaerobic conditions invariably gives clear Soret

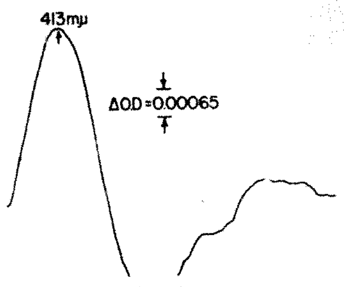

Fig. 3. Spectrum of aerobic spermatid, *Nebenkern* versus nucleus. Spectrum recorded 70 min. after preparation of glucose-free material (*RP* – 6)

peaks 413 mμ for aerobic conditions and 420 and 434 mμ for anaerobic conditions These are almost identical with the theoretical composite curves constructed from the known spectra of reduced or oxidized cytochromes *a*, a_3, *b*, and *c* mixed on an approximately equimolar basis Preliminary attempts have been made to examine the alpha bands of the cytochromes, but inadequate sensitivity is available with the light intensity, photosensitivity, and response times used at present However, some encouraging preliminary results have been obtained with liver cells, as described in the third communication of this series

The curves of cytoplasm or nucleus versus free space are monotonic functions which may show a systematic deviation corresponding to about 2×10^{-3} optical density units per 100 mμ change of wave-length The direction of the shift is variable and depends upon the combination of instrumental error and differences of light-scattering in the specimen

Errors due to the motion of the cell can be readily observed and precautions are taken to record only those cells which are immobilized at the glass surface by surface tension or are entangled in the tails of mature sperm The error due to motion can be negligible under favourable conditions compared to the intrinsic noise of the spectrophotometer The average reproducibility for several curves is approximately 3×10^{-4} optical density units.

The remarkable absorption of the *Nebenkern* and the lack of any significant absorption, in this wave-length range, of the cytoplasm give direct support to the current idea that the bulk of the respiratory activity is associated with the mitochondrial bodies The experiments reported here show that the *Nebenkern* contains *in vivo* at least 50 times more cytochromes per unit volume than any other comparable part of the cell

An estimate of the concentration of cytochrome in the single *Nebenkern* based upon these data (Δ O D at 425–430 mμ = 5×10^{-3}), an extinction coefficient of reduced cytochrome *b* of 160 cm $^{-1}$ mM^{-1}, and an estimate of 60 per cent contribution of cytochrome *b* to this peak, gives an effective concentration of 36 μmoles per litre over a 7 5 μ^3 volume of the *Nebenkern* Assuming equimolar amounts of the four principal cytochromes, the total cytochrome concentration is 144 μmoles per litre or about 10^5 molecules per μ^3 If the difference of optical density is expressed in terms of the amount of cytochrome *b* in a 7 5-μ^3 volume, one obtains 5×10^{-19} mole or 30,000 molecules Since the signal-to-noise ratio is about 50 1, the error in detection corresponds to 10^{-20} mole or 6,000 molecules This value compares very favourably with that obtained by any other method for the determination of the amount of an enzyme concentration *in vivo*

Fluorescence Measurements of Mitochondrial Pyridine Nucleotide in Aerobiosis and Anaerobiosis

By Prof BRITTON CHANCE

Johnson Research Foundation, University of Pennsylvania, Philadelphia, Pennsylvania

AND

Dr Bo THORELL

Department of Pathology, Karolinska Institute, Stockholm

SPECTROSCOPIC observations of the large pyridine nucleotide content of isolated mitochondria[1] were recently supplemented by the demonstration of the intensified and shifted fluorescence of this substance in mitochondria[2] These results direct attention to the possibility of a close relationship between the blue autofluorescence of the living cells and that of the reduced pyridine nucleotide component of the mitochondria[1–6] This communication describes photoelectric measurements of fluorescence of mitochondrial bodies in the grasshopper spermatocyte The localization of blue fluorescence in mitochondrial aggregates has been demonstrated, and quantitative measurements of the kinetics of changes in response to aerobiosis and anaerobiosis have been made A comparison of the fluorescence of mitochondrial aggregates and the neighbouring cytoplasm during this change from aerobiosis to anaerobiosis may lead to a much clearer understanding of the dynamics of interaction of the cytoplasmic and mitochondrial pyridine nucleotide *in vivo* While the present technique has been applied only to cells showing large mitochondrial aggregates, the excellent performance obtained under these conditions may allow the study of much smaller numbers of mitochondria The combination of this instrument for measuring the mitochondrial pyridine nucleotide with that of a sensitive microspectrophotometer (see preceding communication) for the study of the cytochromes may provide a new method for following metabolic changes in cytologically defined parts of the living cell

The 1,000-watt, *AH*6 mercury arc illumination was filtered by means of a water-cooled Corning 584 filter (Marshall, personal communication), and by an 'Eppendorf' 366 mμ multi-component filter. Dark-field cardioid illumination of the sample was observed through a 100× adjustable aperture lens set at N A = 1 00 and a 10× ocular A 60-c /s. vibrating diaphragm[7] with an effective 5-μ aperture sweeps through an effective distance of 15μ and allows comparison of the intensity of fluorescent portions of the cell and the adjacent free space by means of an electron multiplier photocell The intensity of the a c -operated mercury lamp reaches a maximum at the excursions of the vibrating diaphragm (see Fig 1) Simultaneously, an electronic switch communicates signals to a storage condenser so that the difference of the intensities at the peaks of

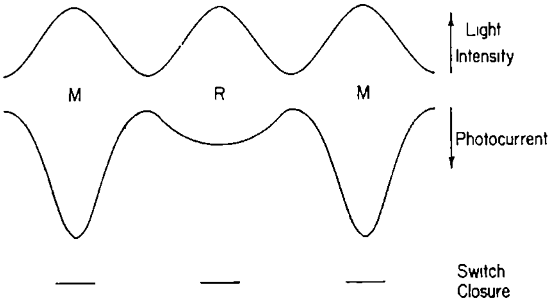

Fig 1 Wave-form diagram indicating the time relations of the light intensity, photocurrent, and switch closure for the microfluorimeter The top line represents the time-variation of the intensity of the mercury arc lamp The modulation frequency is 120 c /s , and the amplitude of modulation is nearly 100 per cent The second wave-form is that of the photocurrent after electron amplification (An increase of current is indicated by a downward deflexion) This wave-form is in response to a fluorescent object in the *M* position of the aperture, and the surrounding free space in the *R* aperture , the distance between *M* and *R* is approximately 15μ As indicated at the bottom of the trace, the closure of a synchronized mechanical switch is coincident with the peak of the *M* and *R* wave-forms The electronic circuit measures the difference between the amplitudes of the photocurrent at the *M* and *R* intervals (*MD* – 83)

the excursions of the diaphragm are recorded by a millivoltmeter, the sensitivity of which is 1 mV for 10^{-16} amp of primary photocurrent The average signal from the mitochondrial aggregate or *Nebenkern* (4×10^{-16} amp) gives a signal-to-noise ratio of the order of 30 1 with a time constant of about 2 sec

Localization of fluorescence in grasshopper spermatid Fig 2*a* represents recordings of fluorescence intensity as a function of time for two positions of the measuring aperture with respect to the cell At the left of the graph, the abrupt downward deflexion of the trace indicates opening of the photocell shutter and the maximal downward deflexion corresponds to the intensity of fluorescence of the *Nebenkern* measured with respect to the free space surrounding the cell By an adjustment of the air pressure on the movable stage[8] the cell is moved so that one aperture coincides with the cytoplasm Here a 50 per cent diminution of the intensity is noted The specimen (moved a distance of about 5µ) is then returned to its initial position so that the *Nebenkern* again coincides with the aperture, and the previous value of fluorescence intensity is obtained The record ends with the closing of the shutter In this way the fluorescence intensities of different portions of the cell can be scanned A schematic diagram of such a study (Fig 2*b*) indicates intensity measurements corresponding to the free space, cytoplasm, and *Nebenkern*, the width of the rectangles corresponding to the half-power response of the measuring aperture These results suggest that the fluorescence of the cell is highly localized in the *Nebenkern* body

The study of many anaerobic spermatids having *Nebenkern* indicates that the ratio of the fluorescence signal of the *Nebenkern* to that of the cytoplasm varies from a minimum of 1 7 1 to a maximum of 6 1, the average for ten cells being 3 3 1 The variation of these values may be due to a number of factors , for example, the position of the *Nebenkern* or the thickness of the cytoplasm in which a measurement is being made or the metabolic state of the spermatid A significantly higher fluorescence has been observed in the nucleus than in the cytoplasm, values ranging as high as 2 1 However, the biochemical significance of fluorescence other than that of the *Nebenkern* requires studies of its biochemical response to different oxidation-reduction conditions as described below

Biochemical response of the intensity of fluorescence In order to subject the *Nebenkern* of the living cell to a metabolic change which would specifically identify its fluorescence with that of mitochondrial reduced pyridine nucleotide of the respiratory chain, we have followed its time course in the transition from aerobiosis to anaerobiosis (see Fig 3) As described in the preceding communication, glucose-free spermatids will exhaust the oxygen under a coverslip in about 90 min In the microfluorimeter, a coverslip of smaller diameter and a smaller liquid volume are used It is calculated that anaerobiosis can be expected in about 40 min The right-hand portion of Fig 3 (open circles) shows the fluorescence as a function of the time after excluding air from the preparation The fluorescence of the *Nebenkern* rises slowly for 40 min and then abruptly until a total of 60 min has elapsed Thereafter, the fluorescence of the *Nebenkern* is constant Measurements of the cytoplasmic fluorescence (solid circles) indicate no rise of fluorescence over the 90-min interval and there is some indication of a slight decrease In order to avoid prolonged ultra-violet radiation of a particular cell, three cells were studied in the course of the experiment and they are identified by the numbers along the abscissa In order to diminish instrumental error and any differences between the cells which might contribute an error to the right-hand portion of the figure, the results are plotted in the left-hand portion in terms of the ratio of the *Nebenkern* fluorescence to the cytoplasmic fluorescence , it is seen that the fluorescence increases slowly for the first 40 min , and then rises abruptly between 40 and 55 min to reach a plateau which is maintained thereafter This behaviour is characteristic of the transition from the oxidized to the reduced state of mitochondrial pyridine nucleotide in the transition from aerobiosis to anaerobiosis[1,2,9]

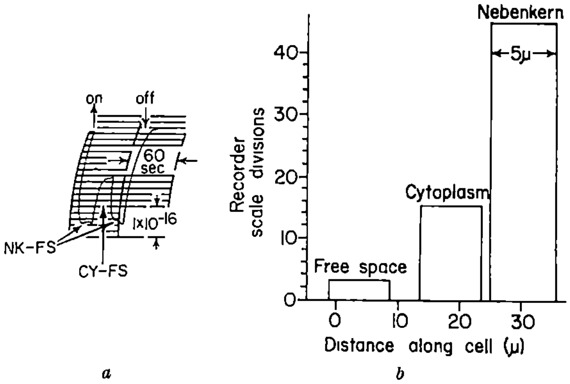

Fig 2*a* An example of the measurement of the fluorescence intensity of two portions of the grasshopper spermatid under anaerobic conditions The phototube shutter is opened and closed at the points labelled 'on' and 'off' The time scale runs from left to right , the initial reading is made with the measuring aperture on the *Nebenkern* and the reference aperture on the free space (*NK–FS*) The specimen is then moved 5μ by means of a flexible quartz plate, after which the tracing records the fluorescence intensity of the cytoplasm (*CY–FS*) The specimen is then returned to the initial position (*NK–FS*) and the shutter is closed The scale indicates the primary photo-current (1×10^{-16} amp per 5 scale divisions) (925*a*)

Fig 2*b* Scan of fluorescence intensities of anaerobic grasshopper spermatid The cell is moved with respect to the measurement aperture by means of the flexible quartz plate and positions are chosen with the measurement aperture on the free space, cytoplasm, and *Nebenkern* The cell boundary is approximately at the 10μ position on the scale of the abscissa (920*a*)

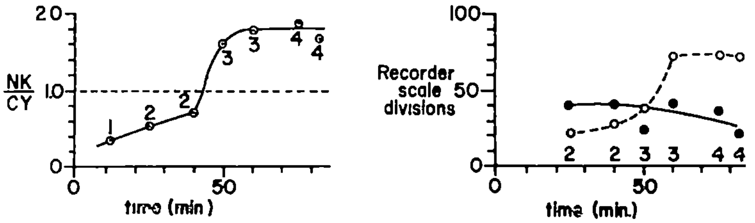

Fig 3 Time-course of the fluorescence changes of the *Nebenkern* (open circles) and the cytoplasm (solid circles) of a grasshopper spermatid during the aerobic–anaerobic transition On the right, the independent determinations in the cytoplasm and on the *Nebenkern* are plotted, on the left, the ratios of the two measurements The abrupt discontinuity at 45 min corresponds to the expected time for the exhaustion of oxygen under the coverslip The numbers adjacent to the circles refer to the cell which is under observation (922*a*,*b*)

These results appear to identify the *Nebenkern* fluorescence with that of reduced pyridine nucleotide If we assume that the cytoplasmic fluorescence is also due to pyridine nucleotide, these results suggest that there is no rapid change of the oxidation-reduction state of cytoplasmic pyridine nucleotide of the grasshopper spermatid associated with the aerobic–anaerobic transition

Studies of other cells Cells which do not show a distinctive localization of mitochondria, as does the grasshopper spermatid, do not permit a distinction between cytoplasmic and mitochondrial fluorescence However, in the anaerobic state, the greater fluorescence of mitochondrial material would lead at least to a preponderance of mitochondrial effects For example, observations of the effects of the transition from aerobiosis to anaerobiosis can be observed by measurements of the brighter portions in the cytoplasm of ascites tumour cells In these cells, the fluorescence is constant for about 10 min, rises for an interval of 10 min and then remains approximately constant (Fig 4) A comparison of this graph with the right-hand portion of Fig 3 (open circles) shows that the percentage increase is considerably less for a cell in which both cytoplasmic and mitochondrial fluorescences are summed, in fact, a curve similar to that of Fig 4 can readily be constructed from the results of Fig 3 if one plots the sum of mitochondrial and cytoplasmic fluorescence as a function of time

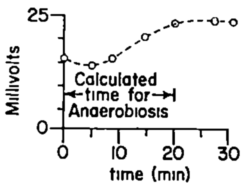

Fig 4 Time-course of the fluorescence changes of an ascites tumour cell during the aerobic–anaerobic transition The recording is taken from what appears to be a mitochondrial aggregate in the cytoplasm of the cell 'Calculated time for anaerobiosis' represents the number of minutes it should have taken the suspension to become anaerobic, if the respiratory-rate measured in the bulk phase were valid for the microscopic sample (929*a*)

It would appear therefore that, in spite of the inferior localization obtained with the ascites tumour cells, substantially the same results are obtained in the aerobic–anaerobic transition Similar results have been obtained for pentaploid yeast cells and preliminary studies of the application of this method to the kinetics of transfer of mitochondrial material from the mother to the daughter cell in budding yeast have been made

Discussion The blue autofluorescence of living cells and tissues has been indirectly associated with mitochondrial bodies by Sjostrand[3], who has studied in detail the fluorescence characteristics of thiamin and frozen dry sections of axons and of riboflavin in acid-treated groups of kidney cells (Sjostrand, unpublished work) However, no detailed investigations of the fluorescence of the living tissue were possible due to its relatively lower intensity Independent developments in the study of fluorescence of solutions of reduced pyridine nucleotide by Boyer and Theorell[4] and by Duysens and Kronenberg[6] have shown a characteristic shift and an enhancement of this fluorescence in the presence of enzymes which will bind the coenzyme The peak of this fluorescence is approximately 443 mμ Duysens and Amesz[5] have recorded a similar fluorescence in suspensions of yeast cells Spectroscopic observations of the high content of pyridine nucleotide in isolated mitochondria[1,9] have led to a study of their fluorescence[2] Here again a maximum at 443 mμ is obtained, suggesting that the reduced pyridine nucleotide of the mitochondria is in a bound form, and therefore that the blue autofluorescence of mitochondria of living cells may well be associated with its bound reduced pyridine nucleotide The experiments reported here verify the localization of a fluorescence characteristic of reduced pyridine nucleotide in the mitochondrial aggregate of the grasshopper spermatid and also show that it has excitation and emission characteristics which are not inconsistent with those of reduced pyridine nucleotide However, the following kinetic data give the most direct support for this supposition

First, the change of fluorescence in the grasshopper spermatid occurs at the time expected for anaerobiosis in view of the calculated respiratory activity of the cells Second the change of fluorescence is an increase, as expected from studies of suspensions of mitochondria or intact cells, that is, where increased reduction of pyridine nucleotide occurring in the aerobic–anaerobic transition leads to increased fluorescence of intramitochondrial pyridine nucleotide Thirdly, the fact that the *Nebenkern* shows some fluorescence in the aerobic state is consistent with the observation of a partial reduction of pyridine nucleotide in the steady state of metabolism, provided substrate is present Thus, reduced pyridine nucleotide could readily account for nearly all the fluorescence of the *Nebenkern* This confirms observations of suspensions of liver mitochondria in which complete oxidation of intramitochondrial pyridine nucleotide removes the bulk of fluorescence that is excited in the wave-length region 340–366 mμ (ref 2)

The fact that fluorescence of the *Nebenkern* is considerably less than that of the cytoplasm in the aerobic cell and increases to a value considerably greater than in the anaerobic cell is also significant Since pyridine nucleotide is present in the cytoplasm, and may well be bound to dehydrogenases and hence have shifted and intensified fluorescence, it appears reasonable to attribute the cytoplasmic fluorescence, at least in part, to this substance On this basis we conclude that a change in the oxidation-reduction state of the mitochondrial pyridine nucleotide by a factor >3 has no measurable effect upon that of the cytoplasm this is a demonstration *in vivo* of the phenomenon of impermeability of mitochondria to reduced pyridine nucleotide While this phenomenon has been accepted on the basis of *in vitro* experiments[10], the possibility existed that the impermeability of the mitochondrion may have been acquired during isolation, for example, by its envelopment in the endoplasmic reticulum (ref 11, also personal communication) Within the framework of the assumptions here, we can put forward evidence, at least for the grasshopper spermatid, of the unreactivity of the mitochondrial membrane to cytoplasmic pyridine nucleotide *in vivo* This observation is of considerable importance in the study of metabolic control and in the dynamics of interaction of intracellular bodies[12] In cells that fail to show the extent of mitochondrial aggregation observed in the *Nebenkern*, we are at present unable to give further data on this point

Our thanks are due to Dr R P Perry for advice and criticism, and to Miss Georgann Cullen for assistance in these studies

Absorbancy Measurements on Liver and Kidney Cells

By Dr BO THORELL and Prof BRITTON CHANCE

Department of Pathology, Karolinska Institute, Stockholm, and Johnson Research Foundation,
University of Pennsylvania, Philadelphia, Pennsylvania

IN the multicomponent reaction system of the living cell, the organization and spatial distribution of the different enzymes are of fundamental importance During the past decade, much data have been obtained about the localization of enzymes in various cellular structures A further step towards a more integrated and physiologically adequate picture of the cell functions can be made if these enzyme systems are studied *in situ*

This communication reports the localization and assay of respiratory enzymes (cytochromes) in areas of 1 5μ diameter in the cytoplasm of single, living rat liver and kidney cells under different external conditions as regards the oxygen tension, namely, under aerobic and anaerobic states The analyses were made by recording the specific light absorption (magnitude about 1 per cent) in the Soret wave-length region with the highly sensitive microspectrophotometer outlined in the first communication of this group

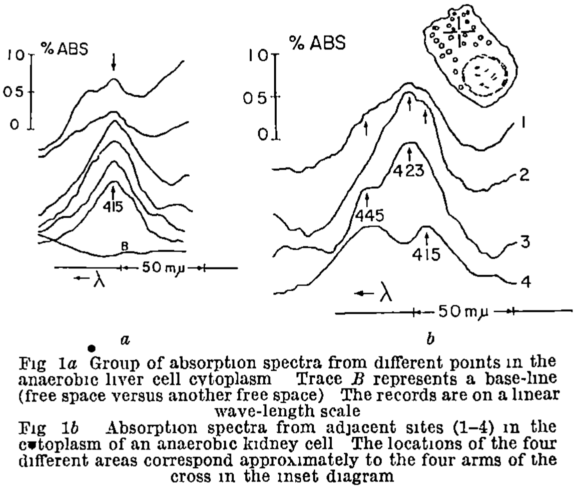
Single parenchyma cells from the liver or kidney-cortex of adult Wistar rats were teased out in a drop of Krebs–Ringer solution on a microscope slide with a small scalpel and a needle After a coverslip had been put on, the cells were washed with a few drops of Krebs–Ringer solution sucked through the preparation by a piece of filter paper To obtain anaerobiosis, ethanol-treated, starved yeast cells were incorporated in the preparation prior to sealing it with paraffin wax around the coverslip edges Without the yeast, aerobic conditions of the cells were obtained for several hours The state of each preparation was checked by measurement of the hæmoglobin absorption bands in some added human erythrocytes[1]

The microspectrophotometer is described in detail elsewhere[2] The microscope optics were a 1 6 mm Grey reflecting water-immersion condenser and 1 0 N A objective A 3 5 × quartz ocular projected the image via a vibrating mirror assembly[1] on to the photomultiplier aperture The location of the cell image on the light-receiving system was controlled by means of an interchangeable cross-hair The areas in the cell selected for absorption measurements were 1 5μ in diameter The 'reference area' in the preparation was at a distance of 12μ from the measurement area and care was taken to choose as clear a space as possible to provide 'absolute' spectra

On the light-absorption records obtained, an empirical wave-length calibration was made by tracing the 415-mμ maximum of the erythrocyte oxyhæmoglobin with the identical wave-length scanning speed and time constant as in the other measurements In this way the cytochrome absorption maxima could be estimated within ± 2 mμ

Figs 1*a* and *b* show typical sets of absorption curves from points in the cytoplasm of single liver and kidney cells, where the anaerobic state was ensured by the presence of respiring yeast cells In the various curves three distinctive absorption maxima or 'shoulders' appear at 415, 423 and 445 mμ

If the yeast cells were omitted and the density of the rat parenchyma cells was low enough to permit the aerobic state during several hours, the changes in the state of the respiratory enzymes could be



a *b*

Fig 1*a* Group of absorption spectra from different points in the anaerobic liver cell cytoplasm Trace *B* represents a base-line (free space versus another free space) The records are on a linear wave-length scale

Fig 1*b* Absorption spectra from adjacent sites (1–4) in the cytoplasm of an anaerobic kidney cell The locations of the four different areas correspond approximately to the four arms of the cross in the inset diagram

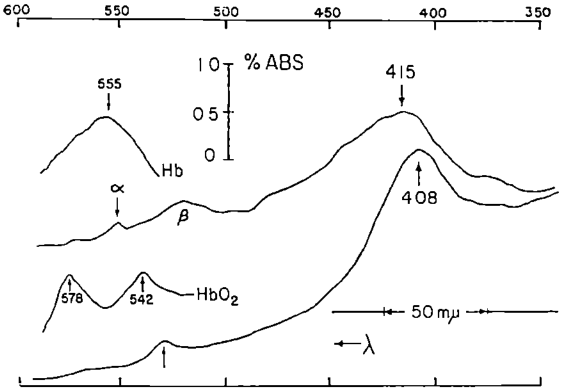


Fig. 2. Spectra from an area of 1·5μ diameter in a liver-cell cytoplasm during the aerobic (bottom record) and subsequent anaerobic (top record) states. The second spectrum was recorded after an interval of 30 min., during which the hæmoglobin absorption of an adjacent human erythrocyte shifted as shown by the two left-hand records

recorded within the same, single cell. Fig. 2 shows such an experiment, in which the hæmoglobin absorption of an adjacent erythrocyte was also recorded. The reduction of the red cell hæmoglobin, which in this particular experiment preceded by about 20 min. the absorption changes in the intracellular cytochromes, indicated that the oxygen concentration in the medium was less than 20×10^{-6} mole per litre.

The results show that absorption bands of the hæmoprotein type can be obtained from small areas ($d = 1·5\mu$) in the single intact mammalian cell. The shift in the absorption maxima which occurred parallel with changes in the oxygen tension indicates that the specific absorptions are due to respiratory enzymes. The orders of magnitude of the absorptions measured in the single liver cell (about 1 per cent) are the same as can be calculated theoretically for cytochromes[3,4].

If the spectra obtained from the single intact cells are compared with the spectra of purified cytochromes, the main peaks at 408_{ox} and 415_{red}, 423_{red} and 445_{red} will correspond to the Soret absorption bands of cytochrome *c*, *b* and *a* respectively.

The strictly quantitative interpretation of the absorption spectra from such optically inhomogeneous materials as liver and kidney cells is more difficult than in the case of the geometrically uniform *Nebenkern* (see first communication). The obviously multicomponent curves in Fig. 1*b* were obtained within a very small optical cross-sectional area (about $2 \times 1·5\mu^2$). The different proportions of the components found at adjacent sites can be explained either by the presence of structures containing varying proportions of cytochromes, or by changes in the layering of a few distinct structures along the microspectrophotometric light-path through the cell.

If the present *in vivo* microspectrophotometric results are compared with the data on enzyme distribution obtained from the bulk isolation of cellular components, some apparently contradictory points emerge. The rather pronounced absorption band 408_{ox}–415_{red} in practically every part of the liver cell cytoplasm indicates large amounts of a cytochrome unlike b_5. The same absorption bands are also present in the large particle-free homogeneous cytoplasmic area ('endoplasm') of the ultra-centrifuged but otherwise intact liver cell[5]. Cytochrome b_5, which can be isolated from the 'microsomal' liver-cell fraction, has bands (413_{ox}–423_{red})[3]. Different explanations for this discrepancy can be put forward: for example, that the isolated 'microsomal' fraction might constitute only a minor part of the 'endoplasm' and that a cytochrome might have been lost during the isolation procedure. Some support for the existence of a difference between the spectral character of the DPNH-reducible pigments and that of the isolated microsomes is emerging from studies of suspensions of liver cells (Chance and Rutter, unpublished observations). In any event, the studies reported here underline the importance of structural interpretations of absorption spectra obtained microspectrophotometrically from the highly complex enzyme system of the living cell.

The main conclusion emerging from the results described is that it is possible to analyse components of the respiratory system and to define the metabolic state of parts of the single intact mammalian cell.

CELL AND ORGAN CULTURE

TECHNIQUES of cell cultivation are being increasingly applied in all fields of biological research. Recent developments in these methods and in their application to cancer research were described by four speakers at a session of Section I (Physiology and Biochemistry) of the recent British Association meeting at York. Cell and organ culture techniques make possible the rapid proliferation of animal and human cells outside the body, and the maintenance *in vitro* of small organs or sections of organs in a healthy condition. It was appropriate that the chairman on this occasion was Dr. E. N. Willmer, one of the leading authorities on tissue culture techniques and research in the United Kingdom.

The first paper was concerned with recent technical advances in cell culture and was given by Dr. J. Paul (HERT Tissue Culture Laboratory, University of Glasgow). As Dr. Paul explained, tissue culture really began fifty years ago with Dr. Ross Harrison's demonstration that axons would grow out of nerve cells cultivated on frog lymph. Although the principles of the technique were at that time clearly stated, only a few biologists followed up this work with enthusiasm and success. One of the common objections to tissue culture in its first years was that the cells which grew were 'neither one thing nor another'. When tissues were explanted in a way which encouraged the rapid multiplication of cells, the organized pattern of the organ was destroyed and the cells which appeared could only be classified in most cases as either fibroblastic or epithelial. If the original morphology was retained, the cells developed abnormal features and deteriorated too rapidly for useful investigations to be undertaken. An outstanding achievement in the pioneer phase was the demonstration in Alexis Carrel's laboratory that avian cells could be induced to multiply indefinitely. This particular cell strain lasted for thirty years—several times the life-span of the fowl—and only died out when there was no one available to keep up the routine feeding and sub-culturing.

Dr. Paul described, with the aid of excellent diagrams, how the mechanization of the technique during the past ten years had led to its increasing use in research laboratories and in the pharmaceutical industry. Although the hard work of developing correct procedures had been done before 1949, the impetus for a rapid advance came from the demonstration by Enders and his colleagues that poliomyelitis virus would multiply in cultures of non-nervous origin. This was followed by the successful use of trypsin for producing suspensions of living cells from body tissues, a technical trick which made easier the large-scale cultivation of cells. Cultures of this type grow in an unorganized manner, and they may, as occasionally happens, produce permanent cell strains. Cells cultured from tumour tissue also grow indefinitely, and these permanent strains of different origin are available to any laboratory for investigations on their nutritional requirements and metabolism, and for virus and cancer research.

Such strains are, of course, specially adapted to grow in culture conditions and, genetically, they may form a most heterogeneous population. Another technical advance which opened the way to the study of the genetics of somatic cells was the discovery that single mammalian cells could be induced to multiply and form clones with distinctive features. This was first accomplished by Dr. Katherine Sanford at Bethesda, who developed an ingenious, although tedious, method of cultivating single cells within capillary tubes. Easier methods of cloning cells from permanent strains have since been devised, and the sublines are being used to study, for example, variations in the malignancy of cells and their response to irradiation.

The second paper in the session, by Dr. O. A. Trowell (Medical Research Council Radiobiological Unit, Harwell), was an entertaining account of the principles and practice of organ culture. The aim of this technique is to preserve the normal histology and functioning of the organ cells outside the body. Its success largely depends upon suppressing the outgrowth of cells, the principle originally demonstrated by Dr. Honor Fell in the cultivation of embryonic limb-buds. Dr. Trowell explained that the business of physiology is to find out how the animal body works and that the logical approach is to study the different organs one at a time. This can be done either by observing the behaviour of the organ in the intact animal in various states of bodily activity or by cutting the organ out of the body and studying its behaviour and capabilities under artificial but completely controlled conditions. These approaches are complementary, and his own choice was to study the isolated organ *in vitro*. The outcome of this approach depended upon keeping the tissue alive as long as possible, since there are many physiological and pathological responses of organs which take several days to develop. Dr. Trowell had, therefore, set out to study systematically the conditions which would maintain organ tissue in a healthy condition for a week or more.

The diffusion of oxygen and nutrients into all the cells of the organ culture can only be ensured by using tiny organs 2 mm. in diameter, such as pituitary, thyroid, adrenal, ovary and lymph nodes of rats and mice. With larger organs, it is necessary to cut off 2 mm. sections of tissue. Cultivation by immersion of the tissue in the medium proved unsuccessful because of the low solubility of oxygen, and efficient stirring of the medium only increased cellular damage. The oxygenation problem is solved by allowing the organ cultures to project into the gas phase. The tissues are, consequently, supported on a stainless steel grid, covered with fine tissue paper which is level with the surface of the medium. The grid, in its shallow dish, is kept in an atmosphere of oxygen at body temperature inside a sterile aluminium container. With this apparatus, many organs can be kept alive for as long as nine days; each 1 in. square grid can carry up to twenty cultures, and the medium can be sucked off and replaced without disturbing the tissues. Culture conditions are completely standardized by the use of a chemically defined medium.

Larger organ cultures would be an advantage, and Dr. Trowell hopes to achieve this by using tissue from horses and cows which have 'built into' their cells a much lower oxygen consumption and metabolism than is found in the cells from rats and mice. Cultures of cow tissue have shown that this is a feasible way of overcoming the limiting effect of oxygen diffusion. By adopting a 'mixed grill' technique, different organs, for example, endocrine organs and their target tissues, can be cultured in the same vessel, and their histology can be correlated with metabolic effects revealed by the changing composition of the medium.

The two remaining papers were concerned with the application of cell and organ culture in cancer research. Scientists and laymen who are still not convinced of the connexion between lung cancer and cigarette smoking ask for direct proof of the causal relationship. For the most sceptical, it is not sufficient to show, as has been done, that cigarette tar and the carcinogens it contains produce tumours in experimental animals; the only acceptable proof is that they induce malignancy in human lung cells. The organ culture technique used by Dr. Ilse Lasnitski (Strangeways Research Laboratory, Cambridge) provides the most direct experimental approach possible. Dr. Lasnitski described how she prepared lung cultures from human fœtal tissue and how the explants would, under normal conditions, show the characteristic formation of bronchioli *in vitro*. The normal histology of these lung cultures and the abnormal changes produced by 3,4-benzpyrene and three types of cigarette smoke condensate in the medium were beautifully illustrated by microphotographs of stained sections of the tissue. Two or three days of exposure to the carcinogen stimulated division of the epithelial cells, and in some sections taken from cultures about three weeks later cell proliferation had completely obliterated the lumen of the bronchioli. During the early stages the normal ciliary and secretory activity of the epithelium was intensified by the carcinogen, but later the cells lost the characteristic features of bronchial epithelium. Occasionally, cells with abnormal mitotic chromosomes were found in the treated cultures. Dr. Lasnitski made it clear that there is, as yet, no proof that cancerous cells had been produced in these experiments. The changes observed might be precancerous, but proof of malignancy would only be obtained if treated cultures would produce tumour-like growth after hetero-transplantation into experimental animals

The usefulness of organ culture was further illustrated by Dr Lasnitski's research on another form of cancer Malignancy of the prostate gland in men is one of the hazards of old age and it is of particular interest to the investigator that this type of cancer can temporarily be controlled by treatment with female sex hormones Cultures of mouse prostate gland were exposed to a chemical carcinogen, this time 20-methylcholanthrene, and again the epithelium of the alveoli became hyperplastic and produced a histology similar to that of skin Dividing cells with polyploid chromosomes were frequently seen in the cultures As in cases of human tumours, the cell proliferation was dependent upon the hormone, since the hyperplastic action of the carcinogen was abolished by the presence of œstrone in the medium and preserved by the male hormone, testosterone Dr Lasnitski concluded by describing briefly investigations on the metabolism of these cultures Autoradiographic studies, undertaken with Dr S R Pelc, showed that the carcinogen stimulated deoxyribonucleic acid synthesis in the epithelial cells, but inhibited deoxyribonucleic acid synthesis by fibroblasts after 2–8 days treatment Amino-acid uptake from the medium was investigated in collaboration with Dr J A Lucy and it was found that leucine and *iso*-leucine were well utilized by normal and treated cultures However, the uptake of arginine associated with normal cultures was decreased after a period of exposure to methylcholanthrene

In the fourth paper, Dr I Leslie (Department of Biochemistry, Queen's University, Belfast) described the search for metabolic features which distinguish normal and cancer cells, and the opportunities provided by cell culture for tackling this problem Three cell types are being studied in Belfast Normal cells are represented by short-term cultures of human fœtal tissues, and malignant cells by the *HEP* 1 strain, derived from a human carcinoma at the Sloan-Kettering Institute for Cancer Research, New York The *HLM* strain came from liver cell cultures prepared from a human fœtus in 1956 Unlike the other cells grown from this fœtus, the *HLM* cells grow indefinitely in culture and, in this respect, they resemble the *HEP* 1 carcinoma cells This 'transformation' of normal cells to an apparently 'immortal' form is not uncommon in cell culture and the process is open to investigation It is important to find how far transformed cells resemble cancer cells and how far they retain the properties of the parent cells The way in which these cells derive their energy from glucose was investigated in 1956 in collaboration with Drs W C Fulton and R Sinclair According to Warburg's original concept, the unique property of malignant cells is their ability to grow by means of the energy of fermentation, that is to say, the enzymic conversion of glucose to lactic acid During proliferation in cell cultures, however, the normal (fœtal) cells showed more intensive fermentation than the carcinoma or the transformed *HLM* cells Other investigators have reported similar results, and Warburg's recent studies on monolayer cultures of monkey kidney cells have caused him to change fundamentally his emphasis on fermentation as the essential feature of malignancy

The explanation of cancer has, therefore, to be sought elsewhere in the metabolism of the cell Since 1953, when Watson and Crick first described the deoxyribonucleic acid molecule and its process of replication, knowledge of cellular physiology has been progressing rapidly As a working basis, Dr Leslie suggested that cancer metabolism can be defined in terms of the biochemical events which lead to the continued replication of deoxyribonucleic acid and which are out of control of the normal restraints imposed by the adult organism It is necessary to study the metabolic events leading to deoxyribonucleic acid synthesis, and to find which are essentially different in normal and cancer cells

Four possible defects in cancer cells were discussed and illustrated by observations on cell cultures The defects were abnormal chromosomes producing modified cell proteins , the channelling of compounds into the synthesis of nucleic acids , the deletion of enzymes controlling the degradation of nucleic acids and proteins , and the loss of control over growth because of the altered response of cancer cells to hormones Evidence for enzyme deletion as a vital defect has come principally from biochemical investigations on liver tumours at the McArdle Memorial Laboratory, Madison, and the Montreal Cancer Institute Now, the absence of xanthine oxidase and arginase in both transformed and carcinoma cells is an example of this type of defect in permanent cell strains The failure of the *HEP* 1 cells of cervical origin to respond to œstradiol (although they respond to insulin) is possibly linked to the recent discoveries by American groups that œstradiol is the co-factor for a transhydrogenase system, and that this enzyme is much reduced in certain tumours It would, however, be wrong to suppose that there is one vital defect common to all tumours The encouraging features of current research are that the key problems in tumour metabolism can be clearly specified and that the techniques for solving them are available

I LESLIE

OBITUARY

Prof F. S. Bodenheimer

FREDERICK SIMON BODENHEIMER, who died in a London hospital on October 4 from internal complications after a successful eye operation, was born in Cologne on June 6, 1897, son of Max Bodenheimer, one of the founders of the Zionist movement As a schoolboy, he was attracted to biology, but was persuaded to study medicine, which offered a more certain future, at Frankfurt and Bonn His main interest was, however, still in zoology, and he obtained his Ph D at Bonn in 1921 with the intention of specializing in entomology and going to Palestine to work there He studied at the School of Agriculture in Geisenheim, and after spending half a year at Portici with Silvestri and Grandi, accepted an appointment as entomologist in the new agricultural research station of the Jewish Agency at Tel Aviv, where he worked during 1922–28

His studies during that period were concentrated on economic entomology, culminating in a book, "Die Schadlingsfauna Palastinas" (1930), but his interests were wider and his energy so inexhaustible that he succeeded, at the same time, in producing two volumes of the "Materialien zur Geschichte der Entomologie" (1928–29) and in carrying out an expedition to the Sinai with Dr. O. Theodor to settle the problem of the origin of manna, which proved to be the excretion of a coccid (*Najacoccus serpentinus*) on tamarisk. In 1928, he was appointed a Research Fellow, and in 1931 professor of zoology at the newly founded Hebrew University at Jerusalem. This opened a period of most fruitful research on a variety of biological problems, resulting in a long series of publications, the total of which during his life exceeded four hundred, including a number of books; apart from those already mentioned, he published "Animal Life in Palestine" (1935), "Prodromus Faunae Palaestinae" (1937), "Problems of Animal Ecology" (1938), "Animals in the Bible Lands" (1949, 1956), "Citrus Entomology in the Middle East" (1951), "Insects as Human Food" (1951), "The History of Biology" (1958), and "Animal Ecology To-day" (1958). His last book, just published, "A Biologist in Israel", is an extensive autobiography, and, at the same time, as he described it to me, "a history of a generation of ecologists".

Bodenheimer travelled extensively; in 1931, after a term as a visiting professor at Minneapolis, he went around the world, stopping where he would; during 1938–41 he was a visiting professor at Ankara and played a prominent part in developing entomological work in Turkey; in 1943 he was invited to Iraq to study the locust problem there; in 1955 he lectured in the University of Durham on Canon H. B. Tristram and visited Finland; in 1956 he went to Australia for a Unesco meeting on the Climatology of Arid Zones and took in South Africa *en route*. Wherever he went, he lost no opportunities of learning at first hand all that could be learned of local biological problems and institutions and workers.

His main life-interest was animal ecology in the broadest sense. His earlier published books on the subject did not receive sufficient recognition, since he had to write in English, which was not his own language, and many of his original ideas have been offered in a not easily digestible form. Moreover, he was never easily satisfied with formal definitions of concepts and always searched for other than the accepted solutions of such basic problems as the equilibrium in animal populations, animal communities, the interaction of environment and heredity, etc. On many of these points he was outspokenly critical of views of others, but his criticisms were always such as not to annoy, but to stimulate.

As an entomologist, Bodenheimer left a great heritage, but he was also well known to mammalogists for his studies on the vole (*Microtus*) populations in Palestine, and before his death he prepared a revision of Canon Tristram's work on the mammals of Palestine.

His many travels and his deep interest in the work of others have made Bodenheimer well known to a large number of biologists all over the world and his early death will be deeply regretted by many. His wife, Mrs. Rachel Bodenheimer, who accompanied him on many of his travels, made friends wherever she went. Their many friends will share her feeling of loss.

B. P. Uvarov

NEWS and VIEWS

Chief Scientist of the Ministry of Supply: Dr. R. Cockburn, C.B., O.B.E.

On October 1, Dr. Robert Cockburn took up the post of chief scientist of the Ministry of Supply. Cockburn gained his first degree at the University of London when he was only nineteen, adding to it later both the M.Sc. and the Ph.D. From 1930 he taught science at the West Ham Municipal College, and at the same time conducted research on the effects of electron transit time in very high-frequency oscillators, until, in 1937, he joined the Radio Department of the Royal Aircraft Establishment, Farnborough, where he was engaged in the development of a new very high-frequency communication system for the Royal Air Force. From 1939 until 1945 Cockburn was at the Telecommunications Research Establishment, Malvern, where he and his team developed and used radio counter-measures of all kinds in the protection both of targets in Britain and British bombers operating over enemy territory. For his outstanding work he was appointed O.B.E. in 1946. He spent a short period at Chalk River and at Harwell, until in 1948 he became scientific adviser to the Air Ministry. He stayed there for five years, joining the Ministry of Supply in 1953, where he has been successively responsible for research and forward thinking in all applications of electronics, for the organization of all the research and development programmes in this field, and since 1956, as controller of guided weapons and electronics, for the whole field of research, development and production of these equipments.

Cockburn brings to his new post exceptional practical knowledge of the operational use and technical requirements of systems that he gained in the Second World War, the intimate knowledge of the Services that he acquired when at the Air Ministry, and the inside knowledge of the Ministry of Supply gathered in the three senior appointments that he has already held there. He adds these to his wide basic scientific knowledge and his international standing and prestige as a scientist who has concentrated on the special problems of defence. His appointment is warmly welcomed by his professional colleagues, Service and scientific, throughout the many circles in which he is well known.

Engineering at Leicester: Prof. E. W. Parkes

Dr. E. W. Parkes has been appointed to the new chair of engineering in the University of Leicester. Dr. Parkes was born at Sutton Coldfield in 1926, and was educated at King Edward's School and St. John's College, Cambridge, where he gained first-class honours in the mechanical sciences tripos in 1945. After leaving Cambridge, he worked for a year at the Royal Aircraft Establishment and for two years with the Hawker Siddeley group on the design and testing of aircraft structures. He returned to

Cambridge in 1948 to study the elastic stresses in flanged beams. In 1950 he was appointed University demonstrator and afterwards lecturer. He was elected into a fellowship at Gonville and Caius College in 1954, and in 1957 was appointed tutor. Dr. Parkes's main fields of research are the inelastic dynamic behaviour of structures and the behaviour of structures subjected to temperature variation. He is particularly interested in repeated thermal loading phenomena such as incremental collapse under thermal cycling. In the industrial field, Dr. Parkes has acted as consultant on the design of crane jibs, tall towers, bridges, boilers and vacuum vessels. He has lectured on his work on thermal stresses on a number of occasions in Denmark and Sweden and is at present spending six months as visiting professor at Stanford University, California, working in the same field.

Highway and Traffic Engineering at Birmingham

Prof. J. Kolbuszewski

DR. J. KOLBUSZEWSKI, who has been appointed to the chair of highway and traffic engineering which has recently been established within the Department of Civil Engineering at the University of Birmingham, joined the University as a lecturer in 1951, the title of reader in soil mechanics being conferred on him in 1957. During the past three years he has been in charge of the Graduate School of Highway Engineering and the Graduate School of Foundation Engineering. Originally, Dr. Kolbuszewski graduated from the University of Lwow, where he was afterwards a lecturer in civil engineering. He served throughout the Second World War with the Polish, French and British armies. After the War he studied at the Imperial College, London, where he obtained his Ph.D. degree. He was a member of the staff of the Polish University College, London, from 1946 to 1950, joining as a lecturer and being promoted to professor and director of studies in 1947.

Dr. Kolbuszewski's research interests have been principally concerned with problems in soil mechanics and foundation engineering, and, in particular, with problems arising in connexion with pressures under pavements and the trafficability of beaches. A few years ago he carried out some original experiments in the Sahara Desert, when he obtained some interesting information regarding the bearing capacity of wind-deposited sands.

Radiation Protection

THE occupational hazards associated with radioactive materials have for a generation been under periodic review by the International Commission on Radiological Protection, which is a commission set up by the International Congress of Radiology and by national bodies. In the United States this is the National Committee on Radiation Protection, which issued its latest report on June 5 (U.S. Department of Commerce: National Bureau of Standards Handbook 69: Maximum Permissible Body Burdens and Maximum Permissible Concentrations of Radionuclides in Air and in Water for Occupational Exposure. Pp. viii+95. Washington, D.C.: Government Printing Office, 1959. 35 cents). The chairman of the sub-committee responsible for this report is also chairman of the corresponding international committee. It can therefore be taken that this document is in many respects a pre-view and abbreviated version of the corresponding recommendations of the International Commission on Radiological Protection which are now in press.

Previous figures for permissible body burdens of radioactive nuclides were given in 1953. The basis for recommendations concerning permissible exposure was revised recently (Recommendations of the International Commission on Radiological Protection, September 9, 1958. Pergamon Press, London, 1959). This has led to corresponding revision to smaller permissible body burdens only for nuclides which result in irradiation to the whole body. However, new biological data and improved methods of calculating physical doses have led to a complete re-assessment of values. This has allowed permissible figures for some nuclides to be increased; notably twice as much strontium-90 as before is now allowed. At the time this produced a furore in the American daily press. On strictly logical grounds the committee could have raised the value five-fold. That it did not do so indicates that judgment and opinion as well as numbers have been used rather than strict logic. After all, the figures are not magical; they are still capable of revision in the light of further information and experience after a further quinquennium.

International Council of Scientific Unions

THE financial statement of the International Council of Scientific Unions for the period November 1, 1957, to December 31, 1958 (pp. 12. The Hague: International Council of Scientific Unions, 1959), records an excess of expenditure over income for the period of 16,638 dollars, in spite of a further increase in the income from member unions to 2,852 dollars. The 67,428 dollars received from national members during the year includes 20,898 dollars, representing annual dues previously in arrear. The increase in expenditure from 42,970 dollars in 1956–57 to 88,139 dollars is attributed to the increasing scientific activity of the Council, the higher costs of running the Secretariat, mainly due to increased staff, the heavy costs of holding the 1958 General Assembly and Meeting of the Executive Board in the United States and the establishment of a Secretariat in The Hague, apart from the fact that running expenses are for fourteen months instead of the normal twelve. For the triennium 1959–61 the eighth General Assembly adopted a budget of 58,000 dollars per annum, and the Assembly also strongly endorsed the decision of the Executive Board to establish a capital fund.

University Foundation of Belgium

DURING the academic year 1957–58 the University Foundation of Belgium distributed subsidies totalling 4,858,992 francs and 2,441,500 francs in awards for ordinary studies. Of the latter, 1,046,500 francs were at the University of Louvain, 718,000 francs at the University of Ghent, 359,000 francs at the University of Brussels and 198,500 at the University of Liège. Of the 167 awards, 32 were in science, 4 in pharmacy, 33 in medicine, 1 in veterinary medicine, 3 in dental science, 32 in engineering, 4 in agronomy, 5 in political, social or administrative science, 5 in commercial or economic science or finance, and 4 in applied psychology and vocational guidance. Five awards were made for courses of study abroad: four in France and one in Switzerland. Subsidies for the publication of scientific works amounted to 458,500 francs and to periodicals to 2,158,000 francs, while scientific associations received subsidies amounting to 606,000 francs The thirty-eighth annual report of the Foundation (Fondation Universitaire Trente-huitième Rapport Annuel, 1957–1958 Pp 148 Bruxelles Fondation Universitaire, 1959) which gives these figures, includes a list of beneficiaries during the year, as well as some notes on institutions with which the Foundation has connexions It also includes a list of bursars for 1958–59 under the Belgian American Education Foundation, Inc , both in Belgium and in America Of the 29,651 university students enrolled in 1957–58, 81 5 per cent were men and 18 5 per cent women 11 35 per cent were in science, 25 33 per cent in medicine and pharmacy, 11 62 per cent in applied science, 2 52 per cent in agronomy, 6 15 per cent in social, political and economic science, and 13 16 per cent in commercial science Of 4,770 diplomas obtained in 1956–57, 630 were in science, 1,035 in medicine and pharmacy, 33 in veterinary medicine, 405 in applied science, 151 in agronomy, 266 in social, political and economic science, and 654 in commercial science

Industrial Psychology Grant Increased

The Department of Scientific and Industrial Research is to continue its annual grant to the National Institute of Industrial Psychology for a further five years The amount is to be raised from £4,000 to £6,000 a year, on the understanding that the Institute will increase to £9,000 a year its own income from membership subscriptions and special contributions for long-term research The Department of Scientific and Industrial Research is also to add another £100 a year for every £100 of grant-earning income which the Institute can obtain in excess of the qualifying £9,000, up to a maximum of another £6,000 a year This means that if the Institute can raise £15,000 a year from industry, the Government will give it £12,000 The grant and the grant-earning income have to be put in a special fund and used only for long-term research. Among research projects now in train are an inquiry into workers' attitudes to the opportunities and rewards offered by their jobs which may have a bearing on personnel policies ; an investigation into the relation between satisfaction and efficiency on the job , a study of industrial management structure and efficiency , and experiments on tests for manual skill The Institute has received many inquiries from industry recently about the special tests it has devised for selecting suitable school-leavers to be engineering apprentices

Australian Atomic Energy Commission Research Grants

Research grants totalling almost £28,000 have recently been awarded by the Australian Atomic Energy Commission in support of research under contract in seven Australian universities Fields covered include chemistry, physics, geology, mining, electrical, metallurgical and chemical engineering, and the biological sciences The grants have been made for work in fields which will contribute to the Commission's own work in developing civilian uses of atomic energy

Alkali and Similar Works in Britain

The ninety-fifth report of the Chief Inspector on Alkali, etc , Works in England and Wales covering the year 1958 notes an increase in the number of works registered under the Act from 872 at the end of 1957 to 2,160 at the end of 1958 It also shows an increase in the number of separate processes from 1,733 to 3,412 in consequence of the extensions of the list of scheduled works and of noxious or offensive gases under the Alkali, etc , Works Order, 1958 Many of the new registrations relate to very large undertakings, particularly as regards the iron and steel industry and the newer electric power stations The result of these increases is that the staff of the inspectorate has been increased, and it will now be necessary to adjust the internal organization The 7,142 visits and inspections during the year included 255 special visits by the chief and deputy chief inspectors and 32 by Mr W A Damon, the former chief inspector, who continues to serve in a special advisory capacity Several visits were again paid to establishments of the Atomic Energy Authority, and discussions with the Authority during 1958 covered problems arising out of the nuclear power problem, particularly as regards the increased scale of processing uranium for use as a fuel and of irradiated uranium from the projected nuclear power installations Considerable interest has been shown by local authorities in clean air matters and in the processes scheduled by the 1958 Order, and friendly and adequate liaison and co-operation appear to have been established There were twelve infractions of pre-1958 processes compared with seventeen in 1958, and of these, six related to escapes of acid gases in excess of statutory limits and six to failure to use 'best practicable means' The Chief Inspector for Scotland reports 213 visits during the year, including 27 in connexion with the Alkali, etc , Works (Scotland) Order, 1958, mainly about points of doubt in applications to register In the course of 89 chemical tests, three infringements were found, two in chamber sulphuric acid plants, which appeared to be quite inadvertent, and one at a plant for concentrating sulphuric acid Two further infringements were noted during visual inspection of premises registered for distillation of tar

New Journal of Psychopharmacology

Literature on psychopharmacology has hitherto either appeared as contributions to symposia, of which the past years have seen ever-increasing numbers, or been scattered in the periodicals of many disciplines, such as psychology, psychiatry, physiology, biochemistry and pharmacology *Psychopharmacologia* is a new journal aiming at finding a single home for the investigations on the effect of drugs on behaviour carried out by workers with the greatest variety of training (Vol 1, Fasc 1 Pp 78+10 9 60 D M Maximal-preis 1959, 40 D M Maximal-preis 1960, 80 D M Berlin Springer-Verlag, 1959) There will be some overlap with the recently launched periodical *Biochemical Pharmacology* as there will be with the *Journal of Neurochemistry*, but interest in this field has been so great in recent years that the editors will experience little difficulty in obtaining manuscripts of the highest standard Papers will be accepted in English, French or German The advisory board is recruited from Western Europe and North America The first number contains a review and a number of original articles and makes interesting reading It is to be hoped that psychopharmacologists, while keeping up with their own discipline, will find time to read yet another integrating journal

Bird Paintings of the Eighteenth Century

The Trustees of the British Museum have published an account of "Some Eighteenth Century Bird Paintings in the Library of Sir Joseph Banks (1743–1820)", by Averil Lysaght (*Bull. Brit. Mus. (Nat. Hist.)*, Historical Series, 1, No. 6. Pp. 251–371+plates 35–37. From the Museum. 40*s*.) This collection, ultimately passing to the British Museum, included the work of various artists accompanying Captain Cook on his three voyages. These are of interest to systematists in that some of the drawings rank as the types of the then newly discovered species, the actual specimens having deteriorated or perished. The record is of all the more value in that some of the species have meanwhile become greatly reduced in numbers and geographical incidence, if not extinct. Owing to the accident that some of the illustrations remained in Bloomsbury when others were transferred to South Kensington in 1880, these were overlooked by Bowdler Sharpe and others. The task of making a new assessment was originally suggested by the late Sir Norman Kinnear.

Microcard Adapter for 'Dagmar' Microfilm Reader

The Dutch 'Dagmar' microfilm-microfiche reader, which was introduced into Great Britain in 1957, has proved itself to be a good, cheap, portable reader with many attractive features. It has been made even more versatile by the addition of a microcard adapter. This has been developed in the library of the Manchester College of Science and Technology and it is now being manufactured for sale to others. Anyone already owning a 'Dagmar' can effect the alteration necessary to take the adapter in a few moments. A small hole has to be cut in the front panel above the lens and a triangular casting bolted on. This takes the condenser system of the adapter and positions the illumination so that it shines down on to the microcard which is in the glass microfiche holder. The adapter is being distributed by Trew Microfilming, Ltd., 22 Park Lane, Croydon, at about £19.

Museum of Applied Science, Victoria

Those engaged in museum work have often deplored the name but have failed to find an adequate substitute. The Report of the Museum of Applied Science for the year ended June 1958 states that the Trustees have unanimously recommended that the term 'Institute' shall replace 'Museum', and they trust that the necessary legislation to effect the change shall be introduced. It is felt that the new title will indicate more clearly the present functions and activities, especially as the displays interpret the rapid and continuing advances in applied science and technology. The International Geophysical Year was well publicized both by means of special displays and booklets.

Cancer Current Literature Index

The Excerpta Medica Foundation, which has its main office in Amsterdam, provides a monthly comprehensive series of abstracts on branches of medicine, one of which is devoted to cancer. The August issue of the cancer section is a sizeable volume of 170 pages containing nearly 600 abstracts. The Foundation has now, in collaboration with the U.S. Cancer Society, begun the production of a still more condensed form of abstracts which consists only of title, author and reference to publication; the first number (September) is a guide to 300 papers, dealing with different aspects of cancer research. The aim of this publication, which has been made possible by a grant from the U.S. Cancer Society, Inc., New York, is to provide a regular, up-to-date index of the bibliographical references to the world's literature in the field of cancer. The "Cancer Current Literature Index" will appear at intervals of two to three weeks. Each yearly volume will contain approximately 4,500 references from some 3,000 medical journals published all over the world, including those from the U.S.S.R.

Cattle and Buffaloes of India

About 20 per cent of the total number of cattle in the world exist in India, and while at present they are mainly used for draught purposes, their potentiality, at present but poorly developed, for milk supply is great. Improvement of these cattle for milk production would not only supply one of the main nutritional needs of the Indian peoples but also would improve the economic position of the peasant farmer by giving him the weekly income which he does not receive from crop farming alone. One of the steps towards an improvement is the holding of cattle shows for the development of special breeds. A bulletin published by the Indian Council of Agricultural Research on "Bovine Stars of India" illustrates some of the best individual cattle of different breeds exhibited at four Regional and the All India Cattle Shows in 1955 (Indian Council of Agricultural Research Misc. Bulletin No. 82. Pp. iv+29. Delhi: Manager of Publications, 1957. Rs. 2.37, 4*s*.) It is stated that some of the cattle have been given prizes for being the best milch type, but the absence of any actual records of production to go with the photographs is to be regretted. Since the buffaloes and native Zebu breeds of cattle have a high degree of heat tolerance it is on their improvement rather than by the introduction of European breeds, lacking heat tolerance, that the future milk supply of India lies. Bulls and cows of some twenty-six breeds of cattle and three breeds of buffaloes have been photographed against a squared background which enables one to judge actual size, and an attempt is to be made to record body measurements at future shows. Some good draught type cattle are also illustrated, but one wonders how long it will be before they are replaced by mechanization.

Pest Control

The Ministry of Agriculture, Fisheries and Food has published under the title "Infestation Control: a Service to Agriculture and Food Storage" (pp. iv+32+12 plates. London: H.M. Stationery Office. 4*s*.) a pamphlet describing the research carried out by its officers on the problems of infestation control in farms and warehouses, together with a brief history of the subject in Great Britain. The work falls into two main parts, one dealing with the insect pests of stored foodstuffs, the other with vertebrate enemies, such as rodents and birds. By what must be regarded as a political accident, vertebrates are covered whether they attack crops in the field or in store, whereas the invertebrate field pests are the responsibility of another section of the Ministry. Both parts of the pamphlet cover a surprisingly wide range of topics in which the application of scientific method has made important contributions to public health or profit. These concern especially the control of insect pests by chemical means and the development of new techniques for baiting rodents and, more recently, the development of anti-coagulant poisons. Perhaps characteristically in Britain, the pioneer work was done in the universities and received final Government blessing during the Second World War. There is a useful list of papers published by members of the infestation control division during the past fifteen years.

Nitrogen Replenishment in the Soil

LAND fertility improvement was the theme of the presidential address by Dr. N. R. Dhar, of the University of Allahabad, this year to the Indian Society of Soil Science held at Delhi. He points out that the amount of fertilizer used in the world is still very inadequate and production of nitrogen fertilizer appears to be lagging behind production of phosphate and potash. Under-developed countries are poorly equipped with nitrogen-fixation factories because of the high capital investment involved. Dhar estimates that approximately one hundred million tons of fixed nitrogen is necessary for the food supply of the world, but present production is less than eight million tons. This emphasizes the importance of other nitrogen sources. For example, legumes probably fix five million tons of nitrogen and rain contains about ten million tons. It is also pointed out that the amount of nitrogen lost in refuse from urban areas is about equivalent to the amount of nitrogen supplied to world crops as fertilizer. Even in highly organized agriculture such as in the United States, more nitrogen is removed from the soil than returned as fertilizer, resulting in an annual deficit of six million tons. This translated into world figures means a loss of about fifty million tons of nitrogen a year. This annual loss must be compensated in permanent agriculture by natural methods of recuperation. By making assumptions concerning the amount of carbon added to the earth by photosynthesis and the proportion of this which in turn is oxidized, it is estimated that one hundred and ten million tons of nitrogen a year is fixed by natural processes. Hence this is the chief natural source of soil nitrogen and far exceeds the amount supplied by fertilizers.

Tectonics in the U.S.S.R.

A GREAT advance in tectonics was made by the publication of the tectonic map of the Soviet Union in 1957 on the scale of 1:5,000,000, published on nine sheets. This map is coloured vividly in accordance with the orogenic age of the formations, with tints and shadings indicating various folding phases and structural features. The map was compiled by a number of geologists under the direction of N. S. Shatsky, one of the foremost tectonists in the Soviet Union. It was accompanied by an explanatory memoir written by N. S. Shatsky and A. A. Bogdanov. A small-sized variant of this map is published by Y. A. Kosygin (*Priroda*, 8, 21; 1958) as an illustration for his article dealing with new methods applied to the study of tectonic structure of the Earth's crust by means of deep stratigraphical boreholes. This method, according to the author, is particularly suitable for the study of the 'cover' of ancient 'platforms' and also for the preparation of 'palæogeological' maps of the 'floor' of the 'cover'. In another article Y. A. Meshcheryakov (*Priroda*, 9, 15; 1958) discusses 'neotectonics'—a term proposed by V. A. Obruchev for the study of the recent or near-recent movements of the Earth's crust. In this article he gives a 'neotectonic' map of the European part of the Soviet Union and a generalized map of the world showing regions of recent elevation and depression as well as the earthquakes zones. This map shows that the modern regions of elevation are not confined to the areas of Quaternary glaciation and therefore cannot be explained by the hypothesis of glacial isostasy control.

Meteorological Data

RADAR is a powerful tool for the meteorologist in the detection of precipitation as it is the only means of locating the positions of all precipitation falling at above a certain moderate rate and at any one time within a distance of the order of 100 miles from the transmitter. The strength of the radar echo is proportional to ND^6/L^4, where N is the number of drops in unit volume, D the drop diameter and L the wave-length of the radar. The echo intensity thus increases very rapidly with the size of the drops. The advantage of a very short wave-length is, however, offset by increased attenuation of the beam by precipitation and the water vapour and oxygen of the air, and by engineering difficulties of obtaining adequate radiant power. In practice, wave-lengths in the region of 3–10 cm. are mostly used, giving admirable representation of moderate and heavy rain at distances up to 100 miles or more. Radar is of great value for guiding aircraft in and out of airfields to avoid highly turbulent thunderclouds, in forecasting the approach to cities of thunderstorms with their effects on public transport and demand for lighting, and also in the study of cloud structure and hydrology. The subject is comprehensively discussed in all its aspects in a recent report by the World Meteorological Organization prepared by a Working Group of the Commission for Instruments and Methods of Observation under the chairmanship of Mr. R. F. Jones, of the Meteorological Office (Technical Note No. 27: Use of Ground-Based Radar in Meteorology (Excluding Upper-Wind Measurements). Pp. xvi+80. Geneva: Secretariat of the World Meteorological Organization, 1959. 9 Swiss francs.) This describes the basic theory, types of radar and display, recording and transmitting the information, the types of radar echo associated with clouds and precipitation, echoes from other phenomena such as smoke, insects and birds, the practical applications and the use of radar in research.

European Nuclear Energy Project, *Dragon*

THREE engineers, one from Switzerland and two from Italy, arrived in Britain on September 21, representing the advance guard of some ninety European engineers and scientists who, with 160 from the United Kingdom, will comprise the international staff of the *Dragon* project of the Organization for European Economic Co-operation at the Atomic Energy Establishment, Winfrith, Dorset (see *Nature*, 183, 507; 1959).

Harwell Reactor School Courses

STANDARD Course No. 20 of the Harwell Reactor School will commence on January 4 and continue until April 29, 1960. These courses, which began in September 1954, are designed to train engineers in the techniques of reactor construction and operation, particularly in connexion with nuclear power stations A special course for senior technical executives, the tenth of its kind, will be held during May 9–20, 1960 Application forms and details of both courses can be obtained from the Principal, Reactor School, Atomic Energy Research Establishment, Harwell, Didcot, Berks

University News : Oxford

It is announced that the Medical Research Council has provided a grant not exceeding £1,100 for the year beginning October 1 for scientific assistance in a study of X-ray analytical methods of insulin and related structures, to be carried out in the Laboratory of Chemical Crystallography under the direction of Dr D M Hodgkin A grant not exceeding £5,700 for the three years beginning October 1 has been provided by the United Kingdom Atomic Energy Authority for studies in interferometric spectroscopy to be carried out in the Clarendon Laboratory under the direction of Dr H G Kuhn, and in addition a further grant not exceeding £1,250 during the period October 1, 1959, to September 30, 1960, for work on the constitution of bismuth-rich alloys being carried out in the Department of Metallurgy under the direction of Prof W Hume-Rothery

The United States Public Health Service has provided a sum of 14,160 dollars for the year which commenced September 1 for the continuation of research on vision and light quanta, being carried out in the Department of Physiology by Dr M H Pirenne, under the direction of Prof E G T Liddell

Grants are to be received from the Department of Scientific and Industrial Research as follows £1,000 for the year beginning October 1, for research on some natural products with biological activity, to be carried out in the Sir William Dunn School of Pathology under the direction of Dr E P Abraham, £1,500 for one year as from October 1, for research into perceptual limitations in high-speed performance, to be carried out in the Institute of Experimental Psychology by Dr H Kay, under the direction of Prof R C Oldfield, £22,860 for the three years ending September 30, 1962, for an investigation of the geological age of rock series by methods based on natural radioactivity, being carried out in the Department of Geology under the direction of Prof L R Wager, £1,220 for equipment for research on the biochemical mechanism of cell division, to be carried out in the Department of Biochemistry under the direction of Sir Hans Krebs, £25,725 for the period October 1, 1959, to July 31, 1962, for an investigation of materials, using magnetic resonance and double resonance techniques, to be carried out in the Clarendon Laboratory under the direction of Prof B Bleaney, £17,610 for the period October 1, 1959, to July 31, 1962, for an investigation of nuclear orientation and nuclear cooling in magnetic fields to be carried out in the Clarendon Laboratory by N Kurti under the direction of Prof B Bleaney The Ministry of Supply has provided a grant not exceeding £1,175 for the year as from September 1, 1959, for the continuation of an investigation of fluorocarbohydrates being carried out in the Department of Biochemistry under the direction of Dr P W Kent £2,200 is to be expended from the University General Fund on alterations to the Department of Zoology in order to provide additional teaching space

Mr F A Burchardt, director of the Institute of Statistics, who died on December 21, 1958, has been succeeded by E F Jackson, Fellow of St Antony's College

World Meeting on Veterinary Education

A world meeting on veterinary education, to be held in London during April 25–29, 1960, is being convened by the Food and Agriculture Organization The meeting will be held at Church House, Westminster, by invitation of H M Government, and will be attended by participants from most parts of the world, including the Far East, Latin America, the Near East and Africa

British Society of Rheology

The British Society of Rheology has announced the following officers for the year 1959–60 *President*, Dr H Kolsky (Armament Design Establishment), *Hon Secretary*, Dr M F Culpin, *Hon Treasurer*, Mr C C Mill, *Hon Editor* (*Bulletin*), Mr J F Hutton (Shell Research, Ltd), and *Hon Editor* (*Abstracts*), Dr J C Vernon

British Electronic Achievements

The scheme for awarding annual premiums for articles on electronics, organized in the past by the Radio Industry Council (London) is now under the joint sponsorship of the Council and of the Electronic Engineering Association Articles published during 1959 will be considered by the panel of judges early in the New Year, and explanatory leaflets can be obtained from the Electronic Engineering Association, 11 Green Street, London, W 1, to which also eligible articles should be submitted before the end of the year

The Annual Review of Pharmacology

Annual Reviews, Inc, of Palo Alto, California, announces the organization of a new series "The Annual Review of Pharmacology". The first volume is scheduled to appear in April 1961 Prof Windsor C Cutting, of Stanford University, has been appointed as editor, and Prof Henry W Elliott, of the University of California, as associate editor Members of the Editorial Committee, under whose direction the Reviews will be organized, are initially as follows Windsor C Cutting (*chairman*), Bernard B Brodie, National Heart Institute, Maynard B Chenoweth, Dow Chemical Co, Louis S Goodman, University of Utah, G B Koelle, University of Pennsylvania, Chauncy D Leake, Ohio State University, and Maurice H Seevers, University of Michigan

Announcements

Mr A Perera, representing Ceylon, has been appointed chairman of the Executive Council of the Commonwealth Agricultural Bureaux, in succession to Dr J G Malloch Mr C K Reheem, representing Pakistan, has succeeded Mr Perera as vice-chairman

Erratum In the communication entitled "Production of Serum Albumin and of Globulins ", by Prof E Broda *et al*, in *Nature* of August 1, p 361, the penultimate line of column 1 should be at the foot of column 2, further, Dr Leslie's strain referred to in column 2 should be *HLM* and not *HIM* as printed

THE EUROPEAN ORGANIZATION FOR NUCLEAR RESEARCH

PRESENT STATUS

THE European Organization for Nuclear Research (CERN) has in operation a synchrocyclotron, accelerating protons to 600 MeV., and is in course of constructing an alternating-gradient synchrotron which is designed to accelerate protons up to 25 GeV. In addition to these two accelerators, CERN is building up on its site at Meyrin, near Geneva, experimental equipment and services comparable with those existing or being built at Brookhaven and Berkeley in the United States and at Dubna in the U.S.S.R.

The synchrocyclotron, which has been running for more than a year and in recent months has operated for 95 per cent of the scheduled time, is yielding an ever-increasing flow of experimental results. Analysed beams of mesons, neutrons and protons are available in two experimental halls on either side of the machine. The most recent experiments which have been completed include a charge-independence experiment concerning the ratio of the cross-sections of the reactions $p + d \rightarrow H^3 + \pi^+$ and $p + d \rightarrow He^3 + \pi^0$, which should be (apart from Coulomb and mass correction) exactly 2. The experimental accuracy achieved was 5 per cent, which is perhaps the most precise confirmation of charge-independence yet obtained at high energies. An experiment in an earlier stage is examining the neutron groups from the reactions $\pi^- + p \rightarrow \pi^0 + n$ and $\pi^- + p \rightarrow \gamma + n$ with 70 MeV. pions. This has already yielded an accurate value of the π^0 mass. Two experiments which are now being designed are on the scattering of μ-mesons by nuclei (for which a focusing channel for muons is under construction) and an experiment for the accurate measurement of the anomalous part of the magnetic moment of the muon. Two experiments using hydrogen bubble chambers are just starting; the first, using a 25 cm. diameter chamber brought to CERN by an Italian group, deals with the scattering of 350 MeV. pions by protons, and the second, using a 30 cm. diameter chamber built at CERN, deals with the double production of π-mesons. Many other experiments are being carried out with the synchrocyclotron by teams of CERN physicists and by visiting groups from the member countries of CERN. About 30 per cent of the running time of the machine is scheduled for these visiting groups, which include teams from Padua, Utrecht, Harwell and University College, London.

The magnet units of the 25 GeV. proton synchrotron, one hundred in number and weighing in total 4,000 tons, are mounted in the machine building, a subterranean annular tunnel covered with 3 m. of earth. Pulsing tests on the magnet, using the rectifier-inverter set and generator, began in the latter part of July. The vacuum system, a 620 m. long elliptic tube pumped by fifty vacuum pumping stations, is nearly assembled, as are the sixteen radio-frequency accelerating stations. Two tanks of the three-tank linear accelerator, which will inject protons with an energy of 50 MeV. into the synchrotron, are working, giving 3.5 m.amp. of 30 MeV. protons.

Considerable thought has gone into the planning of the experimental apparatus to be used with the 25 GeV. accelerator and into the layout of this apparatus in the experimental halls. The largest pieces of equipment being built at CERN are a 2 m. long liquid hydrogen bubble chamber, a 1 m. diameter propane bubble chamber and a 2 m. long gas Čerenkov counter. The propane chamber, complete with its magnet, giving a field in the chamber of 18,000 gauss, weighs about 100 tons and is planned to come into operation in the middle of next year. The hydrogen chamber and its magnet weigh about 600 tons and are scheduled for operation in 1962. A French group from the Centre d'Études Nucléaires, Saclay, will bring an 80 cm. long hydrogen bubble chamber to CERN towards the end of 1960, and a British group plan to bring an even larger hydrogen chamber in 1961. Another French group, from the École Polytechnique, Paris, plans to bring a 1 m. long propane bubble chamber next year. These 'visiting' bubble chambers will be used at CERN by mixed teams of CERN physicists and the physicists coming with the chambers. Initially, the 30 cm. diameter CERN hydrogen bubble chamber will be used for exploratory experiments. To get momentum-analysed and purified beams of particles to these bubble chambers and to counter experiments, systems of bending and focusing magnets have been designed and ordered, and a 30 m. long beam separator is in course of study. Direct current generators, totalling 8 MW. capacity, are being installed to power these experimental magnets.

Although about 500 sq. m. of floor area are at present available for experiments with the proton synchrotron, this space will be fully occupied by experimental equipment within a year or so of the accelerator coming into operation. A new experimental area, foreseen for use in 1962, will provide special buildings for the very large hydrogen bubble chambers and a 600 m. long flight path for the beams of particles emerging from the synchrotron. This long flight path is necessitated by the extreme difficulties encountered in trying to distinguish between different types of particles at such high energies where all particles, irrespective of their rest mass, are travelling at very nearly the velocity of light. It is possible to discriminate between different particles only after they have travelled hundreds of metres, when the small relative velocity differences of the particles have resulted in a time separation which can be measured by electronic discriminators with resolution times of a few nanoseconds (10^{-9} sec.).

The analysis of the bubble chamber photographs will be carried out with semi-automatic measuring machines, designed at CERN, similar to those already in use at the Radiation Laboratory at Berkeley. The output of these machines, in digital form, is fed into the Ferranti *Mercury* computer now in operation at CERN, for spatial reconstruction and kinematic analysis of events.

In addition to the experimental groups using the 600 MeV. synchrocyclotron and planning experiments with the 25 GeV. synchrotron, there is a strong theoretical group established at CERN which not only contributes to pure theory, but also takes an important part in the initial planning of experiments and in the interpretation of the experimental results. Among the problems studied by this group are those of parity conservation in strong and weak interactions, particularly how it is possible to reconcile the violation of parity in strong interactions involving K-mesons with the quasi conservation in nuclear interactions involving π-mesons Another problem being studied relates to the magnetic moment of the μ-meson

Apart from the two accelerators, their experimental programmes and theoretical work, CERN is carrying out a basic research programme on new methods of accelerating particles, the results of which can be used as a basis for future machines and to improve the existing machines The Accelerator Research Group is at present studying intersecting-beam machines that will yield energies in the centre of mass system higher than is practicable with existing machines using targets in which the bombarded nuclei are at rest, very high current machines using beam stacking techniques, and plasma accelerators that can either be used as high-current machines or to provide, by means of very high circulating electron beam currents, intense magnetic guide fields for heavier particles Several experimental plasma betatrons have been built, and an electron beam stacking model is now being planned which will provide a flexible experimental tool for investigating stability problems in high-current beams and in intersecting-beam machines

The total staff of CERN is nearly a thousand, about two hundred of which are physicists and engineers, and in addition to staff appointments CERN offers fellowships to enable physicists from all over the world to participate in the work of the Laboratory About sixty physicists are currently using these fellowships at CERN

THE BRITISH COMPUTER SOCIETY

FIRST CONFERENCE

IN view of the widespread interest in computers nowadays, particularly in the fields of science and engineering, it is perhaps, a little surprising that the British Computer Society should have held only its first conference last June However, as the president, Dr M V Wilkes, reminded us, it was not the first time that a conference of those interested in computing had been held at Cambridge, the last one being almost exactly 10 years previously, when the subject was in its infancy The rapid growth of interest in the subject is instanced by the capacity attendance of 330 at the conference and by the increasing membership of the British Computer Society, which is now more than 2,000, drawn from a wide variety of backgrounds

These differing backgrounds accounted for the considerable range of topics discussed, running from the structure of myoglobin through automatic programming and logical design to the problems of auditing accounts kept by computers The work currently being done by Perutz, Kendrew and others on protein structures would scarcely have been possible without the use of fast computing machinery, and Dr J C Kendrew, in his interesting address, brought out clearly the importance of the existence of, and of further developments in, these powerful tools He described the work recently done on the structure of myoglobin, mainly using X-ray diffraction techniques applied to structures into which a heavy atom had been artificially introduced by chemical methods Photographs of diffraction patterns from single crystals have enabled the broad outlines of the structure to be determined and a model of the polypeptide chain to be built up It is hoped next to determine the detailed atomic positions within the structure by more sophisticated techniques These techniques will involve processing very large amounts of data, some thousands of reflexions being obtained from the X-ray apparatus

All these must be included in the refinement calculations, which result in the tabulation of electron density values over a hundred or more two-dimensional Fourier sections through the crystal, each section involving evaluations at many hundreds of points The processing will thus require not only very rapid calculation facilities, but also adequate supporting equipment for input of data and output of results Furthermore, myoglobin is one of the simpler protein structures, so that future advances in this field will undoubtedly require the fastest and largest equipment available

Developments in very fast computers were described in a crowded session by Drs T Kilburn (Manchester), M Lehmann (Israel), and N C Metropolis (Chicago) Dr Kilburn described the *Muse* project, which is now in an advanced stage of planning, to build a computer at the University of Manchester with speeds of operation in the millimicrosecond range This machine, like most other modern developments, will rely primarily on transistors and magnetic cores as fundamental elements for storage, arithmetic operation, and control The arithmetic unit, a prototype of which has been built and is now being tested, is capable of carrying out multiplications and additions on numbers in floating point representation in less than 2 microseconds, and administrative instructions will be carried out in less than 1/5 μsec The main storage is to be on magnetic cores, with an access time of 2 μsec However, overlapping of operations in some parts of the machine will reduce the effective access to ½ μsec In addition, a special store is also provided from which words can be read in about 1/7 μsec , but into which writing is restricted A wide use of time sharing is to be made in controlling input, output and bulk storage mechanisms, such as magnetic tapes Up to 16 magnetic tapes and, in addition, up to 16 slower mechanisms can be feeding into or be fed by the computer simultaneously, the computer control scanning these units in sequence at a pace sufficiently rapid to allow inspection of each one at a suitable interval

It is hoped that this very powerful machine will be working in just over two years time, and that copies will later be available commercially

Dr Lehmann described a fast but comparatively small computer which is being designed for the Israeli Ministry of Defence This will include an 8,000-word drum and a core store of 128 words, and is expected to be very cheap to produce, although comparable in speed with many of the large machines of to-day, which cost hundreds of thousands of pounds

Dr Metropolis described the computer being developed at the University of Chicago under his direction This machine is to be in the same speed-range as the

Muse, but is not planned, at present, on quite such a large scale. Nevertheless a core store of more than 8,000 words with an access time of 2 µsec is to be provided and there is provision for at least four magnetic tape mechanisms to be attached to the machine. Two very interesting features are the proposed structure of the arithmetic unit and a new method of number representation it is intended to incorporate. The arithmetic unit is to be built on the same principle as that of the *Maniac* at Los Alamos, using asynchronous circuitry, but will include many additional cross-connexions between registers to facilitate rapid arithmetical working. A number representation, called 'significant digit' representation, will be used. This is a form of floating point representation which avoids the appearance of many meaningless digits at the end of approximate numbers, while retaining a few guarding digits against rounding errors.

An important application of fast machines is to problems in supersonic flow-past aerofoils and other surfaces. An interesting contribution to this subject was made by Mr. D. S. Butler of the Armaments Research and Development Establishment who described some recent work he has carried out on this problem.

In order to calculate the lines of flow around and pressures on a solid figure in a supersonic airstream it is necessary to solve a hyperbolic partial differential equation in three variables. He discussed various methods of doing this and made particular reference to the method of characteristics, a powerful technique for solving equations of this type. He went on to describe a particular example of stationary flow around a body shaped like a delta-wing aircraft and showed how the calculations had been carried out in this case using the computer at Fort Halstead, a Ferranti Mk. 1*.

Other topics at the conference which excited considerable interest concerned the control of production in factories and the application of operational research techniques to this and allied problems. Mr. F. Bryen of Imperial Chemical Industries described an application of punched card machinery to factory control, and Mr. J. Harling of Urwick, Orr and Partners dealt very interestingly with the use of computers for operations research. An application of one of the latter techniques within the Shell group of companies formed the subject of a later address by Mr. C. S. Galer. There were also sessions on keeping accounts by computer, on auditing the accounts so kept, on the training and selection of programmers, on automatic programming, and on working experience with magnetic tape mechanisms. On the mathematical side, Dr. A. S. Householder of the Oak Ridge National Laboratory, Tennessee, directed attention to some of the pitfalls in the techniques commonly used on computers. In particular, he considered the stability of two methods of inverting a matrix, and concluded that the method of rotation is not more stable than the method of elimination, although an argument can be adduced to the effect that it is. After this paper, as after all the formal papers presented, there was a lively discussion, in which many of the delegates took part.

A wide-ranging review of the state of the computing art was given by two speakers: Mr. J. A. Goldsmith of Robson, Morrow and Co., and Dr. A. S. Douglas of the University of Leeds. Mr. Goldsmith noted that delivery of 76 installations of electronic computers had so far been made in the United Kingdom and that 33 were on order, although recently the tempo of orders had slackened. Much of the work in the commercial field had so far been unambitious and the results somewhat disappointing. He felt that it would be 5–10 years before computers played a full part in helping management to control their organizations. Dr. Douglas reviewed the work of computers in British universities. Much work has been done in training in their use at the postgraduate-level, and he felt that this could well be extended to the undergraduate-level. He discussed the problem confronting universities in the installation and use of large-scale machinery, and suggested that it would be desirable for three or more of the large fast computers such as *Muse* to be installed in universities, where they would act (on a service basis) as focuses for local computer users. He gave details of serviceability and use of typical present-day university installations, and concluded that a high standard of efficiency can be attained.

All the sessions were very well attended throughout. It is intended in the future to hold annual conferences of the Society at various centres in the United Kingdom, the next conference being planned for June or July 1960. A. S. DOUGLAS

THE INTERNATIONAL INSTITUTE OF REFRIGERATION

THE first International Congress of Refrigeration was held in Paris in October 1908. Shortly after this, in January 1909, the International Association of Refrigeration was established, following the suggestion of Kamerlingh Onnes, the name being changed to the International Institute of Refrigeration just after the First World War. The organization has therefore just celebrated its jubilee.

The general objective of the Institute is the development of the science and techniques of refrigeration in the international field. It promotes scientific research, as well as the teaching and popularization of refrigeration and its application in all fields, particularly in food preservation, health and industrial processes. The International Institute of Refrigeration headquarters are in Paris.

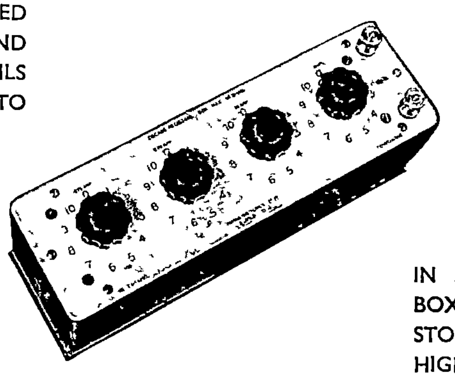
The main tasks of the Institute are determined by the general conference, at present presided over by Dr. Ezer Griffiths. This meets every four years, at the same time as an International Congress of Refrigeration, also organized by the Institute. Executive power is vested in an executive committee. A technical board, of which Dr. J. C. Fidler is the current president, co-ordinates the scientific and technical activity of nine commissions, which between them cover all aspects of refrigeration matters from fundamental research to applications in agriculture, transport, etc.

The tenth International Congress of Refrigeration was held in Copenhagen during August 19–26 and was attended by about 1,500 delegates from all over the world. About 300 scientific and technical

DORAN

DECADE RESISTANCE BOXES

THE INSTRUMENT ILLUSTRATED IS A 4 DIAL DECADE BOX AND MAY BE SUPPLIED WITH COILS HAVING VALUES OF 0·01 TO 10,000 OHMS



IN ADDITION TO RESISTANCE BOXES WE ALSO SUPPLY WHEATSTONE BRIDGES—PORTABLE AND HIGH PRECISION TYPES—AS WELL AS STANDARDS OF RESISTANCE

THE WINDINGS ARE BIFILAR AND HAVE LOW RESIDUAL INDUCTANCES BUT FOR AUDIO FREQUENCY WORK ALTERNATIVE WINDINGS CAN BE PROVIDED

RUSSIAN PATENTS

DERWENT INFORMATION SERVICE has now commenced the publication of a fortnightly journal called Russian Patents Report.

This is similar to the existing Derwent Belgian Patents Report and gives very detailed abstracts of all Russian patents in the fields of Chemistry and Chemical Engineering, Metallurgy, Plastics, Textiles, Pharmaceuticals, Photography, Petroleum and all related branches of technology

The abstracts are based upon the full patent specifications and there is not more than about six weeks delay in publication

The subscription rate to the Russian Patents Report is £13 (or $38 sea mail, $45 air mail to United States) for six months For subscribers to any of our other publications there is a concession—the reduced subscription rate being £10 (or $28 sea mail, $35 air mail to United States)

TRANSLATIONS of the full patent specifications are provided at 25/- each ($4 inclusive of air mail to United States) Photo-copies of Russian patents are supplied at 3/6 each or 50 cents air mail to United States.

A specimen copy of the current issue of Russian Patents Report, together with a copy of our pamphlet entitled Russian Patent Law, Procedure and Statistics, will be sent upon application to:

APPLICATIONS OF THE
THEORY OF MATRICES
by
F. R. GANTMACHER

Translated from the Russian by J. L. BRENNER, Stanford Research Institute, California

In this translation of the advanced material in an important Russian work, the original text has been followed very closely except where revision, rearrangement or addition were needed to make the material more lucid and practical to the mature, English-speaking mathematician Entirely self-contained the book and its Appendices provide all the material required for a thorough understanding of the subject. The Bibliography has been re-worked to include Western books in print

s-TRIAZINES
AND
DERIVATIVES
(THE CHEMISTRY OF HETEROCYCLIC COMPOUNDS VOLUME XIII)
by
E. M. SMOLIN and **L. RAPOPORT**
Central Research Division, American Cyanamid Company, Stamford, Connecticut

In their Preface to this book the authors say

" *s*-Triazine, the fundamental member of the series of compounds treated in this volume, was unknown at the time of completion of the manuscript, and has been characterized only recently. Its discussion has been included as part of the Introduction rather than as an Appendix because the authors feel that it ought to be discussed in the most easily accessible location possible. . We have made an effort to consider the *s*-triazines from the point of view of an organic chemist who, entering the field to do research, wants information about the literature An attempt has been made to give physical properties, especially melting or boiling point and solubility, but without taking the space to do more than mention other readily accessible seldom used data Modern electronic concepts of organic chemistry have been called upon where possible although mechanistic and kinetic data are largely lacking in this field "

668 *pages* *illustrated* 226/-

(A full list of all the titles which have been published in this series together with many still in preparation is available from the publishers Subscribers to the complete series can obtain all the volumes at a reduced price)

MACMILLAN BOOKS

Nuclear Reactor Physics

A Practical Text and Guide for Design Analysis of Nuclear Reactors

RAYMOND L MURRAY

A logical and straightforward introduction to the methods of analysis of reactor design with many numerical examples drawn from practical situations in the reactor field The main emphasis throughout the text is on the distribution in energy and space of neutron flux, the determination of the critical amount of fissionable material, and the transient behaviour and control of the reactor as a source of heat *Diagrams 30s*

Transistor Electronics

A W LO, R O ENDRES,
J ZAWELS, F D. WALDHAUER,
CHUNG-CHIH CHENG

This combined work of five authorities in the field of electronics provides students with a thorough study of both the theory and practice of transistors and transistor circuits *Numerous diagrams 45s*

Principles of Automatic Controls

FLOYD E NIXON

Written for the practising engineer, whether aeronautical, electrical, or mechanical, this comprehensive book on the field of automatic controls covers all the most recent methods used in control system design It is the first book in the control analysis field which includes transient analysis, utilizations of automatic computers and numerical integration, as well as frequency response analysis methods *With diagrams 30s*

Theoretical Aerodynamics

Third Edition *L M MILNE-THOMSON,* CBE

The third edition contains a fifty-page chapter on sweptback and delta wings, in which the various cases of the linearised problem of the supersonic delta wing are elucidated in detail by a consistent simple method *40s*

St. Martin's Street, London, W.C.2

Absorption spectrophotometry

By G. F. LOTHIAN, M.A., F.INST P.

This book has been entirely revised and reset for its second edition. It is concerned with the theory, instrumentation, and application of spectrophotometry, which is now one of the principal methods of industrial analysis and process control. Indeed, there are few industries that do not employ spectrophotometers in some form or another in their laboratories. Mr Lothian, now a lecturer in physics at Exeter University, helped at one stage of his career to design several well-known instruments. Price 52s. net

FORESTRY BOOKS

THE NATIVE PINEWOODS OF SCOTLAND
H M Steven
A Carlisle

The native pinewoods of Scotland are important from the aspects of history, ecology and forestry They form one of the most important living monuments of Scotland, they present a unique survival of native vegetation with their own distinctive flora and fauna; and they are of great importance in current forestry practice as a reservoir of distinctive strains of Scots pine The history of the native pinewoods is traced and the ecology of the native pinewoods and the surviving forests is described in detail.

366 pp 20 half-tone plates, 33 line drawings.
63s.

GENETICS IN SILVICULTURE
C Syrach Larsen

The author has stressed the practical side of the subject Every aspect of tree-dealing is dealt with in a lucid and unassuming manner

232 pp. 70 illustrations in line and half-tone
30s

SILVICULTURE
Joseph Kostler

An authoritative textbook on silviculture

422 pp 20 half-tone plates 45s

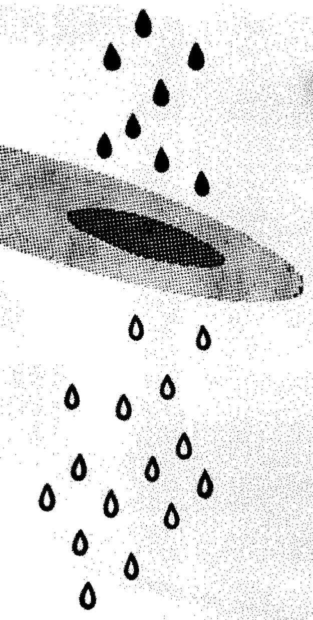
Glass fibre filter papers

open the way to faster filtration

in the sub-micron range



Properties and performance make these papers an outstanding addition to the Whatman range. They open up interesting new uses for filter papers, not least by the economies they show and advantages they possess over sintered glass and other fine porosity filter crucibles. High retentions and rapid filtration rates are an advantage when filtering *very fine* precipitates and semi-colloidal substances. Freedom from blocking ensures speed when separating gels from solutions, as in the filtration of viscose or resin syrups.

Whatman Glass Fibre Papers are used routinely with Buchner and Hirsch funnels and with coarse porosity filter crucibles. They are highly absorbent, resistant to dilute acids and alkalis and may be dried or sterilised at temperatures up to 500°C.

Please write for further information. Trial packs are available from your usual Whatman supplier.

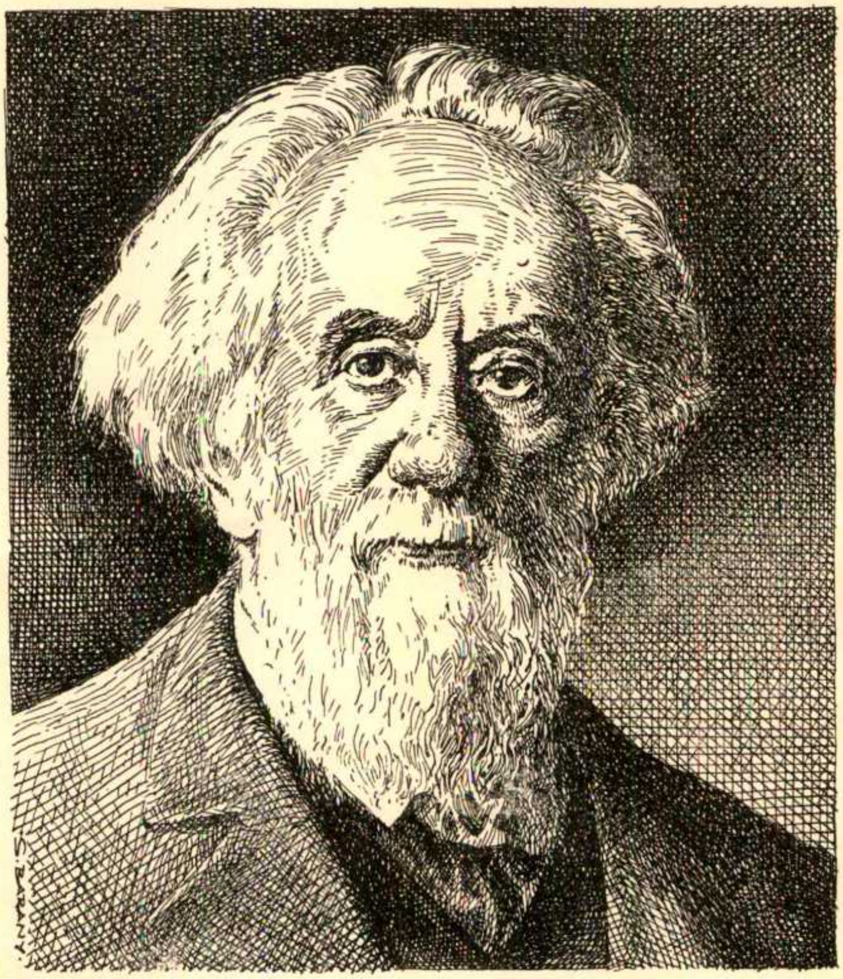
Huggins is a little dissatisfied



'I soon became a little dissatisfied with the routine character of ordinary astronomical work and in a vague way sought about in my mind for the possibility of research upon the heavens in a new direction, or by new methods.' And the direction William Huggins chose led him to chemical analysis of the stars with the spectroscope, and eventually to securing in 1875 the first successful stellar spectrogram—with optics made by Adam Hilger. So another step was taken towards automatic spectrochemical analysis with Hilger polychromators—the quickest, surest, most economical, and most comprehensive method of analysis in science and industry.

papers were discussed at plenary sessions and at meetings of all the commissions held during the period of the Conference

The Institute publishes six times a year a Bulletin which appears in both English and French, the two official languages of the Institute The Bulletin contains abstracts of scientific and technical articles and information about current research in refrigeration and on other refrigeration activities from all over the world The Institute also publishes the works of its various commissions

Full membership of the Institute is restricted to the governments of member countries, which at present number 35, including the United Kingdom, the United States and the U S S R The United Kingdom interests in the Institute are co-ordinated by the Department of Scientific and Industrial Research, with the advice of a Standing Committee representing research, institutional and industrial interests in Great Britain

In 1952, the Institute introduced associate membership, available to qualified firms, institutions or individuals active in the science or in the industry of refrigeration The annual subscription is about £13 for firms and institutions and £3 10*s* for individuals Associate members receive the *Bulletin* and the proceedings of the nine international commissions of the Institute, together with the texts of reports presented Associate members may participate in the work and the meetings of the commissions in which they are interested, and can also use the services of the large library of the Institute Applications for associate membership may be made to the Director of the International Institute of Refrigeration, 177 boulevard Malesherbes, Paris (17°)

STERIC ASPECTS OF THE CHEMISTRY AND BIOCHEMISTRY OF NATURAL PRODUCTS

THE interest taken in stereochemical problems by chemists and biochemists alike has been greatly increased in recent years, and the Biochemical Society recognized this fact by arranging a symposium on "Steric Aspects of the Chemistry and Biochemistry of Natural Products", which was held in the Senate House of the University of London on June 30 The chairman of the morning session, Prof A Neuberger (London), discussed some of the main trends of recent work in this field and emphasized the importance of stereochemistry in modern enzymology

Dr W Klyne (London) then discussed in a comprehensive manner the types of evidence used for establishing relative or absolute configurations of asymmetric compounds The term 'absolute configuration' can now be used with confidence, as Bijvoet and his colleagues working in Utrecht have demonstrated by means of a special X-ray technique that the Fischer convention for glyceraldehyde happens to be correct Dr Klyne pointed out that the most satisfactory method of correlating two asymmetric compounds is by a chemical reaction which does not involve the asymmetric centre The second type of approach is concerned with chemical reactions in which one or more of the linkages of the asymmetric atoms are broken The stereochemical correlation in this situation must be based on kinetic and other evidence and must involve certain assumptions about the mechanisms of the substitution concerned

Dr Klyne then went on to discuss the deductions which can be made from studies of asymmetric synthesis, methods used successfully by Prelog and by Cram Another type of approach which was developed mainly by Fredga in Sweden, and which is probably not sufficiently widely known, is based on the study of melting points of mixtures of a compound of known configuration and a structurally similar compound of unknown configuration If the two compounds have opposite configurations they may form in the solid phase a quasi-racemic compound, and this can be deduced from the melting-point curve

Reference was also made to the information obtained from the applications of X-ray analysis, especially to compounds with more than one asymmetric centre Finally methods were discussed which depend on a numerical comparison of the values of optical rotations of structurally related compounds These calculations and deductions have in the past been largely based on measurements at a single wave-length and have indeed yielded much valuable information In recent years this tool has been made more powerful by extending the measurements to the whole visible and a large part of the ultra-violet range of the spectrum In this development (rotatory dispersion), Djerassi of Detroit has taken the leading part

Steric aspects of the biosynthesis of terpenes and steroids were considered by Dr D Arigoni (Zurich), who discussed first the formation of an isopentane derivative from acetate The early stages of the synthesis consist of a condensation of acetoacetyl-CoA with acetyl-CoA to give the CoA derivative of β-hydroxy-β-methylglutaric acid The latter is then reduced, probably through the aldehydo acid, to β,δ-dihydroxy-β-methylvaleric acid or mevalonic acid The absolute configuration of this compound has been unambiguously related recently by Eberle and Arigoni to that of quinic acid, which in turn had been established by Dangschat and Fischer in 1950 by relating it to glyceraldehyde Dr Arigoni then referred to the stereochemical problems involved in the conversion of leucine to β-hydroxy-β-methylglutaconic acid, which occurs through the CoA esters of β-methylcrotonic acid and β-methylglutaconic acid The hydration of the double bond and the carboxylation of methylcrotonic acid must be stereospecific and this is also likely to apply to the reduction of mevaldic acid to mevalonic acid The next steps in the reaction sequence are the simultaneous decarboxylation and elimination of the tertiary hydroxyl group from the pyrophosphate of mevalonic acid to give isopentenyl pyrophosphate and the isomerization of the latter to give dimethylallyl pyrophosphate , it can be postulated that the isomerization is stereospecific and Dr Arigoni thought it probable that only one of the two hydrogen atoms of isopentenyl pyrophosphate is involved in the isomerization

The allyl compound is assumed to react with the isopentenyl pyrophosphate, resulting in the formation of a new C—C bond This reaction must again have stereospecificity, since the new double bond produced usually has a *trans* configuration , but Dr Arigoni stressed the fact that the detailed mechanism of the formation of this condensation is not yet securely established and he suggested that experiments involving labelling with deuterium and determining the axial or equatorial position of the deuterium in a suitable cyclization product are likely to give further information.

Dr Arigoni pointed out that steric factors had to be taken into account in any attempts which were made to explain the actual cyclization and the rearrangements which either follow the cyclization proper or are coupled with it Otherwise, it would be difficult to explain the formation of diastereoisomers from one single aliphatic precursor, squalene If a carbonium ion is involved in cyclization reactions, it can only have a structure which preserves the original configuration , a 'bridged ion' fulfils this requirement and addition of this relatively stable species to a base or nucleophilic substance ('antiplanar addition') will produce only one isomer The postulate of antiplanar addition imposes restrictions on the type of folding and it appears that only the chair-type and boat-type of folding explain, for example, the formation of both lanosterol and tirucallol from *all-trans* squalene Experimental evidence for the theory is provided by the work of Bloch and by that of Cornforth and Popják Further interesting examples from the work of Dr Arigoni himself and from that of Prof Birch were given, showing the application of stereochemical rules to the biogenesis of terpenes, but a note of caution was sounded against the assumption that the configuration of the *A*/*B* ring junction is always the same

Steric aspects of drug action were discussed by Dr R B Barlow (Edinburgh), who began his talk by emphasizing the distinction first made by Stephenson between affinity or adsorbability of a drug to a receptor site, and efficacy, that is, the ability of the adsorbed drug to start a sequence of reactions which can be observed in a pharmacological experiment While it is possible to make definite statements about the steric arrangement of drugs, ideas on the stereochemistry of receptors are generally based on somewhat uncertain deductions made from structures of active compounds and those of their antagonists

Dr Barlow illustrated his talk with examples from the field of drugs resembling acetylcholine either in its muscarine-like or nicotine-like function or of compounds antagonizing such action For nicotine-like activity the molecule should contain a cationic head such as a dimethylamino or trimethylamino group and a partial positive charge at a distance similar to that which separates the ether oxygen of acetylcholine from the charged nitrogen atom In nicotine itself the two optical isomers have identical pharmacological activities The constitution and stereochemistry of muscarine have recently been worked out and it is found that it has three centres of asymmetry Dr Barlow then discussed the activities of the various stereo-isomers of muscarine and of various synthetic substrates resembling this substance pharmacologically, such as acetyl-β-methylcholine In this case the (+)-isomer is reported to be about 200 times as active as the (−)-isomer Dr Barlow then mentioned the importance of steric factors in flexible molecules and he pointed out that in these cases it is more difficult to arrive at quantitative conclusions In particular, the work of Schueler was discussed in detail and some recent criticisms of his calculations were mentioned Dr Barlow then dealt in some detail with di-quaternary bases, such as various esters of aliphatic dicarboxylic esters containing two quaternary basic groups, such as suxamethonium The many examples which were considered illustrated the difficulties which still exist if one attempts to correlate the stereochemistry of the compounds under consideration with their biological activity

The last paper of the morning session was given by Dr G A J Pitt (Liverpool) on behalf of Prof R A Morton and himself, and dealt with *cis-trans* isomers of retinene in visual processes Dr Pitt briefly discussed the chemistry of retinene (vitamin A aldehyde) and that of vitamin A, and in particular referred to the early work of Pauling which predicted the existence of the following four isomers all-*trans* , 9-mono*cis* , 13-mono*cis* , and 9 13-di*cis* These four isomers of retinene and vitamin A have been synthesized, but it has been possible to prepare two other retinenes and vitamins A containing a *cis*-linkage in the 'hindered' 11-position No 7-*cis* vitamin A has yet been prepared and it seems almost certain that 7-*cis* isomers cannot exist, as in such a molecule there would be considerable steric interference Dr Pitt then referred briefly to the occurrence of *cis*-isomers in Nature, and mentioned that the thermodynamically most stable isomer and the one found most commonly in Nature is the all-*trans* isomer He then reviewed the isomerization of the various retinene isomers and their absorption spectra The importance of the *cis-trans* isomerization was appreciated when Hubbard and Wald found that the retinene which united with opsin was the 11-*cis* form The 9-*cis* form also reacted with opsin but the resulting complex has not been found in Nature The main effect of the introduction of a *cis*-bond at the 11-position is that it produces a bend of the side-chain whereas in the all-*trans* isomer the side-chain is straight When rhodopsin is illuminated it breaks down to the protein opsin and a retinene, but the latter was found, rather surprisingly, to be the all-*trans* isomer This all-*trans* retinene liberated by the bleaching of rhodopsin does not give rhodopsin again when mixed with the opsin *in vitro*, and strong evidence has been obtained by Hubbard that the utilization of the *trans*-isomer in a more complex system is caused by the presence of an enzyme called retinene isomerase, which changes the all-*trans* retinene to the 11-*cis* isomer Dr Pitt discussed this enzymic isomerization in more detail and then went on to report on recent work which has been done on invertebrate rhodopsins, dealing in particular with indicator yellow He also gave an account of the effect of light on various rhodopsins under a variety of conditions, but it would be impossible to summarize adequately the rather complicated relationships which have been established, mainly due to the work of Hubbard and Wald

The chair was taken for the afternoon session by Prof S Peat (Bangor) , all three papers were devoted to various aspects of stereospecificity in enzyme action Dr E C Webb (Cambridge), who dealt with hydrolytic enzymes, treated some general matters relevant to all enzymes He emphasized that enzymic catalysis is at least a two-stage process, and that steric factors may be important both in the formation and in the breakdown of the intermediate enzyme-substrate complex To be of real value any comparison of substrates should involve measurement of both the Michaelis constant (K_m) and the reaction velocity, as measures of the two stages

Examples considered included *ali*-esterases and lipases, cholinesterases, glycosidases, lactonases, peptidases, arginase and fumarase For the cholinesterases knowledge has accumulated which permits the representation of the catalysis in terms of anionic and esteratic sites on the enzyme surface The high specificity of glycosidases is well known, and this is paralleled in the recently studied group of lactonases Proteolytic enzymes may be used, thanks to their high stereospecificity, as tools for the resolution of synthetic amino-acids Work on the behaviour of synthetic substrates as competitive inhibitors of α-chymotrypsin emphasizes the importance of distinguishing the two stages of enzyme action

In conclusion, the importance of Ogston's concept (1948) of three-point attachment between enzyme and substrate was emphasized This idea explains very simply the formation from a symmetrical substrate (CX_2YZ) of an asymmetric product (CXX^1YZ) Ogston has recently discussed this concept further (1958)

Dr H Gutfreund (Shinfield) in discussion considered further the specificity of α-chymotrypsin, in the reactions of which three stages can be distinguished ($E + AB \rightleftharpoons E\text{-}AB \rightleftharpoons EA + B \rightleftharpoons E + A + B$)

Prof E C Slater (Amsterdam) dealt with oxidation-reduction enzymes He began by considering dehydrogenases which act on hydroxy acids and more complex systems which can (indirectly) transform one enantiomer into the other (commonly but wrongly called racemases) After a brief discussion of amino-acid oxidases the greater part of the paper was devoted to stereospecificity of hydrogen transfer in the reactions of pyridine nucleotide dehydrogenases These compounds are dinucleotides, one unit of which is the nicotinamide group which can undergo reversible oxidation and reduction at N and C–4 The elegant work of Vennesland's school in Chicago using substrates and enzymes labelled with deuterium has shown that these dehydrogenases fall into two classes , these are distinguished by the fact that they add hydrogen at C–4 of the diphosphopyridine nucleotide molecule on opposite sides Other related work dealt with reactions involving cytochrome *c*, flavin and orotic acid

An important extension of Vennesland's work was the preparation of stereospecifically labelled and optically active CH_3 CHDOH Alternative mechanisms of action for a typical dehydrogenase have been suggested by Dixon and Webb in their classic textbook on "Enzymes", and by Van Eyk, Kaplan *et al*

Finally, succinic dehydrogenase, which involves another type of stereospecificity, was introduced

Dr H R Levy (Chicago) emphasized in discussion that the stereospecificity in the reactions of pyridine nucleotides is another example of the ability of enzymes to distinguish between two identical groups, and gave further examples Dr W Klyne directed attention to the important work of Prelog on microbiological oxidations and reductions of simple decalones and related compounds The pictorial treatment of these reactions may constitute a valuable extension of Ogston's concept of three-point attachment

Dr G R Barker (Manchester) dealt with enzymes of nucleotide metabolism He began by outlining current views on the biosynthesis of D-ribose and 2-deoxy-D-ribose , the important routes leading to ribose involve the 5-phosphates of D-xylulose and D-ribulose The formation and fission of glycosidic bonds in nucleosides was next considered , these reactions are generally phosphorolyses and not hydrolyses The stereochemistry of analogous chemical syntheses of nucleosides has been studied with respect to relative configurations at C–1 and C–2, and it is necessary to consider how far the stereospecificity of the enzymic reaction is attributable to the enzyme, and how far it is inherent in the nature of the reaction catalysed The answer at present is that both factors are involved

The formation and fission of internucleotide links in polynucleotides were then discussed Pancreatic ribonuclease degrades ribopolynucleotides via nucleoside 2′,3′-(cyclic)-phosphates to 3′-phosphates, and the steric factors involved in this and the reverse reaction were considered Finally, the polynucleotide phosphorylases were considered , many reactions require a polynucleotide 'primer', the composition of which determines that of the polymer formed , this is a direct demonstration that the primer acts as a template

All three papers emphasized in different ways the essentially complementary nature of enzyme and substrate and the two (or more) stage character of the enzyme-substrate reaction

A NEUBERGER
W KLYNE

OIL IN NAVIGABLE WATERS

IT is now seven years since a group of representatives of the interests in Great Britain which are most affected by oil pollution formed themselves into the Co-ordinating Advisory Committee on Oil Pollution of the Sea, under the chairmanship of Mr James Callaghan, M P In 1953 this Committee organized an international conference in London which called for a meeting of governments of all maritime countries to take action to prevent the growing pollution of the oceans of the world This request met with considerable success, for an inter-governmental conference was held in 1954, at which an international convention was drawn up This Convention came into force in July 1958, and has been ratified by the United Kingdom, Belgium, Canada, Denmark, Finland, France, the Federal Republic of Germany, the Irish Republic, Mexico, the Netherlands, Norway and Sweden

The Convention does not prohibit the discharge of waste oil entirely, but merely within certain zones, and the countries which observe the Convention represent only about one-half of the world's tanker shipping, notable omissions being the United States, U S S R , Poland, Italy, Panama and Liberia The Co-ordinating Advisory Committee on Oil Pollution of the Sea therefore decided to organize an international conference to discuss, among other aspects, how far the 1954 Convention had been effective in diminishing the contamination of coasts and beaches, and the destruction of bird life This Conference was held in Copenhagen during July 3–4 It was presided over by Mr James Callaghan, M P, with Dr Bøje Benzon (chairman, Danish National Section, International Council for Bird Preservation) and Hr Ekspeditionssekretær Sven Lunddahl (Secretary, Danish Council for the Prevention of Oil Pollution of the Sea) as vice-chairmen

The meeting was very well attended, and included a wide range of interests, for among those present were representatives of government departments of transport and commerce, ship owners, port authorities, ship repairers, seamen's unions, sea-fisheries associations, local authorities, pleasure resorts, tourist organizations, hotel and restaurant associations, and conservation, ornithological, and humanitarian organizations, of many countries, together with the diplomatic representatives of nineteen nations In addition, seven international bodies, the Intergovernmental Maritime Consultative Organization, the Food and Agriculture Organization, the Council of Europe, the International Union of Biological Sciences, the International Council for Bird Preservation, the International Union for the Conservation of Nature and Natural Resources and the World Federation for the Protection of Animals were represented

The Conference was opened by Mr Helge Juul, deputizing for the Danish Minister of Commerce, and the first section of the proceedings was devoted to a review of the situation arising from the 1954 intergovernmental Conference In a paper on the working of the Oil in Navigable Waters Act, 1955, Mr D C Haselgrove, under-secretary, U K Ministry of Transport and Civil Aviation, pointed out that the provisions of this act go beyond the basic requirements of the 1954 Convention, and quoted as an example that the sea zones in which British ships registered in the United Kingdom must not discharge oil extend beyond the zones laid down in the Convention He paid a warm tribute to the ready co-operation of British ship owners, dock and harbour authorities, and the oil industry Capt K C Angus, Marine Regulations Branch, Department of Transport, Canada, in a report on the preventive measures taken by the Canadian Government, stated that the coasts of Newfoundland suffered most from oil pollution, and after them the eastern maritime provinces and the St Lawrence river, but the whole Atlantic coast was subject to heavy and habitual contamination He stressed the value of weight of public opinion, and directed attention to the fact that in many countries only a very small percentage of the population was aware of the existence of oil pollution and its serious consequences Mr Lester A Giles, jun, American Humane Education Society, in association with Mr John W Mann, State Department, Washington, D C, announced that an inter-departmental Committee had unanimously adopted a draft report for submission to the Secretary of State, recommending that the United States accept the 1954 Convention with reservations of a technical nature, a statement that was received with acclamation

In a paper dealing with the working of the Convention from the point of view of British tanker and oil companies, it was recalled that since the Second World War the use of oil, and consequently the number of tankers, had increased enormously, and that ownership was now spread over a great variety of flags, some quite new to shipping, and it was urged that universal ratification be strenuously pursued In the discussion regarding methods of cleaning cargo tanks which followed, Mr A Logan (Shell Tankers, Ltd) uttered a word of warning regarding the indiscriminate use of chemicals, and pointed out that the use of large amounts of detergent might lead to a situation even more destructive and less manageable than that arising from the original oil-sludge

Disposal of oil waste and facilities in ports were dealt with by speakers from Denmark, the Netherlands and the United Kingdom Mr S Glazenburg (Netherlands) forecast that the consumption of 134 million tons of oil by European countries in 1957 would rise to a consumption of 190 million tons in 1963 and 340 million tons in 1975, with a corresponding expected rise in refinery capacity, particularly in Western Europe Comparatively more oil products would be exported from Western Europe, and in proportion to this increase in oil movements the problem of the disposal of oil residues would become more acute

Speaking for 43 coastal municipalities in the Netherlands the Burgomaster of Bergen described the system of weekly reports on the condition of the beaches in Holland, which are summarized annually in order to give a general survey of the amount of oil pollution during the year He urged that municipalities in other countries should organize similar surveys and that the information should be co-ordinated on an international scale. From the point of view of tourism it was pointed out by Mr Eric D Croft, director-secretary of the British Hotels and Restaurants' Association, that dollar earnings from tourism exceed the total value of exports of cars and Scotch whisky together from the United Kingdom to the United States, and he stressed the serious loss to the tourist trade presented by pollution of beaches

Reports, on the destruction of birds by waste oil, received from Canada, the German Federal Republic, the Netherlands, Newfoundland, Poland and the United Kingdom, showed that in the Netherlands it was estimated that a minimum of 20,000 and a maximum of perhaps 50,000 birds are destroyed annually, and that 50 different species have been affected, in Newfoundland all species of sea-birds around the coasts are victims, further evidencing the great toll of sea birds which has been continuing for more than forty years

Major Bertil Funck (Sweden) directed attention to the recurring pollution of the Baltic, especially east and south-east of the island of Gotland Under the Convention there is an area in the Baltic, south-east of Gotland, 50 nautical miles from the island and the mainland, where discharge of oil is permitted He epmhasized that the Baltic is too small in area for oil discharge, and proposed that a resolution be passed seeking to obtain the inclusion of the Baltic as a prohibited zone for oil discharge He also recommended that the whole North Sea should similarly be declared a prohibited zone

The representative of the secretary-general of the Inter-governmental Maritime Consultative Organization, Kommerseraadet G M E Boos, stated that the bureau functions for the International Convention for the Prevention of Pollution of the Sea by Oil had been discharged by the United Kingdom up to June 15, 1959, when the Organization took over the duties and obligations conferred upon it under the terms of the Convention Among other responsibilities the Organization would have the duty of convening a further conference to review both the working of the Convention, and the possibility of bringing about complete cessation of discharge of persistent oils into the sea In resolving to take over its functions, however, the Organization pointed out to the governments concerned that, owing to other urgent tasks, it would not be possible to convene a further conference before 1961 Mr Boos ended on a personal note, stating that though the convening of a further conference on oil pollution was not an obligation made under the Convention, he would characterize it as a moral undertaking inspired by the first resolution of the 1954 Conference The aim of that resolution was certainly the same as the object of the present conference, namely, the complete avoidance of discharge of persistent oils into the sea, which, so far as was known, was the only entirely effective method of preventing oil pollution

Two resolutions were adopted by the conference The first urged that the governments of countries which had not yet ratified the Convention of 1954 should do so , that further efforts should be made to impress upon governments and upon ship owners and ship's officers and crews the serious consequences arising from the discharge of oily wastes into the sea , that all necessary facilities be provided for the disposal of oily wastes in main ports and harbours , that technical research into means of avoiding discharges of oily wastes into the sea be intensified, and the results made widely known through the Inter-governmental Maritime Consultative Organization , that with a view to achieving the aim of total avoidance of the discharge of persistent oils into the sea, the governments and the Organization should make preparations for holding a further inter-governmental conference as soon as possible

The second resolution, though reiterating the only effective solution of the problem, proposed in the meantime an extension of the prohibited zones for oil discharges in such areas as the Gulf of St Lawrence, the Grand Banks of Newfoundland, and the eastern seaboard of North America, and also in the Baltic and North Seas P BARCLAY-SMITH

RADIOACTIVATION ANALYSIS

NEW methods of chemical analysis using techniques derived from nuclear physics were discussed at a Symposium on Radioactivation Analysis held in Vienna during June 1–3 Sponsored by the International Atomic Energy Agency and the International Council of Scientific Unions, the meeting brought together research workers from twenty-one countries for the first international conference on a subject of rapidly growing importance in many branches of science, medicine and industry

An introductory survey by G B Cook (Atomic Energy Research Establishment, Harwell) was followed by reviews of the uses of activation analysis in geochemistry (W. Herr, Max-Planck Institute of Chemistry, Mainz), biochemistry and medicine (J M A Lenihan, Western Regional Hospital Board, Glasgow) and metallurgy (J Hoste, University of Ghent) P Leveque (Centre d'Études Nucléaires, Saclay) spoke of applications in industry and G W Leddicotte (Oak Ridge National Laboratory) described recent developments in the United States Several shorter contributions were also given

Most analytical methods depend on the behaviour of electrons Activation analysis depends on the properties of the nucleus, in particular the radioactivity induced by bombardment with neutrons or other particles Many elements have isotopes which decay slowly enough for the assay to be done a day or two after irradiation, but work on short-lived activities can only be done close to a neutron source A reactor is the instrument of choice for activation analysis, but more modest facilities are often serviceable Discharge tubes using the deuterium–tritium reaction give neutron fluxes as high as 10^9 n/cm ^{2}/sec at moderate cost Useful work has been done with the lower fluxes provided by radium–beryllium or antimony–beryllium sources , a recent innovation is the americium–beryllium source, which has the merit of freedom from residual γ-ray emission

Since nearly seventy elements become appreciably radioactive after a few hours exposure inside a nuclear reactor of moderate thermal neutron flux (10^{12} n/cm ^{2}/sec), the irradiated sample generally contains several different activities Fortunately many of the common matrix elements (aluminium, silicon, iron, carbon, nitrogen, oxygen) have relatively small cross-sections for thermal neutron capture Differences in half-life and decay energy between trace element and matrix or between different trace elements in the sample are also advantageous

The isolation of individual activities for radioactive assay may often be achieved by γ-ray spectroscopy, but a preliminary chemical separation is generally advisable, even when dealing with short-lived nuclides When once the experimental material has been irradiated, along with a known amount of the element under investigation (to serve as a standard), the isolation may be simplified by the addition of stable carrier in any desired amount Another useful advantage of the activation method is that contamination of reagents, often a source of trouble in the micro-determination of trace elements, need not be considered at all

The sensitivity of thermal neutron activation analysis for trace estimation is remarkable Many elements can be estimated at levels of 10^{-8} to 10^{-11} gm using a neutron flux of 10^{12} n/cm ^{2}/sec acting on a 1-gm sample The detection of trace elements by this method has been useful in several industrial problems, notably the measurement of deliberate or fortuitous contamination in semi-conductor materials Applications in the oil industry are so numerous (and so important financially) that many companies have acquired neutron sources of their own A typical problem, in which conventional methods of analysis are not sufficiently sensitive, is the control of vanadium, which acts as a catalyst poison in cracking operations and as a corrosive agent in fuel oils

The same element is important in a different connexion as a constituent of high-alloy steels Here the activation method of analysis is valuable for its speed and accuracy A 10-second irradiation, at a flux of 10^{10} n/cm ^{2}/sec , is sufficient for analytical determinations using the isotope vanadium-52 (half-life 3 8 minutes) In prospecting for vanadium, a useful technique is to lower into a borehole a neutron generator. After a few minutes the generator is replaced by a scintillation counter to estimate the vanadium-52 activity.

In geochemistry, where the study of natural radioactivity has been of prime importance for more than half a century, the new possibilities offered by activation analysis have been welcomed. A powerful technique for age determination in rocks and meteorites depends on measurement of the relative abundance of parent and daughter nuclides in a natural radioactive decay process. Useful improvement in sensitivity can be expected where one or both of the nuclides can be subjected to activation analysis. Potassium/argon and rubidium/strontium ratios are readily measured in this way. Uranium-238 can be estimated down to a limit of 10^{-12} gm. by the reaction ^{238}U(n, $\gamma\beta$)^{239}Np. For uranium-235 the limit of sensitivity so far achieved (at the Argonne National Laboratory) is 5×10^{-11} gm., using the reaction ^{235}U(n, f)^{140}Ba.

Activation analysis of biological material has attracted relatively little attention, though the method has many interesting potentialities. Several elements, including vanadium, manganese and cobalt, are important to plants or animals but their function in human nutrition is still obscure, through lack of sufficiently sensitive analytical methods. The role of vanadium in dental caries and of manganese in bone formation were two of the subjects suggested for study by activation analysis. Many problems in dental science and in animal biochemistry are also awaiting exploration by activation methods.

Arsenic is an element of continuing interest in clinical science, partly because of its increasing uses and hazards in agriculture and partly because it is the only component of tobacco smoke known to be carcinogenic in man. Arsenic-levels in normal tissue are too low for accurate estimation in living subjects by conventional methods. Activation analysis has been used in several investigations of arsenic poisoning, whether accidental or homicidal. An unusual toxicological experiment was the recent study by activation analysis of the remains of Erik XIV, a sixteenth-century Swedish king who died in mysterious circumstances. These tests gave support to the theory that he was poisoned by mercury, said to have been administered in a dish of pea soup.

Although thermal neutrons are the most versatile agents for activation analysis, fast neutrons have some distinctive applications. The estimation of traces of oxygen has been done satisfactorily by mixing the experimental sample with lithium fluoride and irradiating with fast neutrons to produce the reaction ^{6}Li(n α)^{3}H followed by ^{16}O(^{3}H, n)^{18}F (half-life 112 min.). The limit of sensitivity of this method, as practised at Harwell, is 5×10^{-7} gm. of oxygen. Protons have been used for the estimation of boron in silicon, a test of considerable importance to transistor manufacturers. Neutron activation yields no suitable isotopes but fast protons induce the reaction ^{11}B(p, n)^{11}C (half-life 20.4 min.). The silicon provides an internal standard by the reaction ^{30}Si(p, n)^{30}P. Concentrations of boron as low as 1 in 10^{9} have been measured in this way. Proton activation is useful also for the estimation of boron in germanium. Deuterons provide the best method for the estimation of magnesium in iron, by the reaction ^{24}Mg(d, α)^{22}Na. An internal standard is given by the reaction ^{56}Fe(d, α)^{54}Mn.

Two conclusions emerged from the symposium. The first is that any laboratory using conventional methods of chemical or spectrographic analysis would do well to explore the possible advantages of activation methods for some of its work. The second is that activation analysis, though superficially a simple technique, requires considerable skill in nuclear physics and in analytical chemistry for the full realization of its possibilities.

The success of the meeting was enhanced by the genial hospitality of the sponsors and by the agreeable atmosphere of the magnificent new conference suite of the International Atomic Energy Agency in the Hofburg. The proceedings of the symposium will be published shortly in book form. A long-awaited manual of experimental procedures is in an advanced state of preparation at Oak Ridge.

J. M. A. LENIHAN

THE CAPE TOWN SCIENCE EXHIBITION, 1959

ENCOURAGED by the success of the Science Exhibition held in Cape Town in March 1958, the Cape Council of the South African Association for the Advancement of Science, in collaboration with the Royal Society of South Africa, organized the second Science Exhibition in more spacious surroundings (10,500 sq. ft.) during the period April 6–11. After introductory addresses by the chairman of the Organizing Committee and vice-president of the South African Association for the Advancement of Science, Dr. Ronald Singer, and by H.M. Astronomer at the Cape, Prof. R. H. Stoy, the Exhibition was officially opened on the evening of April 6 before a distinguished audience of scientists, industrialists and educationists by His Excellency the Governor-General, Dr. E. G. Jansen.

Dr. Jansen stated that the Exhibition must be of particular interest to the layman, "because although one does not always understand all that science has to teach us, one realizes the importance of science and scientific research especially in the troublous times in which we live, and where science has, to a large extent, changed the life of civilized man and touches our everyday life at every point".

Dr. Jansen indicated that it is a rather startling thought that, according to some reports, the Soviet Union is more advanced than any other country, not only in certain fields of scientific research but also in the number of men and women receiving education and training in science and scientific methods. "The question arises as to whether sufficient is being done in that direction in our country. ... If we believe that the future of the country is in the hands of the youth of to-day, we should surely see to it that the education of our boys and girls is in the hands of men and women most fitted for the task, and who are devoted to their work. It follows that they should be adequately remunerated and enjoy fair conditions of employment."

The organizing committee produced a handsome brochure of 48 pages, providing not only a guide to the twenty-seven exhibits but also a general description of the scientific methods behind each exhibit. In the introduction, Dr. Singer stated that "the Exhibition is an attempt to present to the lay-public interesting aspects of modern scientific research and the application of science to industry and commerce. Some, if not most, of the important research projects and applications of research to industry in South Africa have been carefully assembled for the public of Cape Town and environs. A wider understanding of scientific endeavour and its vast potential will inspire lay individuals and give them some insight into the multitude of problems besetting almost every aspect of our daily lives—which we generally take for granted. Ignorance of these matters must only provide a false sense of security—an 'acceptance without contemplation' which can only end in a degeneration of our standards of civilization".

The exhibits (fixed at twenty-seven because of the limitations of space) were of three types—pure science, applied research and modern technical equipment. The South African Council for Scientific and Industrial Research presented a display depicting the nature and scope of its nine national research laboratories (roughly as outlined in *Nature*, 183, 853; 1959), a demonstration on the electrodialysis process for desalting water, and a poster-demonstration of the theme "The Planet Earth", emphasizing the international character of the recent International Geophysical Year. The methods of geophysical research were dramatically illustrated. The United Kingdom Information Office presented an impressive display outlining Britain's role in the development of power from the atom. Models of Calder Hall and *Zeta* provided the basis of the exhibit.

The Division of Fisheries presented its integrated programme of pelagic fish research, indicating the types of problem investigated and the directions in which the research has progressed. It clearly outlined the essential part it played in the £15 million fishing industry. In addition, the Fishing Industry Research Institute at the University of Cape Town provided an exhibit covering three aspects of its research—electrical thermometers on board ships, protein analysis and the bacteriology of fish.

The South African Broadcasting Corporation provided a unique studio to display the great deal of research and development work that lies behind a modern transmission system. The methods used to minimize distortion and noise were demonstrated. The South African Railways and Harbours' exhibits demonstrated centralized traffic control, the draught arrangement and problems in modern locomotives and the ultrasonic testing of materials.

The tellurometer microwave system of precise measurement of distance (an electronic device which measures distance between a master unit at one end and a remote unit at the other by phase comparison of a number of pattern frequencies) was invented in South Africa and is now used in many parts of the world. This was one of the exhibits by a number of industrial and commercial firms, including modern methods of sock-making, the scientific aspects of a modern motor-car, echo-sounders, industrial closed-circuit television, automatic alarm equipment on sea-going vessels, modern metal-spraying equipment, prevention of corrosion, atomic power in the oil industry, the bacteriology of canned foods, the standardizing of colours of printing inks, etc.

The South African Trigonometrical Survey exhibited the methods and techniques in modern survey operations. The Division of Entomology indicated the more important aspects of two of its research projects on forest and timber insects. Dr. S. H. Skaife exhibited his ingenious and simple equipment used in studying the habits and nature of some of the 400 species of ants in South Africa. The South African Museum's exhibit demonstrated a 14-ft. fibre-glass cast of a slab of rock containing the footprints of three mammal-like reptiles which lived 200 million years ago in Basutoland.

The South African Association for the Advancement of Knowledge and Culture displayed methods of promoting science education.

The most dramatic and most popular exhibit was that of the Department of Surgical Research of the University of Cape Town, which had a working heart–lung machine, and films and slide demonstrations on open-heart surgery. Approximately twenty people a day were treated for syncope by the St. John Ambulance Brigade.

Films of scientific interest were screened throughout the daily 12-hr. period when the Exhibition was open in a specially erected cinema inside the hall.

Approximately 17,000 people of all races visited the Exhibition, in comparison with 5,000 who attended the 1958 Exhibition. As a result of the sale of the brochure and the renting of exhibition space to commercial firms, more than £1,200 was collected. Most of this money will form the basis of a fund to provide scholarships to suitably qualified young men and women who wish to take up science as a career.

This Exhibition is part of an ambitious programme on which the Cape Council of the South African Association for the Advancement of Science has embarked during the past three years to stimulate an interest in and an understanding of the progress of modern science among non-specialists and laymen. The Council organizes four to five science film shows a month which attract capacity audiences, and, in addition, fortnightly luncheon film shows are put on at the South African Museum (where there is at present also a planetarium attracting visitors). Through the Council's initiative, refresher courses for science teachers are now regularly provided at the major South African universities, and at present the first in a series of autumn lectures (based on the Christmas Lectures in the United Kingdom) is being arranged for senior pupils at schools in and around Cape Town. Regular conversaziones are held, and last year the Council organized the Darwin–Wallace centenary week of exhibitions, lectures and symposia on evolution. A special committee is investigating science teaching, and particularly mathematics, in schools and making recommendations for improvement to the educational authorities. The formation of a Parliamentary and Scientific Committee is being mooted, and the Cape Council is already planning for the Diamond Jubilee Congress of the Association in 1962, when it hopes to invite distinguished scientists from overseas.

The Cape Council of the South African Association for the Advancement of Science firmly believes that in providing these services to the lay public it will eventually produce noticeable effects on the future leaders of not only science but also politics, religion, ethics and moral philosophy.

RONALD SINGER

THE PHYSICAL SOCIETY

THE contents of the 1958 Year Book of the Physical Society (pp v+106 London Physical Society, 1958 12*s* 6*d*), the fourth in the annual series, follows the pattern of previous volumes It contains the texts of the ninth Charles Chree Lecture, the thirteenth Holweck Lecture and the forty-second Guthrie Lecture , the addresses delivered by the recipients of the thirty-fifth Duddell Medal and the fourteenth Charles Vernon Boys Prize , the discourses given at the forty-second Physical Society exhibition of scientific instruments and apparatus , obituary notices of six fellows including Viscount Cherwell , and the report of the Council of the Society for 1957

In his Guthrie Lecture, Prof W E Lamb spoke about some experimental tests of quantum electrodynamics and explained how measurements of the fine structure of hydrogen and similar atoms by microwave methods have provided valuable information about the interactions between elementary particles and have stimulated theoretical calculations The Holweck Lecture, which was delivered by Prof A Abragam (Centre d'Études Nucléaires de Saclay) on May 1 at Cambridge, was entitled "Spin Temperature", and in it he showed by various examples how the concept of spin temperatures, positive or negative, is not only valid but also most fruitful The secular variation of the magnetic field of the Earth has been known for many years, but it is only recently that any reasonable theories for the variation have been developed In his Charles Chree Lecture, Sir Edward Bullard surveyed the experimental knowledge on the subject, and indicated that the theory that the variation is due to motions in an electrical conducting fluid core has much to commend it and is closely related to the dynamo theory of the origin of the main field

The measurement of the thickness of the helium film was the subject of the Duddell Medal address given by Prof L C Jackson He described how, in experiments at Bristol, a polarized light method used for the determination of the thickness of thin films of transparent materials was adapted to the measurement of the thickness of the helium film and how by a steady improvement in technique consistent observations were made of the helium-2 film as a function of height and temperature The Charles Vernon Boys Prize address, entitled "Development of Bubble Chambers and some recent Bubble Chamber Results in Elementary Particle Physics", is a verbatim account taken from a tape recording of Dr D A Glaser's talk which he delivered at Harwell on July 10, 1958

The lectures and addresses will interest all physicists, but they deal with specialist subjects The general reader will perhaps be attracted mostly by the discourses, and in particular by Mr M H Wilson's account of Goethe's colour experiments, which is illustrated by some coloured prints The other two discourses deal with some uses of physics in archæology (ultrasonic cleaning , proton magnetometry , optical, X-ray and gamma-ray spectrometry , and magnetic and radioactive dating), and some recent investigations with aircraft on the physics of clouds and rain

The Year Book is now the only publication of the Physical Society which is issued free to members It is a most valuable and well-produced volume, and it is hoped that it will continue to be issued, even when the proposed amalgamation of the Society with the Institute of Physics actually takes place S WEINTROUB

THE NATIONAL PHYSICAL LABORATORY

THE various changes in the work and organization of the National Physical Laboratory at Teddington, which have either taken place or are under active consideration, are outlined in the annual report (Report of the National Physical Laboratory for the year 1958 Pp viii+134+8 plates London H M Stationery Office, 1959 8*s* net), which has recently been published It contains the report of the Executive Committee, which was presented to the General Board at its meeting on May 28, one of the annual open-days of the Laboratory , detailed reports prepared by the respective superintendents, of the work of the nine divisions of the Laboratory , the names of members of the Board and its committees, and of the senior staff of the Laboratory , and lists of the various papers published by the director and members of staff during the year

In accordance with the recommendations of the review committee set up in 1957 to consider the organization and research programme of the Laboratory, the Electricity, Metrology and Physics Divisions were replaced by the three new Divisions of Applied Physics, Basic Physics and Standards Work on the differential analyser in the Mathematics Division , on refractories in the Metallurgy Division , and on glass working in the Light Division, has been discontinued In the Applied Physics Division the future of the high-voltage work has not yet been decided, but the testing of magnetic materials has been allowed to continue New projects in this Division are radiocarbon dating and the development of a national centre for neutron source standardization In the Mathematics Division increased emphasis is to be placed on theoretical physics, and with *Ace* now almost complete and in use by the Mathematics Division, the Control Mechanisms and Electronics Division has been re-orientated to new fields of research such as process control by computers that learn to make correct changes by trial and error methods, and the development of new components for very high-speed computers

No marked changes are contemplated in the research programmes of the Light, Metallurgy or Standards Divisions The principal change in the work of the Ship Division is that more attention will be given to problems connected with the sea-going qualities of ships in rough water Dr E Lee, previously director of operational research to the Admiralty, who was appointed to fill the new post of deputy director of the Laboratory, is expected to be of considerable assistance in connexion with the extension of the impact of the work and policy of the Laboratory on industry Dr J A Pople took up his post as superintendent of the Basic Physics Division on October 1 , work on the application of magnetic resonance to the study of the structure and properties of materials, on the physics of high polymers, and on the study of free radicals, is to be commenced in that Division

During 1958, sixteen scientific officers and twenty-three experimental officers were newly appointed, but although these represent record numbers there was no net gain in the total staff The hope is expressed in the annual report that foreign scientists will be attracted to come and work at the Laboratory for a few years as Research Fellows, and that more firms will second staff for periods of work at the Laboratory Contact with the universities was maintained, but no details of any extra-mural contracts with universities are given in the report Six members of university staffs were appointed as vacation consultants during the summer months, and nineteen vacation students worked at the Laboratory

Two open days were again held, and of the 7,900 people invited, 3,250 attended Two international symposia were held during the year The ninth in the series, which took place during June 4–6, dealt with the physical chemistry of metallic solutions and intermetallic compounds, and the tenth, on "The Mechanization of Thought Processes", during November 24–27, evoked such considerable interest that the attendance had to be limited to the two hundred who could be accommodated The proceedings of the symposium on visual problems of colour, held in September 1957 , No 19 in the series of Notes on Applied Science entitled "Signal Generators, Attenuators, Voltmeters and Ammeters at Radio-Frequencies" , and a second volume, "Tables of Everett Interpolation Coefficients", in the series of NPL-Mathematical Tables, were published during the year In addition to a full programme of lectures, talks and discussions, in which the staff have participated, there have been several sound and television programmes based on work and tests carried out at the Laboratory A transportable NPL cæsium atomic-clock was included in the exhibition "Pendulum to Atom", organized by the British Horological Institute, and the Laboratory provided items for display at the Physical Society Exhibition, the Gauge and Tool Exhibition, the Royal Society soirée, and an exhibition for freshmen at St John's College, Oxford

The Lord President of the Council, Lord Hailsham, visited the Laboratory on June 5, and the chairman of the Council for Scientific and Industrial Research, Sir Harry Jephcott, on July 17 On February 26, a sub-committee of the Select Committee on Estimates inspected the Laboratory and appeared generally satisfied with the work being done, but expressed concern at the possibility of overlap of work and facilities between the Ship Division of the Laboratory and the Admiralty in relation to research on hull and propeller design There is formal liaison between the two establishments through the Froude Ship-Research Sub-committee, and informal liaison between the superintendent of the Division and senior officials in the Admiralty

A building plan for the long-term development of the Laboratory site is being considered in consultation with the Ministry of Works, and a centre, with lecture, conference and restaurant facilities, has at long last been authorized A new physics building and a building properly equipped for the mechanical working of difficult materials have been included in the 1959–64 proposals Reference is also made to the Ship Hydrodynamics Laboratory at Feltham [which was opened by the Duke of Edinburgh on October 19, see p 926 of this issue of *Nature*]

YELLOWSTONE PARK EARTHQUAKE

ON August 18 an earthquake occurred at 06h 37m 13s G M T from an epicentre near the western boundaries of Yellowstone National Park (epicentre lat 44½° N , long 111° W) The earthquake had a magnitude of 7 1 or rather greater on the Richter Scale The shock appears to have had a normal depth of focus Most damage appears to have been caused by the earthquake near the Hebgen dam in south-western Montana The dam is built at an altitude of 6,000 ft and holds up a lake some 37 miles long in a narrow canyon, through which flows the Madison River The dam is 87 ft high and 718 ft long In addition to cracking parts of the base of the floor of the lake and producing minor cracks in the earth and rock section of the dam, the earthquake started a huge wave in the lake, which threatened further damage Fortunately, the wall held fast The surge of water in the lake and canyon is reported to have caused an air blast which stripped the clothing from one person

Some seven miles below the dam, landslides from an 8,000 ft high mountain blocked the road and the river. The road and the surrounding countryside were severely fissured. Roads leading into the western side of Yellowstone Park were closed Perhaps two hundred people, including ranchers, campers fishermen and tourists in about fifty cars, were trapped between the landslide and the lake Ten people are reported to have been killed and sixty injured Telephones and electric power installations were out of action Buildings shifted on their foundations, chimneys fell and fuel pumps toppled over

The elastic waves of the earthquake were recorded by seismographs at observatories throughout the world At Kew Observatory the provisional readings are

eP	06 hr	48 min	11 sec	G M T	
iS	06 hr	57 min	13 sec	G M T	
MH	07 hr	18 min	00 sec	G M T	amplitude 570μ
F	12 hr	00 min	00 sec	G M T	

In the past the regions most affected seismically in this part of the United States have been east of Helena, Montana (lat 46° N , long 111 2° W), and north-east of the centre of Helena (46 6° N , 112° W)

Table 1 AFTERSHOCKS OF THE YELLOWSTONE PARK EARTHQUAKE OF AUGUST 18 (ALL DURING AUGUST)

Initial day and time (G M T)				Epicentre		Magnitude Richter Scale
Day	Hour	Minute	Second	Lat (° N)	Long (° W)	M
18	07	54	32	45	111	—
18	15	26	06	44½	111	6½
19	04	04	03	45	111½	6
19	19	06	29	45	111 4	—
19	19	43	45 7	45	110½	—
19	21	45	57	45	111½	—
20	10	59	11	45	111	—
20	19	11	27	45	111	—

From the first of these epicentres earthquakes on June 27, 1925, reached intensity 10 on the Rossi-Forel Scale and caused greatest damage at Manhattan, Logan, Three Forks and Lombard From the second location shocks in October and November, 1935, attained maximum intensity 9 on the Rossi-Forel Scale However, minor shocks of intensity 4–5 (R F Scale) from an epicentre in Yellowstone National Park, Wyoming (44° N , 111° W), occurred at various times from August 24 to December 22, 1930 In 1947 (November 23) at 09h 46m 05s G M T a shallow focus earthquake from an epicentre 44¾° N , 111¾° W reached a magnitude 6¼ on the Richter Scale Earthquakes are always liable to recur at or near old epicentres

Aftershocks of the earthquake of August 1959 so far listed by the United States Coast and Geodetic Survey are given in Table 1, although smaller shocks are said to have occurred at intermediate times

E TILLOTSON

A THEORY OF AGEING

THE theory of ageing put forward by Szilard[1] refers explicitly to mammals It is the purpose of the present communication to point out that this theory cannot explain ageing in *Drosophila*, since it is inconsistent with two experimental observations This of course does not prove that it cannot explain ageing in mammals , but reasons will be given for doubting that it does so

Szilard postulates the random occurrence of 'hits', each hit rendering ineffective the genes of a whole chromosome, or perhaps of a large segment of a chromosome A cell becomes ineffective either when two homologous chromosomes have each suffered a hit, or when one of a pair of homologues has suffered a hit, and the other carries an inherited 'fault' By a fault is meant a recessive gene which in homozygous condition renders the cell inviable, or incapable of performing a necessary function in the adult organism Death occurs when some predetermined fraction of the cells initially present is in this way rendered ineffective , Szilard suggests that this fraction is of the order of 2/3 to 11/12

It is a direct consequence of this theory that, in the author's words "The main reason why some adults live shorter lives and others live longer is the difference in the number of faults they have inherited" This is the first consequence of the theory which is contradicted by observations on *Drosophila* In so far as differences in adult longevity are genetically determined, by far the largest differences are those between inbred and outbred individuals[2,3] F_1 hybrids between inbred lines live for longer than do the parental lines (sometimes for twice as long) Outbred and genetically variable wild populations have approximately the same expectation of life as do F_1 hybrids Now inbreeding increases the proportion of loci at which individuals are homozygous An individual which survives for an appreciable time as an adult cannot, by definition, be homozygous for a fault Therefore inbred individuals which survive to become adults, and which do not die immediately after emergence, are not homozygous for faults at any loci, and would be expected to be heterozygous for faults at fewer loci than are members of outbred wild populations If two inbred lines are crossed, the F_1 hybrids would be expected to carry a load of faults intermediate between the loads carried by the parental lines Thus according to Szilard's theory, inbred lines should have a higher expectation of life than wild populations, and F_1 hybrids between inbred lines should be intermediate between their parents Neither of these predictions is in fact true

Further, since males have only a single X chromosome, any hit on that chromosome in a male would render the cell inviable, whereas in a female not heterozygous for a sex-linked fault both X chromosomes must be hit before a cell becomes inviable Therefore females should live longer than males This again is not the case in *D subobscura* In some strains females do live longer than males, but in other strains, both inbred and outbred, the reverse is true This point is particularly telling since in *Drosophila* the sex chromosomes account for about one-fifth of the total chromosome material

The other group of facts which are inconsistent with the theory concern the rate of ageing at different temperatures[4] Female *D subobscura* of a particular strain have an expectation of life of about 56 days at 20° C and of 18 days at 30 5° C The changes responsible for death at 30 5° C are not repaired or reversed in individuals kept for a time at 20° C Consequently the changes responsible for death at both temperatures can properly be regarded as ageing processes If these processes were, at each temperature, those postulated by Szilard, differing only in the rate at which hits occur, it follows that individuals kept for an appreciable time at 30 5° C should have, when returned to 20° C , an expectation of life at that temperature lower than that of individuals of the same chronological age not previously exposed to 30 5° C In fact, exposure to 30 5° C for periods of the order of half the expectation of life at that temperature does not alter the further expectation of life at 20° C of males, and significantly increases that of females

Hence, if, despite the genetic evidence to the contrary, we assume that ageing at 20° C is due to random hits on chromosomes, then ageing at 30 5° C cannot be explained by the same process proceeding at a higher rate In other words, either at 20° C or at 30 5° C ageing must be due to a process different from that postulated by Szilard , it is possible, and in my view likely, that such a process is not primarily responsible for ageing at either temperature

It is perhaps unreasonable to criticize a theory intended to explain ageing in mammals by quoting observations on insects Unfortunately the temperature experiments cannot be repeated on a homoiotherm But there is some evidence[5] in mice, as well as in *Drosophila*, that inbred individuals do not live as long as outbred ones In addition to this purely observational point, there is one more general reason why Szilard's work has made a theory of ageing by somatic mutation less, and not more, promising than it had previously appeared to be It is assumed that the 'target' is a whole chromosome , a 'hit' renders ineffective all the genes carried by that chromosome This assumption is made because, as Szilard shows, if it were assumed that the target were an individual gene, it would be necessary also to assume that each individual carried a load of faults so high as to be inconsistent with the known fertility of consanguineous marriages There are events, particularly mitotic errors and chromosome breakages, which would deprive cells of whole chromosomes or of large segments of chromosomes, but they do not seem likely to be common enough to be the main cause of ageing Most biologists would be happier with a theory which assumed as the unit event a hit on a gene, using the word gene here to refer to a functional unit or cistron Perhaps the most important thing Szilard has done is to show that such a theory, at least in its simplest form, would run into difficulties

J MAYNARD SMITH

Department of Zoology,
University College,
London, W C 1

[1] Szilard, L , *Proc U S Nat Acad Sci* , 45, 30 (1959)

[3] Maynard Smith, J , *J Genet* , 56, 227 (1959)
[4] Maynard Smith, J , *J Exp Biol* , 35, 832 (1958)
[5] Muhlbock, O , *CIBA Colloquia on Ageing*, 3, 115 (1957)

ALL the observations quoted by Mr Smith in his interesting communication relate to fruit flies and they fall into two classes observations which we may expect to be able to duplicate in the case of mammals and those which we may not Since I do not propose to discuss here whether the theory might or might not be extended to insects, I am primarily concerned with the former of the two classes

Smith states that a genetically variable, 'wild', population of fruit flies has a substantially higher life expectancy than inbred, fairly or wholly homozygous, strains derived from it He also states that the F_1 hybrid, obtained by crossing two different inbred strains, has a substantially higher life expectancy than the two inbred strains themselves Smith holds that these findings are not compatible with the theory of ageing that I proposed

It is probably true that the observations quoted above could be duplicated with mammals and I am quite prepared to accept this thesis for the sake of argument As I shall presently show, however, my theory does not preclude that the homozygous inbred strains may have a substantially smaller life expectancy than the wild type strains Further, the theory demands that the life expectancy of the F_1 hybrid be appreciably higher than that of the wild type strain, if the wild type strain carries a substantial number of faults In order to see this, we may consider the following

At present there is no evidence that a gene may be responsible for anything except for the production of a specific protein molecule which might be endowed with a specific enzymatic activity In a wild population, a given gene may be present in the form of a variety of alleles and the corresponding enzymes may differ in their turnover number For the purposes of discussion here, I shall call an allele 'weak' if the turnover number of the corresponding enzyme is small If this turnover number is very small, the allele might be a recessive lethal A completely homozygous strain is, of course, free of recessive lethals, but it may contain a number of 'weak' alleles

Again, for the purposes of discussion here, I shall adopt a somewhat over-simplified picture, and shall disregard the possibility that the enzyme-levels in the somatic cells may be determined to some extent by the regulatory mechanisms of the cell through enzyme induction or otherwise On this over-simplified basis, we may then say that the somatic cells of an inbred strain, which is homozygous for a number of 'weak' alleles, are impoverished in the corresponding enzymes, so far as their biochemical activity is concerned

My theory assumes that only a small fraction of the enzymes, less than one-fifth perhaps, is important for the functioning of the somatic cells of the adult, while practically all of the enzymes may be important for differentiation and morphogenesis during the embryonic life of the individual Accordingly, we may then expect that an individual of the inbred strain (which is homozygous for a number of 'weak' alleles) may be maldeveloped, in the sense that it may have a much smaller reserve at birth than the wild type individual, with respect to a number of physiological functions Thus it is conceivable that an individual belonging to an inbred strain may die at an age at which f, the 'surviving' fraction of its somatic cells, has fallen to, say, $f^* = \frac{1}{2\ 72} \approx \frac{1}{e}$, whereas an individual belonging to the wild-type strain may die at an age at which f, the 'surviving' fraction of its somatic cells, has fallen to about $f^* = \frac{1}{7\ 4} \approx \frac{1}{e^2}$

We may compute for this case the most probable age at death, for man, from formula (14) given on p 33 of my paper (*loc cit*) which reads

$$x_r + r = \sqrt{4m\ln\frac{1}{f^*}} + \ln\frac{1}{f^*}$$

where x_r is the number of hits at death , r is the number of the inherited faults , $m = 23$ is the number of chromosome pairs and f^* is the surviving fraction of the somatic cells at the age of death

The most probable age at death, t_r, is given by $t_r = 6 \times x_r$ years

For the inbred strain we obtain t_r, the most probable age at death, by writing $r = 0$ and $\ln\frac{1}{f^*} \approx 1$ We thus obtain $t_r = 63\ 6$ years

For the wild type we obtain t_r, the most probable age at death, by writing $r = 2$ and $\ln\frac{1}{f^*} \approx 2$ We thus obtain $t_r = 81\ 5$ years The actual value for white females in the United States is $t_r = 80\ 5$ years

For the F_1 hybrid we obtain t_r, the most probable age at death, by writing $r = 0$ and $\ln\frac{1}{f^*} \approx 2$ We thus obtain $t_r = 93\ 5$ years This is 12 years more than the value for the wild type

It may thus be seen that a substantially shortened life expectancy of the homozygous, inbred strain, as compared with the wild type, need not be inconsistent with the theory. However, an increased life expectancy of the F_1 hybrid as compared with the wild type strain is a necessary consequence of the theory.

This consequence of the theory could be tested by experiments on short-lived mammals, say mice. In order to render the experiment more sensitive, one may first expose to ionizing radiation a population of wild type mice over several generations and may thereby increase the number of faults in the population. Starting with such a 'wild' population, enriched in faults, one would then select two unrelated families and derive from them two inbred homozygous strains. The theory demands that the F_1 hybrid of these two inbred strains should live appreciably longer than the population from which the two families were selected. Given a suitable opportunity, I propose to arrange for experiments of this sort. A negative result might well prove fatal for the theory.

I should perhaps add at this point that the observed differences in the life expectancy of the male and the female do not provide a usable criterion for the validity of the theory because f^*, the 'surviving' fraction of the somatic cells at death, might differ appreciably for the male and the female.

Smith cites a rather peculiar effect of the temperature on the life expectancy of the male and the female in *D. subobscura*. It seems to me that any future theory of ageing that may be generally applicable to insects would be put to an unduly severe test, were one to demand that it account for this particular effect.

Because the theory of ageing that I proposed makes quantitative predictions, it is capable of being disproved by experiments and, sooner or later, such might be its fate. At present I am not aware, however, of any valid observations which contradict this theory. In these circumstances, I am not at present disposed to agree with the appraisal of the theory implied in the last paragraph of Mr. Smith's communication.

CROSS-LINKING OF DEOXYRIBONUCLEIC ACID IN SPERM HEADS BY IONIZING RADIATIONS

By Dr. P. ALEXANDER and Dr. K. A. STACEY

Chester Beatty Research Institute, Institute of Cancer Research, Royal Cancer Hospital,
London, S.W.3

IRRADIATION with X-rays of deoxyribonucleic acid in dilute aqueous solution leads to a reduction in the size of the molecule due to attack by hydroxyl radicals[1]. Irradiation of the solid acid as the sodium salt was claimed by us to reduce the molecular weight[2] and we wrongly concluded (see below) that ionizing radiations, whether acting directly or indirectly via free radicals from water, produce breaks in the main chain. Since *in vivo* deoxyribonucleic acid is conjugated with protein, nucleoprotein obtained from the sperm of fish was irradiated and attempts were made to isolate the deoxyribonucleic acid so as to measure its molecular weight and to see if its radiosensitivity was affected by the presence of proteins. Sperm heads were chosen for these experiments since they contain essentially only deoxyribonucleic acid and protamine. They can be prepared without denaturation as they take up only a few per cent of water and no break up of the native configuration occurs due to swelling. After the nucleoprotein complex has been dissociated in 2 *M* sodium chloride, deoxyribonucleic acid can be isolated in a very pure form (less than 0.1 per cent of protein contamination) by precipitating the protamine by the usual procedure[3] with an anionic soap, sodium dodecyl sulphate. The detergent–protamine complex is removed by centrifugation at 20,000*g* for 30 min. If the sperm heads are obtained from viable sperm by cytolysis at temperatures below 4° C., the recovery of deoxyribonucleic acid is quantitative (better than 95 per cent).

Following irradiation by 20,000–1,000,000 rads with 1-MeV. electrons from a Van de Graaff machine, the sperm heads dissolved apparently completely in 2 *M* sodium chloride, but after the removal of the protamine complex it was found that a substantial fraction of the deoxyribonucleic acid had been lost. In this dose range, no deoxyribonucleic acid was lost if the solution in 2 *M* sodium chloride was centrifuged at 20,000*g* for 2 hr. It was found that the loss of deoxyribonucleic acid was related to the dose as shown in Fig. 1. No significant difference was found between sperm-heads from salmon, trout and herring, and moreover, the same effect was obtained if viable whole sperm were irradiated in their seminal fluid and the nucleoprotein isolated after irradiation.

Evidence for Cross-linking

A possible reason for the loss of deoxyribonucleic acid on the addition of the detergent is that some of the protamine is chemically linked by the radiation to the deoxyribonucleic acid so that it, too, is involved in the detergent-complex[4]. But all attempts to demonstrate such a combination have failed. Thus the deoxyribonucleic acid was precipitated quantitatively from the dispersion of sperm heads in 2 *M* sodium chloride by the addition of a polyvalent cation, lanthanum chloride, and the precipitate analysed for protein by paper chromatography. No differences could be detected between the control and irradiated samples though the latter 'lost' 30–50 per cent of their deoxyribonucleic acid on the addition of the detergent and neither contained more than 0.5 per cent protein. The best evidence that there was no combination with protein was obtained by isolating the deoxyribonucleic acid by ultracentrifugation. In a preparative 'Spinco' the deoxyribonucleic acid from a solution of sperm heads in 2 *M* salt (concentration of deoxyribonucleic acid 0.03 per cent)

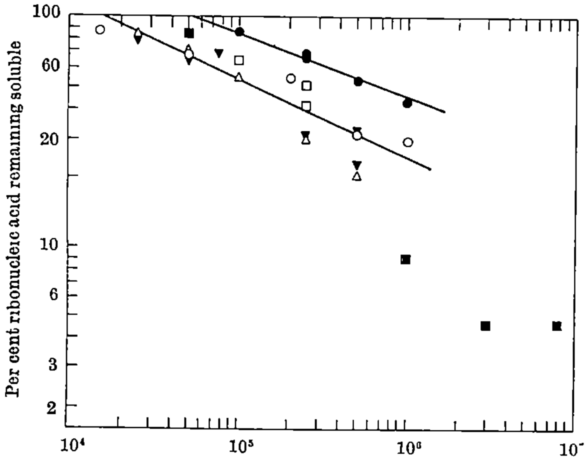

Fig 1 Effect of 1 2-MeV electrons on the recovery of soluble deoxyribonucleic acid from nucleoproteins -■- and -□-, Different preparations of salmon sperm heads, -○-, trout sperm heads, -▼-, nuclei from herring testes, -△-, viable trout sperm, -●-, 'reconstituted' nucleoprotamine fibres from trout sperm heads

was completely spun down after 15 hr at 35,000*g* The pellet of deoxyribonucleic acid was dissolved in water and then respun in 2 *M* salt under the same conditions This was repeated twice and the final pellet of deoxyribonucleic acid contained less than 0 1 per cent protein, according to the sensitive chromatographic technique of analysis developed by Kirby[5] No difference in the protein content could be detected between deoxyribonucleic acid prepared in this way from irradiated and unirradiated sperm

However, the solubility behaviour of the pellets of deoxyribonucleic acid obtained by ultracentrifugation is changed by irradiation and this provides evidence for the mechanism by which part of the deoxyribonucleic acid is removed by soaping after irradiation While the control samples dispersed completely in 0 1 *M* sodium chloride, the deoxyribonucleic acid pellet from irradiated sperm heads contained some deoxyribonucleic acid in gel form which could be removed by spinning at 20,000*g* for 3 hr The amount of deoxyribonucleic acid spun out under these conditions increases with radiation dose and is, within experimental error, equal to the soaping loss This gel component separated from irradiated sperm heads by centrifugation is not made soluble by the addition of trypsin, which digests protamine very rapidly

These results can be interpreted as showing that on irradiation some of the deoxyribonucleic acid has been cross-linked to form a very loose gel-like network which is so highly swollen in water that it is not spun out in a short time by centrifugation at 20,000*g* but is scavenged by the very flocculent precipitate produced by the addition of sodium dodecyl sulphate to 2 *M* sodium chloride After very high-speed centrifugation this material is compacted and can be removed by ordinary centrifugation at 20,000*g* Irreversible behaviour of this type is to be expected from very lightly cross-linked gels This interpretation is further supported by the fact that after very large doses (that is, greater than 3 × 10^6 rads), deoxyribonucleic acid gel is removed by centrifugation at 20,000*g* presumably because the swelling has been reduced by additional cross-links which tighten up the network After 8 × 10^6 rads the sperm heads no longer disperse at all in concentrated salt solutions

The relationship between the amount of deoxyribonucleic acid removed by soaping (that is, the amount not behaving as gel) and radiation dose (see Fig 1) is that found for cross-linking of synthetic polymers[6] The threshold, known as the gel point, arises from the fact that a minimum number of cross-links have to be formed before any part of the material has been linked into an 'infinite' network required for it to behave as a gel Charlesby[6] demonstrated theoretically for linear polymers that at the gel point the number of cross-links equals the number of molecules present Since the cross-links are distributed statistically, some molecules will be unchanged whereas others will be involved in several cross-links, and it is these which form the gel fraction

From the simple relationship of Charlesby it is possible to calculate the energy that has to be put into the system for a cross-link to be produced from the threshold dose and the molecular weight of the polymer The weight average molecular weight of the deoxyribonucleic acid was measured by light scattering and found to be between 9 and 11 × 10^6, though there was some variation from sample to sample These high molecular weights, which are confirmed by viscosity measurements, can only be obtained by starting the preparation with viable sperm If the sperm heads are stored, deoxyribonucleic acid of lower molecular weight is obtained With a threshold of 2 × 10^4 rads and deoxyribonucleic acid having a weight average molecular weight of 10^7 (assumed to be twice the number average) a value of 40 eV per cross-link formed is obtained This shows that the cross-linking reaction is a very efficient process

From the shape of the curve relating radiation dose and gel formed, it is possible[6] in polymer systems to determine whether some breaking of chains occurred at the same time as cross-linking For this calculation the points at high doses are critical, at the same time, experimentally these are the least reliable, because they are biased by trapping non-cross-linked material within the gel network If applicable, this calculation would show that there cannot be more than one break for every four cross-links, but that there may be less The average molecular weight of the residual deoxyribonucleic acid left after the removal of gel by centrifugation at 20,000*g* is less than that of the starting material and continues to decrease with increasing dose This is in accord with cross-linking theory[6] since the deoxyribonucleic acid is polydisperse and the largest molecules will be the first to enter the gel fraction, the smaller molecules are left in the soluble fraction This drop in the average molecular weight does not imply the occurrence of chain scission

Mechanism of Cross-linking

No analytical work has been attempted to determine the nature of the cross-link that is formed between deoxyribonucleic acid molecules The possibility that they are an effect of aggregation by secondary valency forces (for example, hydrogen bonds) has been considered, but seems very unlikely in view of the general properties of the gel and the fact that it is not dispersed by the powerful hydrogen-bond breaking solvent, 4 *M* urea We do not know whether the gel-like structure is formed by molecules that are joined together by a covalent bond or by a chain-branching mechanism, involving breakage and reunion, which is called end-linking by Charlesby At the present time we use the term cross-linking loosely to denote a reaction that results in the formation of deoxyribonucleic acid with gel-like properties

A degree of order seems to be necessary for efficient cross-linking since the dose of radiation needed to produce gel in reconstituted nucleoprotamine fibres, which were obtained by diluting solutions of sperm heads in 2 *M* sodium chloride, is three times greater than that needed to gel the sperm heads, which have the same overall composition The reconstituted product is known to have an irregular structure and its composition is not stoichiometric[7] In recent experiments with Mr John Lett, evidence for cross-linking has been found even when pure deoxyribonucleic acid is irradiated as a solid Although no gel is formed, except at very high doses, the results suggest that both cross-linking and main-chain breaking occur simultaneously, but that the efficiency of the former depends very much on the nature of the sample The great preponderance of main-chain breaks found in our earlier work[2] may probably be ascribed to the fact that the deoxyribonucleic acid used was of lower quality The fact that our present samples have nearly twice the molecular weight of those used earlier supports this explanation The exact factors determining the change-over from cross-linking to degradation when the sodium salt of deoxyribonucleic acid is irradiated are now being studied, but it seems that the amount of cross-linking is very dependent upon the closeness of the packing of the deoxyribonucleic acid chains The cross-linking is due to the direct action of the radiation , the free radicals produced in the water in which the sperm heads are suspended play no part, presumably because their range is too short This was established by the fact that the cross-linking efficiency is independent of the amount of water in which the specimens are suspended and, moreover, alcohol-dried herring sperm give essentially the same result, though for experimental convenience we have preferred to irradiate suspensions

The addition of 1 per cent cysteamine to a 10 per cent suspension of sperm heads provides powerful protection, reducing the amount of cross-linking to approximately half This is not in conflict with the deduction that the action is largely direct, since protection under these conditions was first reported by Alexander and Charlesby[8] for polymers and more recently by Markovich[9] for phage If the irradiations are carried out under oxygen instead of air the amount of gel-like nucleic acid that is formed is greatly reduced The importance of packing may arise from the fact that oxygen combines with the radiation-produced reactive centre and thereby prevents it from giving a cross-link Competition by oxygen may explain why in preliminary experiments we have failed to find gel-like deoxyribonucleic acid in the nuclei of irradiated chicken erythrocytes in which the nucleoprotein is much less closely packed than in sperm heads

Biological Implications

The production of a cross-link by radiation provides a very effective way whereby one event can destroy the biological integrity of a macromolecule Even if the part of the molecule involved in the formation of the cross-link is not essential to activity, the joining of two molecules together will change the physical characteristics of the molecule profoundly Since a dose of 1,000 rads produces a cross-link in, approximately, 5 per cent of the deoxyribonucleic acid molecules present in the sperm cell, quantitatively this reaction is capable of explaining cellular effects of radiation which require doses of this order of magnitude Such a theory would appear all the more attractive since one of the predominant chemical changes produced by the radiomimetic substances such as nitrogen mustards is the cross-linking of deoxyribonucleic acid in the cell nucleus[10] The similarity of the end effects produced by radiation and the chemicals would then follow from the similarity of the chemical lesion Against this mechanism is the fact that densely ionizing radiation such as polonium α-rays and 2-MeV neutrons are about ten times less efficient in cross-linking the deoxyribonucleic acid in sperm heads than are the sparsely ionizing radiations of X-, γ- and β-rays Yet the densely ionizing radiations are much the more effective in causing delay of mitosis and cell death—*a priori* one would expect that the chemical reaction which initiates the sequence of events leading to cellular effects must also be more readily produced by the densely ionizing radiations The possibility remains that there is a qualitative difference between sparsely and densely ionizing radiations in their effect on deoxyribonucleic acid, and the very low cross-linking efficiency of the α-rays could best be explained by the simultaneous production of a nearly equal number of main-chain breaks

For the inactivation of viruses the relative effectiveness of the different radiations is in the reverse order from that found for cellular effects and in qualitative agreement with the cross-linking reaction Since the tightness of the packing of deoxyribonucleic acid appears to facilitate the formation of cross-links, it is possible that this is the reaction responsible for the inactivation of bacteriophage by ionizing radiation

We wish to thank Mr D Moore, of the Experimental Radiopathology Unit of the Medical Research Council, Hammersmith Hospital, London, W 12, for his unfailing helpfulness in irradiating our samples, and Mrs A Szwarcbort and Mr P Kopp for their technical assistance This investigation has been supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research Royal Cancer Hospital) from the British Empire Cancer Campaign, and Jane Coffin Childs Memorial Fund for Medical Research, the Anna Fuller Fund, and the National Cancer Institute of the National Institutes of Health, U S Public Health Service

CARBONIC ANHYDRASE IN THE DECIDUOMA OF THE RAT

By Dr T H JOHNSON*, Dr C LUTWAK-MANN and Prof M C SHELESNYAK†

College of Physicians and Surgeons, Columbia University, New York, Agricultural Research Council Unit of Reproductive Physiology and Biochemistry, University of Cambridge, and Weizmann Institute of Science, Rehovot, Israel

ALTHOUGH extensive investigations have been made of various enzymes in placental tissue, latively little attention has been paid to the nzymes of the experimentally induced decidual ssue, that is, the deciduoma

Deciduomata offer an excellent opportunity for search on the maternal components of the placenta, pecially during the earliest phases of development, nd also in embryo-free uteri Nevertheless, the nly enzyme studied hitherto in detail in deciduoatous tissue is the histaminase[1], which has been emonstrated as characteristic of the maternal ortion in the placenta of man, rabbit and rat The esence of certain other enzymes in the deciduoma as indicated but results were only reported in mmary[2]

Carbonic anhydrase is another typical placental zyme[3] Its presence was first detected in the ammalian female reproductive tract in the endoetrium of the progravid rabbit[4] Investigations of s distribution showed that although the occurrence carbonic anhydrase in the endometrial mucosa is nited to relatively few species, it is invariably sociated with the placenta of mammals, it has en located in the maternal portion of the placenta large domestic animals, carnivores, laboratory dents and insectivores[5]

Since experimentally induced deciduomata are ucturally and functionally analogous to the cidual portion of the placenta proper, it was of terest to examine the induced decidual tissue for rbonic anhydrase For several reasons the rat erus is specially suitable for such a study The endometrium contains negligible amounts of rbonic anhydrase during œstrus, and the content this enzyme does not increase in response to ogesterone treatment[3] This is in contrast to the bbit endometrium where the response to progestere, as expressed by an increased content of carbonic hydrase, is so spectacularly characteristic that it ms the basis of an assay for luteoid potency[6] ice the rat does not show a comparable progestere-conditioned rise in carbonic anhydrase content, y increase in enzyme content found as the result inducing decidualization can be safely ascribed the presence of deciduomatous tissue Furtherre, recent studies[7–11] offer various techniques for uction as well as suppression of deciduoma in rat

This investigation was carried out to determine ether carbonic anhydrase is present in the decioma of the rat, if so, how early in the development the deciduoma the enzyme becomes detectable, ether the enzyme activity, if present, is dependent on the method of deciduoma induction, and finally, whether the suppression of the development by histamine antagonism, or by disturbance of the hormonal equilibrium, is reflected by the level of carbonic anhydrase activity

The enzyme-assay technique was essentially the same as described earlier[3] No attempt was made to dissect the deciduoma from the uterine wall, the results were expressed as enzyme units (E U) per gram entire uterine horn, fresh-weight Pseudopregnancy was induced in 3–4 months old female albino rats with regular œstrus cycles (stock colony, Anatomy Department, University of Birmingham), by faradic stimulation of the cervix on days of pro-œstrus and œstrus, of the cycle On the fourth day of leucocytic vaginal smears certain procedures were applied in order to induce or to suppress deciduoma formation

Four series of experimental animals were set up Series I consisted of 20 females injected intraperitoneally with 20 mgm pyrathiazine ('Pyrrolazote', Upjohn), to evoke the decidual response by systemic means[10] In series II there were 15 females which were laparotomized under ether anaesthesia on the fourth day of pseudopregnancy, the antimesometrial wall of the uterine lumen was scratched along its length with a burred needle to produce in these animals the typical deciduoma induced by trauma Series III included 10 females, laparotomized as above, the endometrium in both uterine horns was traumatized, but the lumen of one horn in each rat was instilled with 0 1 ml of saline solution containing 1 mgm of the anti-histaminic, diphenhydramine hydrochloride, to suppress the decidual development Series IV consisted of 10 females which were given intraperitoneally 20 mgm pyrathiazine, this being followed immediately by a subcutaneous injection of 1 mgm 'ergotoxine complex' (made up of ergocristine, ergocornine and ergocryptine methanesulphonate, 1 1 1, in 50 per cent ethanol), which has been previously shown[7,9] to prevent the formation of deciduoma by disturbing the hormonal balance In all four series the uterine weights were recorded, and the horns used for enzyme assay, at 24, 48, 72 or 120 hr, respectively, after the termination of the procedure provoking deciduoma, groups of 4 animals being used at each stage in series I, 3 in series II, and 2 each in series III and IV

It was found that carbonic anhydrase is undoubtedly present in the rat deciduoma The values established were low (ranging from 2 to 12 E U /gm) as compared with the progestational endometrium of the rabbit (up to 100 E U /gm), but they were of the same order as those obtained for the rat maternal placenta (10 E U /gm)

The findings relating to the different experimental techniques used for induction (series I and II) and suppression (series III and IV), respectively, of the decidual reaction can be summarized as follows.

Josiah Macy Fellow 1957–58, on leave at the Department of tomy, University of Birmingham

Sir Simon Marks Fellow, and University Research Fellow, 1957–58, eave at the Department of Anatomy, University of Birmingham

Carbonic anhydrase activity in the deciduoma appeared irrespective of the type of inducing agent The presence of the enzyme was evident already at 24 hr after induction, and it was still demonstrable in deciduomata 120 hr old When the decidual response was suppressed, whether by local application of an antihistaminic drug, or alternatively by interference with the hormonal equilibrium, as in the rats treated with ergotoxin, no measurable carbonic anhydrase activity was detected in the uteri

Early cellular evidence of decidualization appears as increased diploid activity, this can be demonstrated about 18–20 hr after stimulation[8] Other, probably even earlier, signs of response include changes in uterine vascularity The appearance of carbonic anhydrase is therefore consistent with the morphological signs of onset of the decidual development It is at present difficult to account for the fact that whereas there is a remarkable shift in decidual weight, from less than 5 per cent of the uterine mass to 6–7 times the initial weight of the whole uterus, yet the concentration of carbonic anhydrase, in terms of E U /gm uterine horn, remains fairly constant throughout the 120 hr of the experimental period However, it is probable that further analysis of a larger number of specimens and over a more extended period, preferably coupled with a histochemical identification of the cellular elements responsible for carbonic anhydrase activity, would help to resolve this problem

TRANSMISSION OF A VIRUS TO STRAWBERRY PLANTS BY A NEMATODE (*XIPHINEMA* sp.)

By ASHARFI JHA and Dr A F POSNETTE
East Malling Research Station, Kent

LISTER in 1958[1] described symptoms shown by diseased strawberry plants (var Cambridge Favourite) which he found to be infected with the raspberry yellow dwarf virus* of Harrison[2] These symptoms closely resembled those of a virus disease reported earlier that year at East Malling[3] affecting a range of cultivated strawberry varieties (including Cambridge Favourite) known to be tolerant to the usual (aphid-borne) crinkle virus complex, and tentatively referred to as yellow crinkle

In subsequent work at East Malling under a Colombo Plan Fellowship (A J) the causal virus of yellow crinkle and of mosaic[4] was transmitted by mechanical inoculation from plants of a number of stolons from the 'healthy' plants in the inoculated strawberry varieties, including Cambridge Favourite, to a wide range of herbaceous plants, including *Petunia hybrida* Vilm and *Chenopodium amaranticolor* Coste and Reyn One of these isolates, in *Petunia hybrida*, derived from a Cambridge Favourite strawberry plant showing typical symptoms, was successfully transmitted back to healthy plants of the same variety by mechanical inoculation Finally, cross-protection and serological tests of these isolates with authentic raspberry yellow dwarf virus and antiserum (supplied by the Scottish Horticultural Research Institute) indicated a close relationship with the latter virus

Soil transmissibility was confirmed experimentally when healthy plants of Cambridge Favourite strawberry and *Petunia hybrida* were potted in soil collected from contiguous strawberry plantations (*a*) known to be infected with yellow crinkle and (*b*) free from any symptoms of such infection Plants grown in the former afterwards developed symptoms, whereas those in the latter remained apparently healthy

In view of the conclusion of Hewitt *et al* [5] that a nematode, *Xiphinema index*, was a vector of the soil-borne fan-leaf disease of grape vines in California, samples of soil from the diseased and from the healthy strawberry plantation sources indicated as (*a*) and (*b*) above were compared for their nematode content with a Seinhorst elutriator In addition to certain species commonly found in Great Britain and present in both soils, a species of *Xiphinema* (originally determined as *X index*[6] but now known to be an undescribed species) was identified but only from the soil of the plantation infected with raspberry yellow dwarf virus The results of two experiments on the role of this nematode in the transmission of this virus to strawberry follow

In these experiments healthy Cambridge Favourite strawberry plants were grown in nematode-free soil in pots situated in an insect-proof glasshouse, the control and inoculated series being isolated from each other in adjacent compartments In the first experiment a healthy and an infected plant were established (with intermingled roots) in each pot, whereas in the second no infected plants were used

As it was thought that soil texture might have some effect on the survival of the nematodes to be added, the soil used throughout both these experiments was collected from the plantation of apparently healthy strawberry plants, that is, (*b*) above Healthy Cambridge Favourite strawberry plants grown in this soil prior to heating it remained healthy Samples of this soil were then maintained at approximately 60° C for ½, 1 and 1½ hr , respectively, to kill all nematodes present, and subsequent examinations for nematodes after three days, and again after three weeks, of storage at laboratory temperature showed that none had survived these treatments. Soil for the experiments was therefore uniformly preheated for 1 hr. at 60° C. approx.

---

* Now known to be the same as *Arabis* mosaic virus Markham and Smith

For the first experiment the nematodes were extracted, on two occasions, from the soil of the infected strawberry plantation, (*a*) above, and fifty *Xiphinema* hand-picked from each extraction were added in water suspension to the soil in each pot in the 'inoculated' series, making 100 nematodes per pot in all. For the second experiment 100 nematodes from the same source were similarly added to each pot, but on one occasion only. No nematodes were added to the 'control' pots in either experiment. A stolon from each of the strawberry plants (infected and healthy) was rooted during the course of the experiments into steam-sterilized standard greenhouse compost in adjacent pots, and acted as a supplementary indicator of infection.

Both experiments were set up in the winter of 1958–59, starting in October, and from about eight months afterwards, that is, in the summer of 1959, yellow crinkle symptoms developed on certain of the stolons from the 'healthy' plants in the inoculated series and later on the parent plants themselves. Confirmatory tests were made from each plant in both experiments by mechanical inoculation to indicator plants of *Chenopodium amaranticolor* and *Petunia hybrida*, irrespective of whether that strawberry plant had itself developed symptoms. These tests of the control plants in both experiments have all yielded negative results.

Table 1

Treatments	Exp. 1 With infector plants		Exp. 2 Without infector plants	
	No. of test plants	No. of test plants infected	No. of test plants	No. of test plants infected
Soil inoculated with *Xiphinema* sp.	13	5	10	4
Control	9	Nil	5	Nil

From the results of these two experiments, summarized in Table 1, it is concluded that the presence of the added nematodes in the soil was an essential factor in the subsequent transmissions of the raspberry yellow dwarf virus to the healthy strawberry plants. The full details of this and associated research bearing on this subject are in course of preparation.

We are indebted to Dr. R. S. Pitcher of this Station for the identification of the nematodes.

MACROMOLECULAR COMPONENTS OF *CHLORELLA PYRENOIDOSA*

By PHILIP NEWMARK, JACK D. STEPHENS, JAMES B. CURRY and GAIL L. BOWER

Department of Biochemistry, University of Kansas, Lawrence, Kansas

SUBCELLULAR organelles from disrupted cells of mammalian tissues, bacteria, yeast, blue-green algae and the seedlings of pea plants have been characterized in the ultracentrifuge[1,2]. There appears to be no report on the characterization of organelles isolated from green algae. In connexion with an exploratory study by chemical means of the various nucleic acid and protein containing fractions of *Chlorella pyrenoidosa*[3], we examined the ultracentrifuge patterns obtained from actively photosynthesizing algal cells as well as from the cells of a chlorophyll-less mutant (No. *G* 11; this mutant strain was kindly sent to us by Dr. Mary Belle Allen, Kaiser Foundation Research Institute, Richmond, California), both of which we cultured on complete and on nitrogen-free media. Use of the chlorophyll-less mutant permitted us to assess the effect of loss of photosynthetic ability on the macromolecular organization of the cell. We were interested in nitrogen deficiency because of the shift in synthetic effort in nitrogen-deficient *Chlorella* from protein to fat synthesis[4], because it had been shown that nitrogen starvation in *Torula* and *Pseudomonas* produced a much greater decrease in the cellular content of nucleic acid than of protein[5], and because the 40 *S* organelles of *E. coli* were found to break down within 2 hr. after the bacterium was transferred to a nitrogen-free medium[6].

Chlorella pyrenoidosa was cultured on a modified Bristol's solution[7] of inorganic salts in air enriched with carbon dioxide. The medium for the chlorophyll-less mutant was supplemented with 1 per cent glucose. Nitrogen deficiency was produced by transferring logarithmically growing cells to the same medium minus the nitrogen (as potassium nitrate) for a 3–6-day period. The algae were harvested from the cultures by centrifugation at 3,000*g* and were washed once with a buffer (0·005 *M* magnesium sulphate, 0·005 *M* potassium dihydrogen phosphate/dipotassium hydrogen phosphate, *p*H 7·0). The paste of cells was ground for 30 min. with 4–6 times its weight of 'Carborundum' in a cold mortar and pestle. With 600-mesh 'Carborundum' 40–60 per cent of the cells were broken. Additional operations were also carried out in the cold. The 'Carborundum' was separated at 130*g* and washed four times with buffer. Intact cells, chloroplasts and large particulates were sedimented from the combined washes at 30,000*g* for 15 min. The 30,000*g* supernatant solutions were spun for 1–4 hr. at 130,400*g*, and the resulting pellets were resuspended overnight in buffer and examined in a 'Spinco' Model *E* analytical ultracentrifuge at 4–6° C.

A typical ultracentrifuge pattern from actively growing and photosynthesizing cells is shown in Fig. 1*a*. As with the pea seedling epicotyls[2], the major component has a sedimentation coefficient of

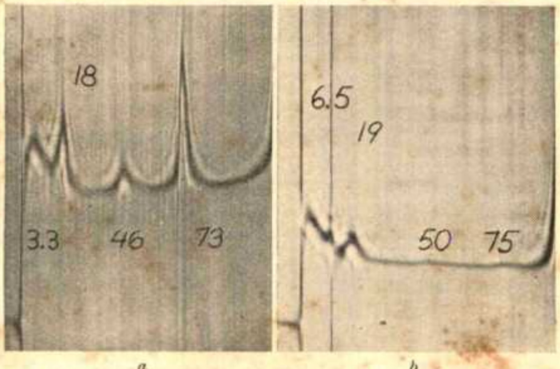

Fig. 1. Ultracentrifuge patterns of macromolecular constituents of photosynthesizing *Chlorella pyrenoidosa*. Numbers on peaks are sedimentation coefficients corrected to water at 20° C. *a*, 2-hr. 130,400*g* pellet from 4·4 gm. of normally growing cells, after 8 min. at 59,780 r.p.m., bar angle of 40°; *b*, 2-hr. 130,400*g* pellet from 5·6 gm. of 3-day nitrogen-starved cells, after 20 min. at 42,040 r.p.m., bar angle of 40°

75 *S*. The next slower peak, of sedimentation coefficient 46–50 *S*, probably corresponds to the 58 *S* dissociation product of the 75 *S* pea seedling particle. Only in preparations from stationary phase algal cultures, or when 'Carborundum' of grit smaller than 320 mesh was used as the grinding agent, did we observe another peak, 32–36 *S*, which may correspond to the second (38 *S*) dissociation product which Ts'o *et al.*[1,8,9] found in the pea seedlings. The 18–20 *S* component appears to be the Fraction I protein which has been found in the extracts of all green plants[10,11]. The 3·3 *S* component corresponds to a protein fraction that has been observed in various microbes[2]. Small amounts of a 105–110 *S* peak, though not evident in Fig. 1*a*, were observed in our preparations from time to time. This appears to be analogous to the 105 *S* peak in the pea epicotyl preparations[1,8].

Although the 75 *S* and 46–50 *S* components were degraded when incubated overnight in the cold with pancreatic ribonuclease in the magnesium sulphate/phosphate buffer, they were unaffected by pancreatic deoxyribonuclease. Overnight treatment with trypsin in the cold also largely degraded the 75 *S* organelles. In 0·01 *M* tris/0·005 *M* magnesium sulphate buffer, at *p*H 8·0, the 75 *S* component was stable for at least 3 days in the cold, but was completely degraded at the end of 5 days. In 0·01 *M* sodium ethylenediamine tetraacetate, at *p*H 7·0, it was completely degraded after 7 hr. at room temperature. These properties are similar to those of the pea seedling[9] and yeast[12] 75 *S* organelles.

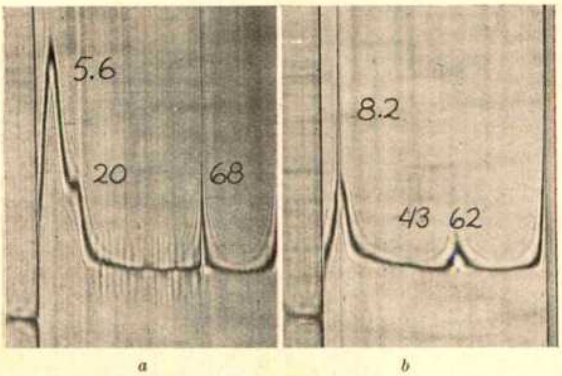

Fig. 2. Ultracentrifuge patterns of macromolecular constituents of chlorophyll-less *Chlorella pyrenoidosa*, strain *G* 11. Numbers on peaks are sedimentation coefficients corrected to water at 20° C. *a*, 2-hr. 130,400*g* pellet from 5·5 gm. of normally growing cells, after 22 min. at 42,040 r.p.m., bar angle of 50°; *b*, 2-hr. 130,400*g* pellet from 6·6 gm. of 3-day nitrogen-starved cells, after 18 min. at 42,040 r.p.m., bar angle of 50°.

The high concentration of the slowly sedimenting component (5·6–9·2 *S*) in preparations from the chlorophyll-less mutant cells (Fig. 2) is the most striking difference from the normal photosynthesizing cell preparations. In this respect the ultracentrifuge patterns of the mutant cell preparations resemble those obtained from yeast[1] and *E. coli*[2], which also require an organic source of carbon, like glucose, in their growth media.

Although Dagley and Sykes[6] found that the 40 *S* organelles of *E. coli* disappeared almost completely after the bacteria were incubated for 2 hr. on a nitrogen-free medium, Wolfe[13] and Ashikawa[1] detected appreciable quantities of 80 *S* organelles in preparations from yeast even after two days of nitrogen starvation. We could detect no significant decrease in the relative amount of the 75 *S* organelle from *Chlorella* after 24 hr. of nitrogen starvation, but after three days the size of the peak was drastically reduced (Figs. 1*b* and 2*b*). Marked reductions were also observed in the sizes of the other protein-containing peaks. On a dry-weight or per cell basis, three-day nitrogen-deficient cells contain only one-half as much nucleic acid and three-fourths as much protein as do normally growing cells; and the base composition of the residual nucleic acid differs considerably from that of the normal cells[3]. Since the greatest loss of nucleic acid is from the centrifugal fraction (1 hr. at 130,400*g*) that is primarily composed of the 75 *S* component in normally growing cells, it appears that loss of this component from the ultracentrifuge patterns in nitrogen-starved cells represents an actual loss of the functional 75 *S* organelles to the cells.

The sharp, slowly sedimenting (5·6–8·2 *S*) spike in the ultracentrifuge patterns of the nitrogen-deficient cells (Figs. 1*b* and 2*b*) most probably is deoxyribonucleic acid. It alone disappeared from the patterns after the preparations were incubated overnight in the cold with deoxyribonuclease, and it was resistant to trypsin. Sedimentation coefficients of the peaks remaining in the preparation after deoxyribonuclease digestion increased significantly because of the lowered viscosity of the solution.

After nitrogen-starved photosynthesizing cells are returned to the complete medium for 18 hr., the protein content is restored, but the ribonucleic acid content on a dry-weight basis is greater than that of normal cells. The base composition of the total nucleic acids is once more the same as that of normal cells[3]. Ultracentrifuge patterns from the 18-hr. nitrogen-restored photosynthesizing cells closely resemble the patterns from normal cells (Fig. 1*a*); but the ultracentrifuge patterns from the nitrogen-restored chlorophyll-less mutant cells again resemble those from proliferating yeast cells (Ashikawa, in ref. 1) more closely than they resemble the patterns from photosynthesizing *Chlorella* cells. These differences between the two strains of cells probably reflect the metabolic changes produced by the loss of photosynthetic ability in the mutant cells, resulting in heterotrophic rather than autotrophic nutrition.

We may conclude that the number and kinds of macromolecular organelles in the *Chlorella* cell closely reflect the nutritive conditions under which the alga is grown; further, that the changes in the macromolecular architecture of the alga may be correlated with marked changes in its chemical composition.

APPARENT OBSERVATION OF SOLAR CORPUSCULAR CLOUDS BY DIRECT CONTINUOUS-WAVE REFLEXION

By Dr. JOHN D. KRAUS and W. REED CRONE

Radio Observatory, Ohio State University, Columbus

BEGINNING at about 1.31 a.m. E.S.T. on the morning of April 15, 1959, several unique Doppler signals were recorded at the Ohio State University Radio Observatory which may possibly be due to the reflexion of continuous-wave signals from fast-moving solar corpuscular clouds passing in the vicinity of the Earth. The receiver in use at the time was a swept-frequency type with its centre frequency on 15 Mc./s. for the reception of *WWV* (Washington, D.C.). The receiver had a 1-kc./s. bandwidth and was swept about twice a second over a frequency-range of about 9 kc./s. (4·5 kc. above and below 15 Mc.). The receiving antenna was a horizontally polarized corner reflector of 1,360 sq. ft. physical aperture rotating in azimuth about 6 r.p.m. The receiver output modulated the *z*-axis of a cathode ray oscilloscope which was photographed on 35 mm. film moving about 2 cm. per min., giving a display of frequency versus time with fiducial marks along the time axis to indicate when the antenna was pointed in a reference direction (approximately south). Except for the swept-frequency receiver and rotating directional antenna, the technique was the same continuous-wave reflexion method used at the Ohio State Radio Observatory since December 1957 for the detection of ionization induced by artificial Earth satellites[1-3]. The swept-frequency receiver had been added for the observations of any Doppler shifts of the reflected signals and the rotating antenna for the observation of the direction of signal arrival.

Fig. 1 is a photograph of the swept-frequency record obtained with the above equipment between about 1.30 and 1.36 a.m. E.S.T. on April 15, 1959. Frequency extends transversely with 15 Mc./s. at the centre and 15 Mc. minus 5 kc./s. at the top and 15 Mc. plus 4 kc./s. at the bottom. The row of dots at the top of the film are the direction fiducial marks. The central heavy trace is the 15 Mc./s. signal from *WWV* (and/or *WWVH*).

Of particular interest on this record are the two strong signals which sweep rapidly from high to low frequency through the band of reception at 1.31 and 1.34 a.m. The fact that they change from high to low frequency suggests that they might be Doppler shifted signals reflected from rapidly moving ionized clouds. Beginning about 1.45 a.m. many other apparent Doppler signals were recorded on the film until about 3.25 a.m., after which all such indications disappeared. All the signals after 1.45 a.m. differ from the two of Fig. 1 in that they persist much longer, have a periodic fluctuation of several kilocycles, and have a smaller maximum frequency deviation. Fig. 2 is a typical example of one of these signals recorded about 2.35 a.m.

The signal at 1.31 a.m. has a rate of frequency-change of more than 400 c./s. per sec., and if it is a true Doppler reflexion of *WWV* must have a maximum frequency deviation of at least 20 kc. or several times as great as the receiver sweep-range. The signal at 1.34 a.m. has a lower rate of change of frequency and also appears to be quite asymmetrical, having the appearance of a segment of a Doppler curve at a considerable frequency deviation from the original frequency. Thus, this signal might have been caused by a Doppler shift of another station transmitting on a frequency greater than 15 Mc./s.

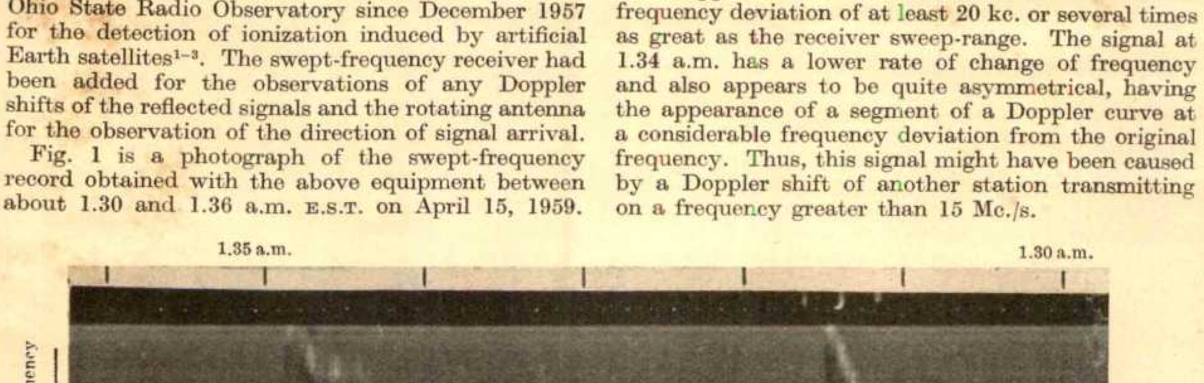

Fig. 1. Swept-frequency record of Doppler signals recorded between 1.30 and 1.36 a.m. (E.S.T.) on April 15, 1959. Frequency extends transversely with 15 Mc./s. at the centre and 15 Mc. minus 5 kc./s. at the top and 15 Mc. plus 4 kc./s. at the bottom. Time increases to the left. The dots along the top of the film are the direction fiducial marks

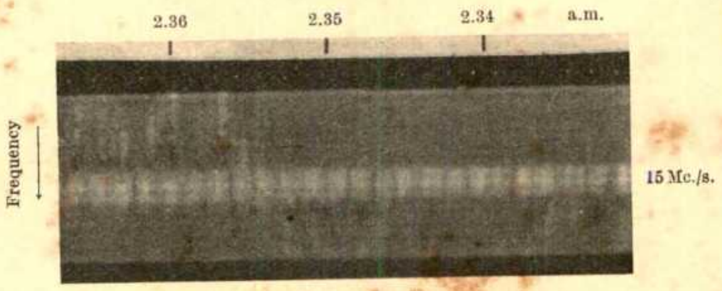

Fig. 2. Swept-frequency record of Doppler signals recorded about 2.35 a.m. on April 15, 1959. These signals show less frequency deviation but have more frequency spread and a periodic fluctuation suggesting turbulence

The limited frequency-range of the sweep system (9 kc./s.) prevents an accurate determination of the maximum frequency deviation. However, various considerations would place the maximum deviation between 20 and 80 kc./s. These values imply a velocity of the reflecting cloud of between 200 and 800 km. per sec.

It may be significant that about two days earlier a large solar flare occurred near the central meridian of the Sun. This flare reached its maximum about 0900 U.T. on April 13, 1959, and was rated of importance 3 (highest rating) by the High Altitude Observatory of the University of Colorado[4]. Material ejected by this flare travelling at an average velocity of 900 km. per sec. would have reached the vicinity of the Earth at about 1.30 a.m. (E.S.T.) (0630 U.T.) on April 15, when the first Doppler signal was observed. An average velocity of 900 km. per sec. is not uncommon for flare-ejected material, terrestrial magnetic and other effects being observed typically about two days after large solar flares. Hence, the radio reflexions on April 15 could have occurred from ionized clouds forming part of corpuscular streams ejected from the Sun by the flare of April 13, the velocity at the time of the radio observations having decreased considerably below the average value.

All the signals recorded between 1.45 a.m. and 3.25 a.m., such as shown in Fig. 2, appear to have a Doppler spread of several kilocycles, with the later signals appearing to have a greater frequency dispersion than the earlier ones. The signal in Fig. 2 has a frequency spread or dispersion of at least 4 kc./s. They also appear to possess a periodic fluctuation around a more slowly varying average frequency. This fluctuation amounts to a couple of kilocycles and is suggestive of turbulence in the clouds. The maximum deviation of the average frequency for these signals is about 4 kc./s., which corresponds to a velocity of 40 km. per sec. Hence, these signals could be interpreted as due to reflexions from slower-moving turbulent clouds following in the wake of the high-velocity cloud recorded in Fig. 1, and apparently trapped in the Earth's magnetic field.

A number of terrestrial phenomena occurred early on April 15 which also suggest the possible arrival of solar particles in the Earth's vicinity at that time. For example, the recordings of the Earth's magnetic field at the Magnetic Observatory at Agincourt, Ontario, Canada[5], show fluctuations between 1.00 and 2.00 a.m. E.S.T. with little or no variations for the 3 hr. preceding 1.00 a.m. and the 5 hr. following 2.00 a.m. The maximum increase in declination (east) amounts to about 22γ with its highest values centred about 1.20 a.m., or 11 min. before the first radio Doppler signal, compared to less than 6γ maximum variation in the adjacent 8 hr. Of particular interest is the fact that the maximum declination variation is more than twice that of the other field components. It may be significant in this connexion that an ion cloud travelling radially away from the Sun and passing near the northern hemisphere of the Earth would produce a change in the approximately east–west component of the Earth's field (declination) which would be larger than the change in the other components (north and vertical) as observed at Agincourt. The fact that the declination increase was eastward implies a cloud with a net positive charge.

The direction indications provided by the rotating receiving antenna indicate that the first Doppler signals (at 1.31 and 1.34 a.m.) were received from a generally north-western direction. This direction is consistent with that to be expected for clouds from the Sun passing by the Earth above the northern hemisphere, since as observed from Columbus clouds approaching from the Sun would be observed (in azimuth) to come from the north. The later Doppler signals (after 1.45 a.m.) show a direction of arrival which is also generally to the north with some appearing to begin toward the north-west and changing to a north-east or easterly bearing.

It is of interest to calculate the distance of the ionized clouds at their point of near approach and also their radar cross-section. Based on a frequency deviation of at least 20 kc./s. (but not more than 80 kc./s.) and a maximum rate of change of frequency of 410 c./s. per sec., a distance of at least 10,000 km. (but not more than 160,000 km.) is obtained for the initial cloud (Fig. 1). The calculated radar cross-section of this cloud is at least 100 sq. km. (but not more than about 5×10^4 times this value). For the later clouds, the maximum (average) frequency deviation is typically about 4 kc./s. and the maximum rate of change of frequency about 75 c./s. per sec. Hence, these clouds were about 2,000 km. distant at near approach and had radar cross-sections of about 0·2 sq. km. each. In order to reflect the 15 Mc./s. signals electron densities in the clouds of the order of 10^{12} per cu.m. are required. From various considerations it appears that the clouds contained positive ions, electrons and perhaps neutral matter.

The above observations are suggestive of Doppler reflexions from solar corpuscular clouds. So far as we are aware, moving solar corpuscular clouds have not previously been detected by direct radio (or radar) techniques; so if the interpretation of the results is correct this marks the first observation of its kind.

FLUCTUATIONS IN PHOTON STREAMS

By Dr. PETER FELLGETT
The Observatories, University of Cambridge, England
Dr. R CLARK JONES
Polaroid Corporation, Cambridge, Mass., U S A.
AND
Dr R. Q TWISS
School of Physics, University of Sydney, Australia

BRIEF mention was made in a previous communication[1] of the way in which photon fluctuations have been studied in connexion with the performance of detectors of radiation, particularly for the infra-red region The ability to detect small radiation signals despite the inevitable presence of noise in the device is called detectivity Milatz and van de Velden[2] were the first to recognize that a limit to the detectivity of a thermal detector is set by the spontaneous fluctuations in temperature as given by the Einstein–Fowler formula[3]

$$\overline{\Delta E^2} = kT^2 \frac{\partial E}{\partial T} \qquad (1)$$

where E is the energy in the receiver, T the absolute temperature and k the Boltzmann constant

The mean square fluctuation $\overline{\Delta n^2}$ in the density of photons in a temperature enclosure is (see ref 3)

$$\overline{\Delta n^2} = n + \frac{n^2}{N} \qquad (2)$$

where n is the mean density of photons, and N the density of Bose cells The first term in equation 2 is equal to the fluctuation $\overline{\Delta n^2} = n$ in a random set of classical particles having mean density n The second term is similarly identifiable with the fluctuation $\overline{\Delta n^2} = n^2/N$ in the squared amplitude in a random set of classical waves The total fluctuation can therefore be regarded as comprising a 'classical particle' part, n, and a 'classical wave' part, n^2/N

Lewis[4] used equation 2 to calculate the fluctuation in the energy exchanged by a black receiver with an isothermal cavity, and found the same limit to the detectivity as had been derived by Milatz and van de Velden Clark Jones[5] showed that this agreement provides a means of using equation 1 to calculate the limiting detectivity of any radiation receiver in equilibrium with an isothermal enclosure, whatever may be its spectral responsivity and whether or not its mechanism is thermal The result may be summarized by saying that in each small frequency-range the mean square fluctuation in the number m of photons affecting a detector having quantum efficiency ε is

$$\overline{\Delta m^2} = m\left(1 + \frac{n}{N}\right) \qquad (3)$$

where

$$m = \tfrac{1}{4}\varepsilon c n A \qquad (4)$$

$$n = N/(\exp h\nu/kT - 1) \qquad (5)$$

$$N = 8\pi\nu^2 d\nu/c^3 \qquad (6)$$

A is the effective surface area of the receiver, c the velocity of light, ν the wave frequency, and h the Planck constant.

These developments have led to an understanding that the detectivity of radiation receivers is subject to limitations which do not essentially depend on the particular mechanism (whether photo-emissive, photoconductive, thermal or phase-coherent), but are determined by the extent to which its wave-length responsivity causes the detector to be susceptible to the fluctuations in the ambient thermal radiation. These photon-fluctuations became of practical interest when it was found[6,7] that some of the best actual detectors of infra-red radiation had detectivities close to the limit set by equation 3 In the Rayleigh–Jeans approximation $\nu \rightarrow 0$, equation 3 also represents the ordinary Johnson noise in the radiation resistance of an antenna[6]

Photon fluctuations have acquired renewed interest with the demonstration[8] that partial coherence of visible light can be measured by means of the correlation between fluctuations in the photocurrents in two photocells The experiments have occasioned some surprise, and it has even been suggested that non-zero correlation would be contrary to fundamental quantum notions On general correspondence principle grounds, however, the properties of radiation which admittedly make fluctuation interferometry possible in the radio region[9,10] cannot just disappear at optical wave-lengths ; there must be some gradual transition through the infra-red Correlation between the signals from two coherently illuminated cells arises from the 'wave' fluctuations, and provides the only means so far known of investigating this component experimentally for visible light. The 'particle' fluctuations at the two cells are mutually uncorrelated, and act as noise tending to mask the effect which it is desired to measure The familiar transition (equation 3) in the infra-red from the predominance of 'wave' noise to that of 'particle' noise as the wave-length shortens makes it clear[1] that the 'wave' component is indeed always present, but that it becomes increasingly smothered by the 'particle' noise as the optical region is approached, so that a refined method is needed to measure it

A difficulty remained, however[1,11] Hanbury Brown and Twiss developed a theory of the fluctuation in the output of a photocell which was based on the analysis of the detailed interaction between the photoelectrons and the radiation field It gives results consistent with the picture that photons 'arrive' at random, subject to the probability of 'arrival' being proportional to the instantaneous value of the square of the classical electric vector of the incident radiation A statistical approach of this kind had been abandoned in earlier work on fluctuations affecting radiation detectors because of the apparent difficulty of making the arguments rigorous[12] The predictions of this theory are in agreement with the correlation found experimentally by Hanbury Brown and Twiss in the fluctuation interferometer Applied to the fluctuation in the radiation exchanged by a receiver with an isothermal enclosure, however, the theory apparently gives

$$\overline{\Delta m^2} = m\left(1 + \frac{\varepsilon n}{N}\right) \qquad (3a)$$

where ε is the emissivity of the receiver The 'wave' noise in this equation is smaller by a factor ε than that given by equation 3 If equation $3a$ were correct under these conditions, the fluctuation temperature of a grey body in thermal equilibrium with a cavity would not be the same as the temperature of the cavity A heat engine could then be arranged to work between the body and the cavity so as to give mechanical work in a *perpetuum mobile* of the second kind[1] This may be regarded as unacceptable, either because it contradicts the second law of thermodynamics, or because it conflicts with microscopic reversibility

It is central to the problem that any conflict between equations 3 and $3a$ can refer only to the behaviour in an isothermal enclosure, since although the derivation of equation $3a$ was believed to be quite general, the arguments leading to equation 3 explicitly assumed thermodynamic equilibrium It has been pointed out[12,13] that for this reason no unambiguous induction had been made from equation 3 to conditions outside a cavity This, incidentally, logically disposes of the assertion sometimes made that fluctuation interferometry outside a cavity is able to decide directly the correctness of equation 3

In considering how the difficulty can be resolved, it now seems clear that a number of the objections to the thermodynamic approach originally put forward by Hanbury Brown and Twiss[11] are invalid Thus it is not correct that detailed balancing in aged systems applies only to the energy flow itself and not to the fluctuations, as this would imply that microscopic reversibility did not hold, a consequence for which there is no justification Furthermore, the non-linear relation between the loss of heat from a thermal detector and its temperature does not significantly affect the derivation used by Jones and Fellgett The significant non-linearity is the square-law relation between the mean photon-rate and the amplitude of the classical electromagnetic wave, which implies that the fluctuation in the sum of two radiation streams is not generally equal to the sum of the fluctuations in the two separate streams This non-additive property corresponds to the 'bunching' of photons in Bose–Einstein statistics, and is represented classically by 'beats' between the component wave-amplitudes The general statistical-thermodynamic considerations on which the deviation of Jones and Fellgett is based include such effects automatically , they do not have to be taken into account explicitly, as they would, of course, in a derivation based on consideration of the detailed mechanism of exchange of radiation

On the other hand, Jones[5] and Fellgett[6], in assessing the fundamental noise-level in radiation detectors exposed to room temperature radiation, had attempted to include, as well as detectors in equilibrium, detectors in which 'active' radiation is suppressed either by cooling, as in superconducting bolometers or lead-compound photoconductive cells, or by applying an electric field to a photocell , 'active' radiation here means radiation-emitting transitions which cause a change in the output of the device, for example, the radiative return of an electron to the conduction band in a photoconductive cell To cover such cases, Jones and Fellgett assumed that the fluctuation given by equation 3 could be expressed as the sum of two independent terms, one associated with the radiation absorbed and the other with that emitted, so that only the part thus ascribed to the incident radiation would contribute to the fluctuations in the outputs of strongly cooled detectors or of photoemissive cells with voltage applied Since the derivation of equation 3 assumes equilibrium, this extension of the use of the equation could be justified only by additional physical considerations, which they attempted to supply

It now appears that this procedure is wrong, not only quantitatively but also conceptually, because it fails to take account of the possible interaction between the radiation incident on the detector and that radiated by it, and so assumes falsely that the noise in these two streams behaves additively Moreover, the recognition of this interaction enables the fluctuation theory developed by Hanbury Brown and Twiss to be applied to the exchange of radiation in a cavity in a way which agrees with thermodynamics

To illustrate this in a special case, consider the exchange of radiation between two cavities at temperatures T_1 and T_2 separated by a non-absorbing semi-reflecting mirror having energy transmission ε and reflectivity $1 - \varepsilon$ Let E_1 be the modulus of the electric vector corresponding to the radiation emitted by the T_1-region and incident at a point of the mirror, and $E_1\sqrt{(1-\varepsilon)}$ the electric vector corresponding to the radiation reflected back towards the T_1 region Similarly, let E_2 be the modulus of the electric vector corresponding to the radiation emitted by the T_2-region towards the T_1-region Since there is no coherent phase relation between E_1 and E_2, the field corresponding to the radiation transmitted by the mirror into the T_1-region can be represented without loss of generality by the vector $E_2\sqrt{\varepsilon}$ Then the difference between the rate at which energy is absorbed and emitted by the T_2-region according to classical wave theory is proportional to

$$E_1^2 - (E_1\sqrt{(1-\varepsilon)} + E_2\sqrt{\varepsilon})^2$$
$$= \varepsilon(E_1^2 - E_2^2) - 2E_1E_2\sqrt{\{\varepsilon(1-\varepsilon)\}}$$

The mean square deviation of this quantity from its mean value $\varepsilon(\overline{E_1}^2 - \overline{E_2^2})$ is

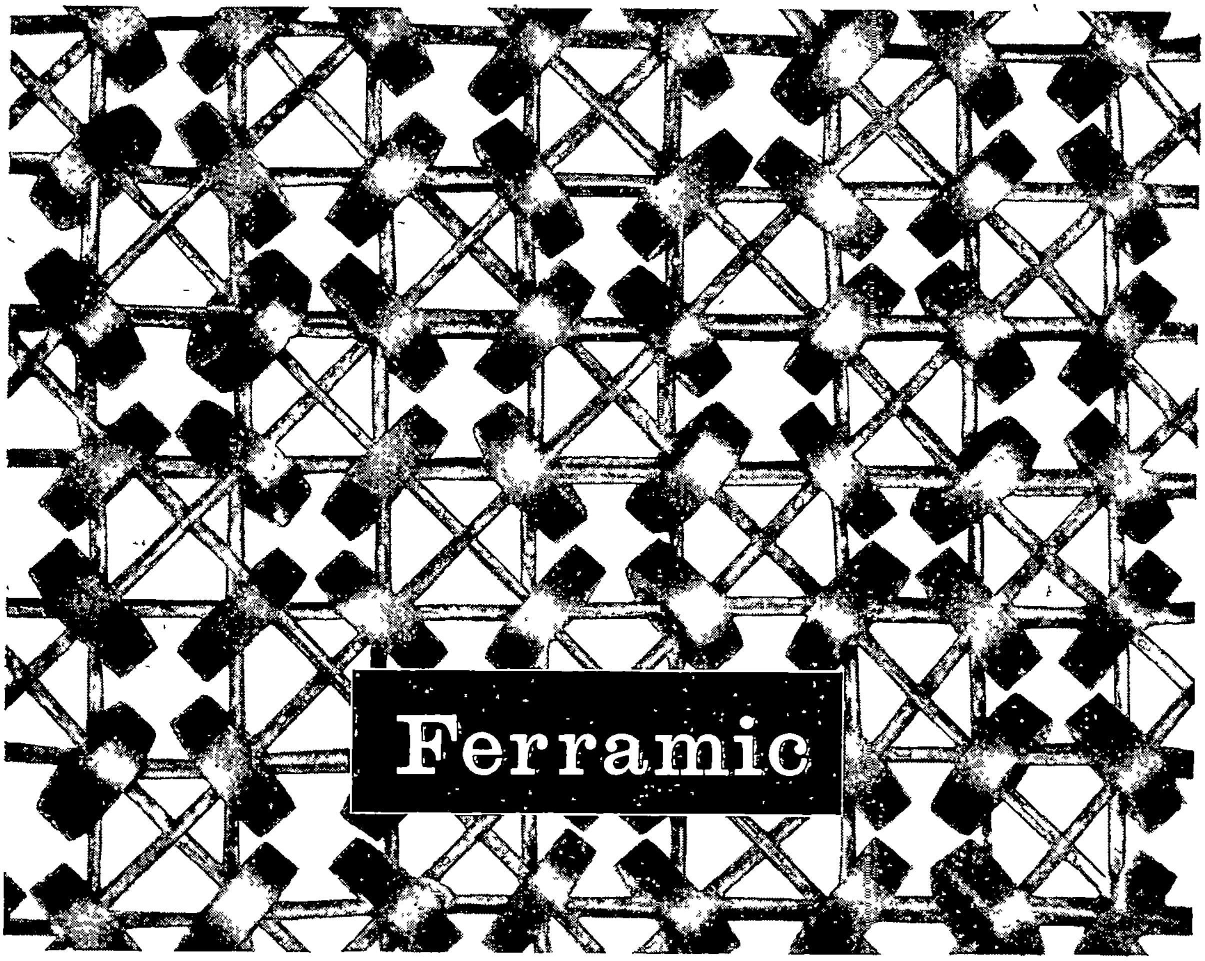
$$\varepsilon^2\{(E_1^2 - \overline{E_1}^2)^2\}_{\text{av}} + \varepsilon^2\{(E_2^2 - \overline{E_2}^2)^2\}_{\text{av}} + 4\cdot(1-\varepsilon)\,\overline{E_1^2}\;\overline{E_2^2}$$

under the condition $\overline{E_1E_2} = 0$ If E_1, E_2 have Gaussian probability distribution, $\{(E^2 - \overline{E}^2)^2\}_{\text{av}} = 2(\overline{E^2})^2$ and the expression reduces to

$$2(\varepsilon^2I_1^2 + 2\varepsilon(1-\varepsilon)I_1I_2 + \varepsilon^2I_2^2) \qquad (7)$$

where $I_1 = \overline{E_1^2}$, $I_2 = \overline{E_2^2}$ The fluctuation in the radiation exchanged through a finite area of the mirror is equal to the product of this expression with a factor which can be evaluated in the usual way by considering the variation of the coherence in space and time

The T_2-region and the mirror can together be regarded as constituting a body with emissivity ε



FERRAMIC is a registered trade mark

A ferrite to remember

Cores made of Plessey 'Ferramic' material, only ·050″ in diameter, make possible the intricate memory planes used in modern computer design The electrical properties of these microscopic cores have to be critically accurate and 'Ferramic' readily meets the demands

Other grades of 'Ferramic' are also being made in large quantities for many components requiring a core material of the highest efficiency —television transformers, scanning coils and aerial rods among them

Designers still seeking a core material which will realise the performance they want, at an economical price, are invited to write for data sheets on available grades of 'Ferramic'

Shown is an enlarged section of a typical Plessey memory plane
Each core is only 050″ in diameter

You Can't Lose When You Specify Sigma

Sigma Reagent Stability Guarantee

As we all know, many Reagents used in both research and clinical laboratories are highly unstable Some require storage below 0° C, others require thorough desiccation, some will lose activity or purity within short periods of time regardless how stored Shipping itself is hazardous All of this results in substantial losses to the user Now, in cooperation with laboratories the world over, Sigma Reagents are guaranteed against such hazards Any item routinely offered by Sigma will be replaced free of all charges (including postage) if found to be unsatisfactory at any time Simply return the remaining material with your comments and an equivalent quantity will go forward to you promptly at no charge

As always, you must be completely pleased with the quality of our preparations, or there will be no charge

Regardless of how it happens — if it is not good, send it back for replacement!

SEND YOUR ENQUIRIES TO

exchanging radiation with the T_1-region For example, it may represent a detector made of a material which absorbs all the radiation entering its substance but which has a dielectric constant differing from that of its surroundings so that partial reflexion occurs at its surface If $T_1 = T_2$, the average energies I_1 and I_2 radiated by the T_1- and T_2-regions are equal, and the expression 7 reduces to $4\varepsilon I^2$ The mean square fluctuation is therefore proportional to ε, and this accords with the form of the wave-noise term $\overline{\Delta m^2} = mn/N$ in equation 3 (since m contains ε as a factor, see equation 4) By contrast, if $T_1 \gg T_2$, I_2 can be neglected and expression 7 tends to $2\varepsilon^2 I^2$ This shows that the mean square fluctuation now varies as ε^2 in accordance with the wave term $\overline{\Delta m^2} = \varepsilon mn/N$ in equation 3a

For a detector conforming to this model, the previous difficulties have now been resolved Equation 3a is seen to be correct under the conditions of the experiments made by Hanbury Brown and Twiss, namely, when the emitted radiation field is effectively zero , but not for detectors which are hot enough to radiate appreciably Equation 3 is correct when applied to the exchange of radiation between a cavity and a detector in equilibrium , but not with the extended interpretation ascribed to it by Jones and Fellgett In reaching these conclusions, it has been necessary to consider not only interaction between the absorbed and the emitted radiation, but also interactions involving both the reflected radiation and that radiation which is regarded as 'virtually emitted' if we consider the detector as an assembly of classical or quantized oscillators

It is not certain that the model is completely general The discussion given above is purely classical-wave, and a quantum-mechanical approach is needed in which stimulated emission replaces the classical wave-interference effects This method will automatically include a 'particle' term as well as the 'wave' term, and may show what happens when there are competing mechanisms of absorption of radiation, one of which is 'active' in producing output from the cell whereas the others are not

Despite these limitations, it seems very plausible (to put it no higher) that equation 3 is correct generally when the detector is at the temperature of the radiation field in which it is placed , and that equation 3a becomes true in the limit when the detector is too cool to radiate appreciably The effect of these conclusions on the calculation of the limiting detectivity of radiation detectors remains to be investigated in detail

It now appears, therefore, that the discrepancy, which was pointed out in earlier publications, between the fluctuation formula derived by Jones and Fellgett on one hand, and by Hanbury Brown and Twiss on the other, was real and that it showed limitations in both methods of calculation as they were then conceived The two formulæ have now been reconciled, and each found to be correct in the circumstances for which it was originally derived, by taking account of the interaction between the incident, emitted and reflected radiation streams, the relevance of which had not previously been appreciated

By Dr C. W. McCOMBIE

Department of Natural Philosophy, Marischal College, Aberdeen

Two contradictory views on the fluctuations in the absorption and emission of photons by matter have been discussed in recent papers[1-3]. Both views agree that the mean square fluctuation, $\overline{\Delta N^2}$, in the number N of photons in a small frequency-range absorbed or emitted in unit time by a black body will exceed the value $\bar{N}$, appropriate to Poisson fluctuations, by a factor $1 + \bar{n}$ here $\bar{n}$ is the mean number of photons in one of the electromagnetic modes concerned and is given by $\{\exp(h\nu/kT) - 1\}^{-1}$ The disagreement arises when the body absorbs imperfectly According to one view[1,4,5], the fluctuations in the number of photons absorbed (or emitted) will exceed Poisson fluctuations by the factor $1 + \bar{n}$, no matter how small the fraction of incident photons absorbed This opinion claims support from the quasithermodynamic type of argument, given by Clark Jones[6] and by Fellgett[4], and generally used to establish the ultimate sensitivity limits for radiation detectors The other view[2,3] maintains that the random selection of photons for absorption tends to make the fluctuations approach a Poisson distribution more precisely, the factor $1 + \bar{n}$ is reduced to $1 + \varepsilon\bar{n}$, where ε is the absorptivity This second view is supported by detailed calculations[3,7] concerned primarily with the photon correlation experiments of Hanbury Brown and Twiss[7]

In this communication the quasithermodynamic approach will be applied to a particular model The results agree with the detailed calculations in supporting the *second* point of view, and for this model, at least, the conflict is resolved The agreement depends on taking account of the fact that, because of stimulated emission, the radiation emitted by matter depends in general on the radiation field into which it radiates the mean rate at which an atom radiates into an electromagnetic mode is proportional to $1 + \bar{n}$ (cf Heitler[8]) This effect must be allowed for whenever, as in the disagreement under discussion, $1 + \bar{n}$ is distinguished from unity The results also agree with the standard formula for the ultimate sensitivity limit of radiation detectors derived by Clark Jones and Fellgett, although, as mentioned, it has been claimed that this formula supports the *first* view This claim depends on the assumption that the mean rate at which the detector absorbs radiation from a black body radiation field with which it is in equilibrium can be equated to the absorptivity multiplied by the rate of incidence of the black body radiation on the detector · it will emerge that, because of stimulated emission effects, this equality does not hold for the model to be considered here

In the quasithermodynamic approach the system concerned is characterized by the coefficient α, where $\alpha\Delta T$ is the rate of loss of heat from the system when its temperature exceeds that of the surroundings by ΔT The basic result used is the following analogue of Nyquist's theorem when the system and its surroundings are both at temperature T, the mean square fluctuation in the energy absorbed or emitted in unit time by the system in thermal exchange with its surroundings is $\alpha k T^2$ This result reduces the calculation of the magnitude of the fluctuations to the calculation of α

The importance of considering stimulated emission can be seen very simply by considering the fluctuations for a set of very weakly absorbing and emitting atoms The photon absorption-rate will equal a constant θ_T, depending on the number, nature and temperature of the atoms, multiplied by $\bar{n}$, the mean number of photons in an electromagnetic mode in the (small) range of frequencies absorbed by the atom To determine α, we suppose the surroundings at temperature T and the atoms at temperature $T + \Delta T$ Since the atoms radiate and absorb weakly, $\bar{n}$ will have the value $\bar{n}_T$ appropriate to the temperature of the surroundings. The rate of absorption of photons will be $\theta_{T+\Delta T}\,\bar{n}_T$ and, with neglect of stimulated emission effects, the rate of emission would equal that of atoms in equilibrium with radiation at $T + \Delta T$, which must equal the rate of absorption from this radiation, that is, $\theta_{T+\Delta T}\,\bar{n}_{T+\Delta T}$ But because the atoms are actually radiating into radiation at temperature T, not $T + \Delta T$, and for a given state of the emitter the radiation is proportional to $1 + \bar{n}$, the rate of emission must be modified to $\theta_{T+\Delta T}\,\bar{n}_{T+\Delta T}(1 + \bar{n}_T)/(1 + \bar{n}_{T+\Delta T})$ Substitution of the resulting value (note that $\mathrm{d}\bar{n}/\mathrm{d}T$ can be written $\bar{n}\,(1+\bar{n})\,h\nu/kT^2$) of α in the quasi-thermodynamic result gives $\theta_T\,\bar{n}_T$ for $\overline{\Delta N^2}$ This represents Poisson fluctuations, in agreement with the second view, since the absorption is small Neglect of stimulated emission introduces an extra factor $1 + \bar{n}$, lending spurious support to the first view

The main model to be considered here consists of a large cavity filled with a tenuous gas of atoms which absorb only in a small frequency-range around ν at a rate again specified by θ_T. the walls are perfectly reflecting apart from a small opening, of area A, to the outside Radiation, which enters the cavity from the outside and re-emerges after being reflected around but not absorbed by an atom, is to be regarded as scattered Thus the model can be adjusted to represent arbitrary ε

To determine α and ε for the model, it is necessary to consider non-equilibrium situations in which $\bar{n}_{\mathrm{inc}}$, the number of photons per mode in the radiation incident on the aperture from the outside, differs from the value $\bar{n}_T$ appropriate to the temperature of the atoms The number of photons per mode in the cavity will then differ from $\bar{n}_T$, it will be supposed, however, that $\bar{n}$ has the same value, denoted by $\bar{n}_c$, for all modes of frequency ν in the cavity The value of $\bar{n}_c$ is fixed by the energy balance requirement that the net rate of emission of photons through the aperture, $(\bar{n}_c - \bar{n}_{\mathrm{inc}})\varphi$, where φ is a constant fixed by A and ν, must equal the net rate of emission of photons by the atoms, so that

$$(\bar{n}_c - \bar{n}_{\mathrm{inc}})\varphi = \theta_T\,\bar{n}_T(1 + \bar{n}_c)/(1 + \bar{n}_T) - \theta_T\,\bar{n}_c \quad (1)$$

where stimulated emission effects have been treated as before

In order to determine α the surroundings are supposed at temperature T, so that $\bar{n}_{\mathrm{inc}}$ is $\bar{n}_T$, and the atoms at temperature $T + \Delta T$ The net rate of energy loss $\varphi(\bar{n}_c - \bar{n}_T)$, evaluated to the first order in ΔT, gives α The preliminary determination of $\bar{n}_c$ follows from (1) with $\bar{n}_{\mathrm{inc}}$ and T replaced by $\bar{n}_T$ and $T + \Delta T$ The quasithermodynamic result then gives

$$\overline{\Delta N^2} = \frac{\alpha k T^2}{(h\nu)^2} = \frac{\theta_T\varphi(1 + \bar{n}_T)\bar{n}_T}{\theta_T + \varphi(1 + \bar{n}_T)} \quad (2)$$

Because of stimulated emission, ε_T, which can be regarded either as the emissivity or the absorptivity, must be defined rather precisely, but the appropriate operational definitions are clear As the emissivity, ε_T would be determined by letting the system, with the atoms at temperature T, radiate in the absence of incident radiation, and taking the ratio of the emitted radiation $\varphi\bar{n}_c$ to that from a black body of the same area and temperature, namely, $\varphi\bar{n}_T$ As the absorptivity, ε_T, would be found by increasing the incident radiation slightly above its equilibrium value, so that $\bar{n}_{\mathrm{inc}}$ exceeds $\bar{n}_T$, and taking the ratio of the net rate of absorption of radiation, $(\bar{n}_{\mathrm{inc}} - \bar{n}_c)\varphi$, to the extra rate of incidence, $(\bar{n}_{\mathrm{inc}} - \bar{n}_T)\varphi$, the values of $\bar{n}_c$ in the two cases are easily determined from equation 1 The results for ε_T agree, being given by .

$$\varepsilon_T = \frac{\theta_T}{\theta_T + \varphi(1 + \bar{n}_T)} \quad (3)$$

$\overline{N}_T$ is the mean flux of photons which, when system and surroundings are at temperature T, proceed from atoms of the gas to the outside without intervening absorption, as distinct from (*a*) photons which enter and leave without absorption, or (*b*) those which are emitted by an atom and absorbed by an atom without leaving the cavity Only a fraction $\varphi/(\theta_T + \varphi)$ of the radiation emitted by an atom will escape, the rest being re-absorbed The atoms will radiate at the rate $\theta_T\bar{n}_T$ Consequently

$$\overline{N}_T = \frac{\varphi\theta_T\,\bar{n}_T}{\theta_T + \varphi} \quad (4)$$

It may be noted that $\overline{N}_T$ exceeds $\varepsilon\varphi\bar{n}_T$, the rate of emission in the absence of incident radiation The ratio of the two, $(1 + \bar{n}_T)/(1 + \varepsilon\bar{n}_T)$, is just the stimulated emission factor corresponding to the different values of $\bar{n}_c$

According to equations 2, 3 and 4, $\overline{\Delta N^2}$ can be expressed in two algebraically equivalent forms

$$\begin{aligned}\overline{\Delta N^2} &= \varepsilon\varphi\bar{n}_T(1 + \bar{n}_T) \\ &= \overline{N}_T(1 + \varepsilon\bar{n}_T)\end{aligned} \quad (5)$$

The first form reproduces the result used in the theory of the ultimate limit of radiation detectors The second exhibits for this model the complete agreement between the results of the quasithermodynamic discussion and the results of the detailed approach of Hanbury Brown and Twiss

I am indebted to my colleagues, Drs E W Elcock and P T Landsberg, for their comments on this communication, and to Dr P B Fellgett for correspondence on preliminary versions of this and the preceding communication by Fellgett, Clark Jones and Twiss

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, November 16

Society of Chemical Industry, Pesticides Group (at 14 Belgrave Square, London, S W 1), at 9 30 a m —Symposium on "Pyrethrum"

Tuesday, November 17

University of London (at Queen Mary College, Mile End Road, London, E 1), at 1 30 p m —Prof C P Whittingham "The Challenge of Biology"

Institution of Electrical Engineers, Measurement and Control Section (at Savoy Place, London, W C 2), at 5 30 p m —Discussion on "Sequence Networks versus Summation Transformers for the Derivation of Single Quantities for Protective Relaying", opened by Mr C Adamson and Dr E A Talkhan

Research Defence Society (in the Physiology Lecture Theatre, University College, Gower Street, London, W C 1), at 5 30 p m —Prof Sir Solly Zuckerman, C B , F R S "The Inevitability of Science" (Twenty-eighth Stephen Paget Memorial Lecture)

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m —Dr C E Dalgliesh "Biochemical Aspects of Disorders of Aminoacid Metabolism" (Tenth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation Further lectures on November 19, December 1, 3, 8, 10)*

Institute of Physics (at 47 Belgrave Square, London, S W 1), at 6 p m —Dr R L F Boyd "Some Techniques and Results of Space Exploration"

Royal Aeronautical Society (at 4 Hamilton Place, London, W 1), at 7 p m —Dr J A Shercliff "Magnetogasdynamics"

Wednesday, November 18

Institute of Metal Finishing (in the Recital Room of the Royal Festival Hall, London, S E 1) at 9 30 a m —Symposium on "Progress in Polishing"

British Institution of Radio Engineers (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 3 p m and 6 p m —Half-day Symposium on "Electronic Digitizing Techniques"

Royal Geographical Society (at 1 Kensington Gore, London S W 7), at 5 p m —Prof M E L Mallowan and Mr David Oates "Fort Shalmaneser, Nimrud"

Royal Meteorological Society (at 49 Cromwell Road, London, S W 7), at 5 p m —Dr G B Tucker "Mean Meridional Circulations in the Atmosphere", Prof H Riehl "Exchange of Heat, Moisture and Momentum between Hurricane Ella (1958) and Its Environment"

Institution of Electrical Engineers, Supply Section (at Savoy Place, London, W C 2), at 5 30 p m —Dr J S Forrest, Mr P J Lambeth and Mr D F Oakeshott "Research on the Performance of High-Voltage Insulators in Polluted Atmospheres"

Institution of Mechanical Engineers, Nuclear Panel (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Discussion on "To What Extent Should Design Wait on Research for Nuclear Power Plant ?"

Wednesday, November 18—Wednesday, December 2

Building Exhibition (at Olympia, London) *

Thursday, November 19

University College (in the Anatomy Theatre, Gower Street, London, W C 1), at 1 15 p m —Dr M Mary Douglas "The Abominations of Leviticus XI (an Anthropologist's Interpretation)" *

Royal Society (at Burlington House, Piccadilly, London, W 1) at 4 30 p m —Special General Meeting to consider the Annual Report of the Council, followed by Scientific Papers

Institution of Naval Architects (at 10 Upper Belgrave Street London, S W 1), at 4 45 p m —Mr P R Crewe and Mr W J Eggington "The Hovercraft—a New Concept in Maritime Transport"

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W 1), at 5 p m —Mr F A Williams "Use of High Tension Separation in Dressing Jig Concentrate from Decomposed Columbite-Bearing Granite Nigeria", Mr M L Fitzgerald "Metallurgical Accounting and Control"

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly London, W 1) at 5 p m – Annual General Meeting Prof H Davenport "Some Recent Progress in Analytic Number Theory" (Presidential Address)

Royal Aeronautical Society (at 4 Hamilton Place London W 1), at 6 p m —Mr W P Smith "Some Recent Progress in Air Survey with special reference to Newly Developed Territories" (Fifteenth British Commonwealth Lecture)

Society of Chemical Industry, Road and Building Materials Group (at 14 Belgrave Square, London, S W 1), at 6 p m – Dr H F W Taylor "Aspects of the Crystal Structures of Calcium Silicates and Aluminates"

Thursday, November 19—Friday, November 20

Plastics Institute (at the Royal Institute of British Architects 66 Portland Place, London, W 1)—Conference on "The Influence of Plastics in Building"

Friday, November 20

British Psychological Society, Occupational Psychology Section (in the Department of Psychology, Birkbeck College, Malet Street, London, W C 1), at 1 p m – Dr John C Webster (U S A) Making Yourself Heard"

Institute of Navigation (at the Royal Geographical Society, 1 Kensington Gore, London, S W 7), at 5 15 p m —Mr C M Cade ' Radiometry, Radio-Astronomy and Infra-red Techniques"

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, London, W C 2) at 6 p m —Discussion on 'The Ordinary National Certificate a New Look", opened by Mr T Siklos

Institution of Electrical Engineers, London Graduate and Student Section (at Savoy Place London, W C 2), at 6 30 p m —Mr G J Waddon Plastic Cables in the Telecommunications Industry"

Royal Institution (at 21 Albemarle Street, London, W 1), at 9 p m.—Sir Lawrence Bragg, F R S ' Atoms and Molecules"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Assistant Lecturer or Lecturer in the Department of Philosophy—The Registrar University College of Wales, Aberystwyth (November 14)

Lecturer (with a good degree in biochemistry) in Endocrine Biochemistry, to undertake research into the endocrine aspects of carcinoma in human patients in the University Endocrine Unit at the Liverpool Radium Institute—The Registrar, The University, Liverpool 3 (November 14)

Lecturer (preferably with a veterinary qualification) in Pharmacology in the School of Veterinary Medicine—The Registrar, Trinity College, Dublin (November 16)

Joseph Lucas Student (with a good honours degree in some branch of engineering, physics or chemistry, and prepared to work for a higher degree), for research into the initiation of explosion in gases vapours and powder clouds, or into the mixing of powdered materials —The Registrar, King's College (University of London), Strand, London, W C 2 (November 20)

Head (with suitable experience and superior attainments in chemical research and analysis, and the ability to organize, lead and inspire a large scientific staff) of the Government Chemist's Laboratory, London—The Civil Service Commission, 17 North Audley Street, London, W 1, quoting Ref No S 5041/59 (November 24)

Granada Research Chair in Communication—The Registrar, University College of North Staffordshire, Keele, Staffs (November 30)

Lecturer in Organic Chemistry at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (November 30)

Lecturer in Physical Metallurgy at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (November 30)

Assistant Lecturer or Lecturer in Mathematics—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (December 1)

Lecturer (preferably with an interest in algae and fungi) in the Department of Botany, University of Natal, South Africa—The Secretary, Association of Universities of the British Commonwealth 36 Gordon Square, London, W C 1 (December 4)

Senior Lecturer in Pure Mathematics—The Secretary The Queen's University, Belfast (December 5)

Senior Lecturer or Reader (senior theoretical astrophysicist) in Physics in the Theoretical Group of the School of Physics, University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London W C 1 (December 5)

Lecturer and a Senior Lecturer in Applied Mathematics at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (December 7)

Lecturer or Assistant Lecturer in Mathematics at the University College of the West Indies – The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London W C 1 (December 10)

Professor of Physical Chemistry at the University of Natal South Africa—The Secretary Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (December 11)

Chair of Mechanical Engineering—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (December 12)

Graduate to carry out a field and laboratory research programme in Crop Physiology —Professor of Agricultural Botany, The University Reading, Berks (December 15)

Lecturer in Physiology at the University of Queensland Australia—The Secretary, Association of Universities of the British Commonwealth 36 Gordon Square London, W C 1 (December 15)

Research Fellow in the Department of Radiodiagnosis – The Registrar The University, Leeds 2 (December 19)

Associate Professor (university graduate with qualifications and considerable experience in some branch of the technology of wool production or wool commerce or rural extension, and interested in the application of science to the practical problems of the sheep and wool industry) IN WOOL TECHNOLOGY at the University of New South Wales, Australia—The Agent-General for New South Wales, 56–57 Strand, London, W C 2, and the Bursar, The University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia, marking envelope "University Appointment" (December 21)

SAVILIAN PROFESSOR OF ASTRONOMY—The Registrar, University Registry, Oxford (December 24)

ENTOMOLOGIST, Grade C (with a good honours degree in entomology (zoology), and with a particular interest in biological control work)—The Director, Commonwealth Institute of Biological Control, Science Building, Carling Avenue, Ottawa, Ontario, Canada (December 31)

AGRICULTURAL DEVELOPMENT OFFICER (aged 25–40, with considerable experience in arid/tropical agriculture based on well and flood irrigation) with the Aden Government—The Crown Agents, 4 Millbank, London, S W 1, quoting Ref M 3A 5857/T A

BIOCHEMIST, Basic Grade (graduate in chemistry, or Associate or Graduate Member of the Royal Institute) IN THE DEPARTMENT OF PATHOLOGY—The Group Secretary, Queen Elizabeth Hospital for Children, Hackney Road, London, E 2

SENIOR SCIENTIFIC OFFICER (with an honours degree in zoology, with postgraduate experience in entomology) at the West African Stored Products Research Unit, Federation of Nigeria, to undertake original investigations into problems associated with stored foodstuffs in Nigeria, and evolve methods of improving quality and reducing losses, with particular reference to losses caused by insect infestation—The Director of Recruitment, Colonial Office, London, S W 1, quoting BCD 153/14/012/T

SPECIALIST OR SENIOR SPECIALIST OFFICER, PLANT PATHOLOGIST (with a good honours degree in botany and at least two years postgraduate training or experience) in the Northern Region of Nigeria, for general plant pathology investigations—The Director of Recruitment, Colonial Office, London, S W 1, quoting BCD 63/408/039/T
